Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

London, E C.—Tenders will be received at the General Post Office, London, E.C., until noon on 28th inst. (a) for supply of red fir telegraph poles, to be delivered in London. King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (b) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed. The poles to be felled between November 1, 1895, and February 29, 1896, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections, from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender, containing all particulars, may be obtained on application to Mr. Chas. E Stuart, controller of stores.

RESULTS OF TENDERS.

Stafford.—The amount of the accepted tender of Messrs. Drake and Gorham, of 66, Victoria-street, Westminster, for wiring the Staffordshire County Infirmary, given in our last issue as £397, should, we are informed, be £403.

Harrogate.—Seventeen tenders were received for the electric wiring of the new baths (the wires to be carried in tubes or conduits embedded in a plaster, and to provide 433 lamps to be arranged in circuits), and the tender of Messrs. Paterson and Cooper, of London, for £412, was accepted; the tender of the National Telephone Company was also accepted for fixing telephones in four positions in the new building.

Richmond (Surrey).—Tenders for fire-calls extension to Kew and Petersham, for the Richmond Town Council, resulted as follows:

Newland and Co.	£371	0	0
Harrison, Coles, and Co.	317	5	0
Consolidated Telephone Company	299	10	0
J. Sax and Co.	250	0	0
For cables only.			
Callender Company (accepted)	165	6	0
For instruments only.			
Stewart	46	7	6

Croydon.—The following tenders have been received by the Town Council for wiring and supplying and fixing electrical fittings at the new Town Hall, Courts, and Free Library:

H. Binko and Co., 34, Leadenhall-street, E.C.	£1,124	15	0
Wenham and Waters, Paragon Works, Croydon (accepted)	1,253	0	0
S. J. Waring and Co., Limited, 181, Oxford-street, W.	1,325	10	0
Spagnoletti and Crookes, Goldhawk Works, Shepherds Bush	1,450	0	0
Vaughan and Brown, 16, Kirby-street, E.C.	1,455	0	0
Roger Dawson, Limited, 63, Berners-street, W.	1,467	10	0
Paterson and Cooper, 3, Princes-mansions, Victoria-street	1,530	10	0
Strode and Co., St. Paul's-churchyard, E.C.	1,537	0	0
Lund Bro. and Co., 123, Oxford-street, W.	1,548	0	0
New and Mayne, Palace-chambers, S.W.	1,5?0	0	0
Edmundsons, Limited, 19, Great George-street, S.W.	1,643	0	0
Hollingum and Saward, 31, Holborn-viaduct, E.C.	1,675	0	0
H. F. Joel and Co., 31, Wilson-street, Finsbury, E.C.	1,688	17	0
A. C. Hands, 194, Upper Thames-street, E.C., and Page and Miles, 60, Western-road, Brighton	1,743	5	0
Fowler, Lancaster, and Co., Albert Works, Birmingham	1,775	0	0
Graham and Biddle, 461, Oxford-street, W.	1,776	12	10
Peto and Radford, Hatton-garden Electric Works, E.C.	1,824	0	0
Laing, Wharton, and Down, 17, Gracechurch-street, E.C.	1,861	1	9
Rashleigh Phipps and Co., 102, Oxford-street, W.	1,880	0	0
Winfields, Limited, Cambridge street Works, Birmingham	1,980	0	0
Pettitt and Hards, 2, Duke-street, Adelphi, W.C.	2,070	0	0
Smeeton and Page, 63, Queen Victoria-street, E.C.	2,250	0	0
J. S. Cunnington and Co., 5, John-street, Adelphi, W.C.	2,439	0	0
Hirst and Co., St. Michael's-road, Croydon	2,685	0	0

Brussels.—The following were the tenders for the supply of cables and copper wire (bare and covered) for the Telegraphic Service, specification No. 24.

For 1,300 to 2,000 metres of house wires (two conductors), 1,200 to 1,600 metres ditto (six ditto), 300 to 400 metres of river cable (two ditto), 700 to 900 metres ditto (four ditto), 1,500 to 1,800 metres of submarine cable (six ditto):

	francs.
L. Hen et Cie., Schaerbeck	13,019
Felten et Guilleame, Mulheim	13,147
G. Boty, Brussels	15,055
Société industrielle des Téléphones, Paris	15 333
S. Hirschmann, Berlin	15,501
Clouth, Cologne	16,978

For 675 to 900 kilogrammes of annealed copper wire, diameter 1·2 millimetre; 200 to 300 kilogrammes ditto, diameter 1·6 millimetre; 300 to 450 kilogrammes ditto, diameter 2 millimetres; 155,000 to 200,000 metres of guttapercha-covered copper wire cased with white and brown cotton; 87,000 to 110,000 metres ditto cased with asphalted cotton; 30,000 to 55,000 metres ditto, with a layer of coloured incombustible cotton; and 2,500 to 3,500 metres of flexible two-wire conductors:

	francs.
L. Hen et Cie.	23,267
Even, Liège	23,675
Felten et Guilleaume	25,843
Clouth	33,681
Société industrielle des Téléphones	35,750
S. Hirschmann	38,553

London, E.C.—The tender of Messrs. F. A. Glover and Co., of 97, Queen Victoria-street, E.C., at £369, for the electric wiring of the Cripplegate Institute has been accepted. Mr. H. B. Jenkinson is advising the governors as consulting engineer.

BUSINESS NOTES.

Salisbury.—Steam was turned on at the new electric light works at Salisbury on Monday last by Mr. E. R. Dale, A.I.E.E.

Walsall.—The Town Council have decided to borrow £1,200 from the Qui Tercentenary Fund Trustees for electric lighting expenses.

London (St. George's).—The surveyor of St. George's, Hanover-square, Vestry is preparing a general report on the subject of the electric lighting of the district.

The Electric Light in South Africa.—Messrs. Delfos Bros., of Pretoria, have entered into a contract with the Bloemfontein Town Council for supplying the town with the electric light.

Electric Tramways in Brazil.—It is stated that the Companhia Ferro Carril Carioca has contracted with the General Electric Company of New York for electric cars on its tramway.

Birmingham.—There is a possibility of the Birmingham City Council giving consent to a trial of the overhead electric traction system upon the Nechells route by the Central Tramways Company.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 20th inst. amounted to £1,104, as compared with £888 in the corresponding week of last year, being an increase of £216.

Govan (Lanark).—The District Lunacy Board have discussed the question of the lighting of the new Hawkhead Asylum Hospital, but a proposal for a committee to enquire as to the introduction of electric light was lost.

Dover.—A special meeting of the Town Council is to be held on November 9 to approve of an application to the Board of Trade for a provisional order authorising the Corporation to construct tramways in the borough of Dover.

Western and Brazilian Telegraph Company, Limited.—The traffic receipts of this Company for the week ended October 18, 1895, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,009.

Wolverhampton.—The Coseley District Council having considered their surveyor's report on public lighting have decided to adopt gas, an amendment that the district be canvassed to ascertain if the majority of ratepayers were not in favour of electricity being rejected.

The Eastern and South African Telegraph Company, Limited, announces the payment by warrants, on November 1, 1895, of interest on the 4 per cent. Mauritius subsidy debentures. The transfer books will be closed from October 27 to November 1, both days inclusive.

Hartlepool.—With regard to the Hartlepool tramways, the track is being relaid, the electric connections made, and the trolley poles are being erected by the Electrical Construction Company. It is expected that the cars will be running by the end of the year.

Brockie-Pell Arc Lamps.—We have received from Messrs. Johnson and Phillips, of Charlton, Kent, and Union-court, Old Broad-street, E.C., a new catalogue of the Brockie-Pell arc lamps made by them, in which attention is directed to the greatly reduced prices of the lamps.

Hamburg.—A travelling bridge on the suspension principle across the Elbe at Hamburg is under contemplation. There will be three electric cars—two for carriages and horses, and one for foot passengers. The span is 1,350ft., and there will be a clear head of 130ft. above the river.

Heaton Norris (Stockport).—The Electric Lighting Committee of the District Council have discussed the subject of obtaining a provisional order for lighting this district with electricity, and a letter from Mr. Cobbett, clerk to the Wilmslow District Council, was read. The matter was deferred for further consideration.

City and South London Railway.—The returns for the week ended October 20 were £927, compared with £932 for the corresponding period of 1894, being a decrease of £5. The total receipts for the half-year 1895 are £13,701, compared with £13,863 for the corresponding period of 1894, being a decrease of £162.

Berliner Elektricitats-Werke.—The directors will propose at the ordinary general meeting of this concern to be held on October 30 that a dividend of 12½ per cent., against 10½ per cent. in the previous year, be paid. The net profit amounts to 1,596,459 marks, against 1,293,057 marks; and 830,264 marks, against 813,848 marks, are written off.

Digitized by Google

Harrogate.—It has been stated in the Town Council that the whole of the estimates for the electric lighting installation in the borough would amount to £27,000 instead of £25,000, as previously thought. The present contracts amount to £13,202. The town clerk has been authorised to borrow £2,000 in addition to the sum authorised at the last meeting—viz, £25,000.

Canadian Electrical Association.—At the fifth annual convention of this association recently held at Ottawa, the address of the president, Mr. K. J. Dunstan, dealt mainly with electrical works and improvements executed during the year. With regard to electric carriages, he considered that indications pointed strongly to our "being on the verge of a horseless age."

Cardiff.—We hear on good authority that the short interruption in the electric supply on Friday evening last was due to the breaking of a valve spindle in one of the engines. As the alternators were running in parallel, this accident temporarily stopped the supply; but, owing to the energy and promptitude of the engineers in charge, the pressure was on the mains again within five minutes.

Bristol.—On the suggestion of Mr. Howes, a resolution of the Kingswood Urban District Council, passed a month ago, was rescinded, and plans submitted by the tramways company for the extension of the line to Warmley-hill were approved. The added line will be double from the gates of the flower show field to the top of the hill, and will be laid in the centre of the road. Work has been commenced.

Electric Sign and General Advertising Company, Limited.—This Company was registered October 12, with a capital of £5,000 in £1 shares. Objects: to enter into an agreement with Messrs. G. C. Fricker and A. W. Poulton for the acquisition of the business carried on by them at 46, Queen Victoria-street, E C., as manufacturers of and dealers in electrical and other advertising apparatus, and to carry on and extend the same.

Wimbledon.—The District Council have received two letters from the Ratepayers' Association, enclosing resolutions opposing the electric lighting scheme, and appealing to the Council not to pass it until the ratepayers had had an opportunity of passing an opinion upon it. A letter was also received from the Local Government Board stating that the enquiry would take place as soon as the other engagements of the inspector would permit.

Colwyn Bay.—The District Council have unanimously resolved that application be made to the Board of Trade to grant to the Council a provisional order authorising the Council to supply electricity within the whole of the urban sanitary district of Colwyn Bay and Colwyn. It was further resolved that all the members of the Council be appointed a committee to carry out all necessary steps in furtherance of the resolution with power to act.

Ilfracombe.—The Ilfracombe District Council have decided that no further steps be taken in connection with the proposal to promote a Bill for securing the compulsory purchase of the gas company's undertaking. The Council are acting wisely in considering the alternative of introducing the electric light as a means of street illumination into the town, and the surveyor has been instructed to furnish a report on the subject of electric lighting.

The Aluminium Company.—The Aluminium Company, which secured the Falls of Foyers, is, it is stated, negotiating for the water power of the Falls of the Clyde. The Company propose to use the Bonnington and Corra Linn Falls, leaving Stonebyres alone. The negotiations have proceeded satisfactory so far as the Aluminium Company is concerned, although a slight hitch has occurred with one of the proprietors of the estates on which the falls are situate.

Halifax.—A large party, consisting of ladies and gentlemen, members of the Halifax Scientific Society, were conducted the other day through the borough electricity works by Mr. T. P. Wilmshurst, the electrical engineer. While the members were assembling in the office adjoining the works, some novelties in the way of incandescent lamps with tinted bulbs were objects of universal admiration, the effect produced by them being very pleasing and artistic.

Fulham.—The Vestry's Special Committee on Electric Lighting have given the clerk instructions as to inviting six expert electrical engineers to attend before them with a view of appointing one to advise the Vestry, at a fee of £50. The Vestry has decided to oppose the application of the Capital and Counties Electricity Supply Company, Limited, for a provisional order to supply electricity for public and private purposes with the area of the jurisdiction of the Vestry of Fulham.

New Cables in Lower Burma.—New cables have been laid to Diamond Island, seven miles, and across the Irrawaddy at Yandoon and at Myanoung. The first and last replaced faulty cables; the one at Yandoon was for the Yandoon Daimbyu circuit. Cables have failed again at Kemmendine, and it has therefore been decided not to lay new ones there, but to erect spans instead over the Hlaing and Paulang creeks, about a mile above the present crossing. The Kyauktan cable failed during the year and was abandoned.

New Cell.—We have received from the Chloride Electrical Storage Syndicate, Limited, of Clifton Junction, near Manchester, a price-sheet of their new "R" type cell, which is fitted with a new type of plate they have lately brought out. These cells are, we are informed, capable of being discharged at very high rates, and can with ease be charged in four hours; a great saving can therefore be effected in the time formerly necessary for charging. The price of these cells is, we understand, low compared with their great durability.

Queenstown.—The Town Commissioners have instructed their solicitor to take all necessary steps in "order to obtain a provisional order from the Board of Trade to enable the Commissioners to erect works and plant to supply electric light within the township." Mr. Campbell mentioned that Mr. Handley, of the firm of Handley and Shanks, Cork, had spoken to him of the desirability of erecting four arc lamps in the town as an experiment; and it was decided, subject to the expenditure being legal, to do this.

Swansea.—Mr. Viner Leeder gave notice of a motion rescinding the resolution of the Council adopting the electric lighting scheme. The Mayor said he must rule the motion out of order, as the matter had already been decided twice within a municipal year. Mr. Leeder said he would submit to the ruling. He understood that the Electric Lighting Committee had met since the last Council meeting, and that there were some suggested alterations. He did not know whether he was right. It was the only information he had received. If that was so he would willingly drop it and not press for information now.

Leeds.—A correspondent writes to a local paper: "Having travelled upon electric trams in several American cities during the last few weeks, I venture through the medium of your columns to suggest to the city authorities that they obtain information respecting the system now working in Detroit. The most prominent feature is the wonderfully smooth travelling which obtains there as the result of the rails being laid in concrete and welded together so as to form continuous rails, in some cases of several miles in length. I trust to find that in the early future Leeds will be in possession of one of the finest tram systems in the world."

Bradford.—The Corporation have received a further letter from Mr. Isaac Smith on the subject of the terms on which the Corporation should experiment with the Dvorkovitz oil-enriched gas. Mr. Smith offered to bear the cost of extra fire insurance premiums, if any. The letter was referred to the Gas and Electricity Supply Committee. Subsequently, on the minutes of this committee coming up for discussion, Alderman Morley proposed that the question be settled at once and Mr. Smith's offer accepted, but in view of the previous decision this was ruled out of order. The matter will accordingly go to the new committee to be appointed after November 9.

City of London Electric Lighting Company, Limited.—The revenue from the sale of current for public lighting for the quarter ending September was £3,182, compared with £3,141 for the corresponding period of last year; and for private lighting, etc., £11,600, against £7,676; the estimated income from other sources being put at £400, as compared with £416; making the total revenue £15,182, against £11,233, or an increase of £3,949. The equivalent of 8-c.p. lamps connected on September 30 was 170,827, an increase during the quarter of 11,577, the equivalent on the same date of 1894 being 114 031, and the increase during the corresponding quarter 13,724.

Indian Telegraphs.—The *Madras Mail* says: "The telegraph authorities deserve great credit for the promptness with which they have established through telegraphic communication between Madras and Bombay. The lines were submerged between the 370th mile and the Bori Bridge. A party started at once for the scene and divided at the 370th mile, half staying there, the rest with great difficulty going on to the Bori Bridge, carrying stores with them. They reached there yesterday, and by 3 30 p.m., after great trouble, and with the exercise of a good deal of ingenuity managed to rig up a temporary span and restore through communication, for ordinary and urgent messages at least, between Madras and Bombay."

Glasgow.—The Police Commissioners have considered the report of the Watching and Lighting Committee stating that, on the suggestion of Bailie Guthrie the committee remitted to a sub-committee to consider and report on the question of the electric lighting of the city, and particularly on the kind of lamp to be used for such lighting. Mr. Nelson said he was glad to see a remit to a sub-committee to consider the electric lighting of the city and the kind of lamp to be used. They had thus anticipated his motion referring to the unsatisfactory way in which the principal streets were lighted, and he would be quite content to accept it if the committee could add the name of Mr. Arnot to the committee. The Chairman said that would be done, and the report was then approved.

Bexhill (Sussex).—The Urban District Council have received from Messrs. Cope and Son a formal notice that Lord Cantelupe and another gentleman intend to apply for powers under the Electric Lighting Acts of 1882 and 1888 to introduce the electric light into Bexhill, and asking the consent of the Council to such an application. The consent of the Council, it appeared, was not really necessary, and was asked out of courtesy. Mr. Young saw no reason why the assent of the Council should be withheld if a clause was inserted giving the Council the power to purchase at a certain price at any time they might wish to do so. He moved an amendment to that effect. The amendment, having been seconded, was put and lost, the original motion being carried with two dissentients.

Spanish Customs Regulations.—The Spanish Chamber of Commerce in London, 23, Billiter-street, E.C., inform us that the said Chamber will prepare and certify in the Spanish language the certificates of origin of British goods to be sent to the Spanish kingdom in accordance with the new regulations issued by the Spanish Government, and which will be enforced from November 1 prox. To facilitate its despatch at the Spanish Custom Houses, this Chamber has, for the inspection of shippers, the Spanish Custom House tariff in both languages, Spanish and

Digitized by Google

English, with the equivalent weights and measures of the two countries. The form of the certificates to be given by the manufacturers and producers of goods to be shipped to Spain will also be provided by this Chamber.

Newcastle-on-Tyne.—The Town Improvement Committee of the Newcastle Corporation have definitely decided to recommend the City Council to adopt the cable system of tramways, and have drawn up a report for confirmation. It appears to the committee to be essential that, as far as practicable, the lines of tramway to be worked by cable should be double lines. The cost of laying the cable tramways comprised in the scheme, including engine-houses, engines, track, and conduit, but exclusive of cost or value of land for power station, is estimated at about £125,000 On the report coming before the Council for confirmation, a discussion took place, during which the Council was urged to follow the example of Leeds and adopt the electric system, and the meeting was adjourned to consider the matter further.

Liverpool.—The Marine Committee of the Dock Board have recommended that the Prince's Landing-stage should be lighted by electricity, at an estimated cost of £500, to facilitate the landing of passengers and luggage from the American liners. Mr. Bushell moved, and Mr. Gladstone seconded, the confirmation of the recommendation. Mr. Fernie asked whether it would not be desirable to extend the electric light along the whole length of the stage. It could be done for an extra £200 or £300. The Chairman: That is a matter which we will take into consideration. The recommendation was then confirmed. It was decided, at the suggestion of the Docks and Quays Committee, to provide two electric lights at the east side of the Canada lock and one at the west side of the new passage between the Canada and Hus kisson Docks, at an estimated cost of £500.

Islington, N.—The Electric Lighting Committee of the Vestry have reported that the sum of £60,000, the original estimate for laying down an installation of electric light in the parish, had been arrived at without professional assistance, and it had since been found to be inadequate. They therefore submitted an account of their expenditure up to the present date, which showed that a sum of £50,790 9s. 3d. had been spent on the works, and, in addition to the £15,000 they had in hand, they required a further amount of £25,000. The committee asked the Vestry's sanction for borrowing this amount from the London County Council, repayable within a period of not less than 42 years, at a rate of interest not exceeding 2½ per cent. per annum. After a long discussion the Vestry sanctioned the proposal to borrow the money. The Vestry have, in connection with their electric lighting scheme, already received applications for 9 237 8-c p lamps.

Denbigh.— Representatives from the Edison-Swan Electric Lighting Company have attended a meeting of the Lighting Committee of the Town Council and explained the terms upon which their company would undertake to supply the town with electric light—viz, that if the Council would find the money required, the company would build a station, supply all plant, etc, and take a lease for 30 years or any other term to be agreed on, work the lighting system for that term, and pay a rent for the same which would be sufficient to cover the initial outlay, depreciation, and interest, and at the end of the term the station and plant would become the property of the Corporation. They also explained that the electric lighting would effect a saving of 20 per cent. in the expenditure. The committee went into the matter, and it was resolved that it be laid before the whole Council. The whole subject was referred back to the Lighting Committee for consideration to report.

Barnet (Herts.).—The clerk to the Urban Council has reported that he had obtained information from several quarters bearing on the question of electric lighting. Mr. Schmidt moved that the letters should be referred to the General Purposes Committee. Mr. Martin Pooley seconded. The Rev. G Bampfield opposed, because, he said, that committee was, for such a question, unfairly and improperly constituted. If the letters must go to committee he asked that a special committee should be formed. He maintained that the General Purposes Committee had not had the whole question delegated to them. Four members had been returned on the recommendation of the Ratepayers' Association, and one of their first objects was to oppose anything like experimenting with electric lighting He contended that one-third of the committee should have been taken from these members, so that the question might be fairly treated. As a matter of fact, only one of them sat on the committee. The Rev. G. Bampfield alone voted against the motion to refer the letters to committee, and the motion was accordingly carried.

Weybridge.—The Urban District Council have received the following letter from the Board of Trade: "In reply to your letter enquiring whether the electric supply order can be transferred to the Urban District Council, and upon what terms, I am directed by the Board of Trade to refer you to the provisions of Sections 64-67 of the order, a copy of which is enclosed herewith." Of these sections the most important was the sixty-sixth, which is as follows: "The Board of Trade may revoke this order at any time, with the consent and concurrence of the undertakers and the local authority, upon such terms as the Board of Trade may think just." Mr. Chambers thought they had better let the matter drop. Mr. Bilney did not consider they should do that, and the Chairman remarked that it would cost £200 to get a new order. He (the chairman) thought they should see what arrangements could be made with the undertakers. Several members concurred with this view, and the clerk was instructed to write to Mr. Martindale, referring him to Clause 66, and asking upon what terms it could be arranged that the order should not be revoked, but transferred to the Council.

Brazilian Submarine Telegraph Company, Limited.—The report for the half-year ending June 30, to be submitted to the ordinary general meeting on October 30, states that the revenue amounted to £108,205, and the working expenses to £21,129. After providing £3,200 for debenture interest and sinking fund, and £1,790 for income tax, there remains a balance of £82,086, to which is added £4,324 brought forward, making a total of £86,410. A quarterly interim dividend, absorbing £19,500, has been paid, and £30,000 transferred to the reserve fund. The directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share, both free of income tax, which together will amount to £32,500, leaving a balance of £4,410 to be carried forward. The receipts include £1,500 dividend to December 31 last on the shares in the African Direct Telegraph Company, Limited. The various sections of the lines are in good working order.

Killarney.—The Asylum Committee have received a letter from the Board of Control informing the Governors that they will take the necessary steps to provide a suitable dining-hall for the asylum, and with regard to the contract to be made with the electric light company for the supply of the necessary current for lighting the asylum, they also beg to inform the Governors that this arrangement does not fall within the province of the Board of Control. It is a matter for the Governors to arrange through their solicitor, but if the Board of Control can give any advice with regard to the terms and conditions of this contract it will be happy to do so. Mr. Leahy proposed a resolution asking the solicitor to the Board, Mr. Downey, to approve of the draft agreement between the medical superintendent of the Board of Control and the electric light company for lighting the asylum. The resolution was adopted. Mr. Leahy handed in the following notice: "I hereby give notice that at the November meeting of this Board I shall move that we then complete the agreement with the Killarney Electric Lighting Company, the draft of which we have now sent to our solicitor for approval."

Brighton.—The Works Committee of the Town Council have again had before them the application of the Brighton and Rottingdean Electric Tramroad Company for permission to erect 13 steel poles on the foreshore of the borough. The settlement of this vexed question has been in abeyance for some time now. The company have the permission of the Board of Trade to the erection of the poles between Rottingdean and the borough boundary, but of course it is essential that the system should be continued to the terminus, and the consent of the Council is necessary to the erection of the poles along the small piece of the line which lies within the borough. The committee decided to again adjourn the consideration of the subject. On the occasion of the carnival and parade on Thursday evening, October 24, arrangements have been made for the illumination of the Madeira-road by two arc lights erected almost opposite the entrance to the Chain Pier. Mr. Wright, the superintendent of the Corporation electricity works, has also endeavoured to secure a searchlight to be affixed on the top of the Aquarium for use along the road, and a searchlight to be employed from the top of the shaft in Glo'ster-road to illuminate the space about the entrance to the Aquarium.

Dublin.—The project locally known as "Rathmines to the Sea" is in a fair way of realisation, judging from the practical and representative meeting recently held. On that occasion Mr. J. H. Ryan, M I.C E, who was accompanied by Mr A. E. Porte, electrical engineer, and Mr. E. Liller, traffic expert, explained the route of the proposed line, which would be as follows: Starting from the post office at Castlewood-avenue through Charleston-road, Ranelagh, Chelmsford-road, Appian Way, Clyde-road, to Ballsbridge, thence to Sandymount and Merrion. Mr. Porte explained in detail the system of electrical propulsion proposed to be adopted, which would entirely obviate the necessity of poles and overhead wires, a system which was rapidly being adopted on the Continent, as costing much less than that of horse traction, etc. Mr. Liller also laid before the meeting statistics showing that the probable earnings of the line, on a very moderate estimate, would be sufficient to pay 5 per cent. of the original capital outlay. It is understood also that a sub committee was nominated, and a guarantee fund opened, Mr. Mullen, manager, National Bank, Rathmines, having consented to act as treasurer. The line would extend from the head of Rathmines-road to Ballsbridge, where it would strike the existing electric line to Merrion. The cost is estimated at £14,000.

New Issue—The Castner-Kellner Alkali Company, Limited, has been formed with a capital of £300,000. in £1 shares, in view of an arrangement made between the Aluminium Company, Limited, of London, who are the owners of the Castner patents, and Messrs. Solvay et Cie., of Brussels, who are by purchase the sole owners of the Kellner patents (except for Austria), for the purpose of working in Great Britain, Ireland, and the British Colonies, excepting Canada, the combined patents of Mr. Hamilton Y. Castner and Dr. Carl Kellner, for the manufacture of caustic alkali and bleaching powder by means of the electric decomposition of salt or alkaline salts. The prospectus states that Messrs. Solvay authorise the Aluminium Company to announce that the two companies have agreed to exchange their patents; that the working of the Castner-Kellner processes has been reserved to the latter for the United Kingdom and the British Colonies; that all improvements will be exchanged for a term of 12 years; and that the two firms intend to work in accord on commercial matters during that period. The purchase price to be paid to the Aluminium Company for the patents and the benefit of the agreement with Messrs. Solvay has been fixed at £125,000, payable as to £25,000 in cash and £100,000 in fully-paid shares.

Digitized by Google

It is said that the Castner process has been successfully worked for a year past at the Aluminium Company's establishment at Oldbury, near Birmingham.

Traction Companies in Philadelphia.—After deliberations extending over a period of two months, the big traction amalgamation has finally been consummated and the three extensive local street railway systems—the Philadelphia, Electric, and People's—joined together under the title of the Union Traction Company of Philadelphia. All the necessary papers have now been executed, and the lease of the Philadelphia Traction Company to the Union Company has been signed by Presidents John Lowber Welsh and Peter A. B. Widener. The deal was virtually effected two months ago, but since that time obstacles have arisen in the negotiations that prevented their consummation then ; but the last stumbling-block has now been surmounted, and the three big lines, forming the most extensive street railway system in the country, will be operated under one executive head. By the terms of the lease the Philadelphia Traction Company, including all its allied lines, controlled or owned. will be leased to the Union Traction Company for 999 years, the Union Company to assume virtually all the obligations now binding upon the Philadelphia Company, and to pay the latter company a rental which will yield the stockholders dividends of 8 per cent per annum. All that is now necessary to formally carry into effect the triple agreement is the action of the People's Traction Company stockholders on the question of reducing the capital stock so as to come within the provisions of the Act of Assembly. The deal as ratified forms the greatest single system of street railway lines in existence, with about 425 miles of road now operated, and a combined capitalisation in stock and bonds, including that of all the subsidiary companies, of more than £108,000.

Exeter.—Mr. Domville had the following notice of motion on the agenda at the last City Council meeting : "That a committee be appointed to have charge of the electric light undertaking when acquired by the Council." He stated that the terms of the resolution did not altogether meet his views. What he wanted was a committee to confer with the electric light company and to watch over the interests of the Council He would move, with the permission of the Council : "That on the confirmation of the purchase of the electric light undertaking a new standing committee be appointed to take charge of the electric light undertaking and the lighting of the city generally, and that meanwhile a committee be appointed to confer with the electric light company on any question of the repair or renewal of any of the plant." Mr. Wreford seconded. Mr. Jarman thought the resolution was premature. A short time ago they decided to reduce the number of their committees, and now it was proposed to make an increase. He considered that it would be better to appoint a sub-committee from the present Lighting Committee to attend to this matter, and he moved an amendment to that effect The Town Clerk said if a sub committee were appointed it would have to report to the Standing Committee who would have to report to the Council. What was wanted was a committee with greater power. Mr. Varwell thought they should leave the control of the present undertaking to the discretion of the electric light company, and not interfere with a thing they knew very little about. Eventually it was decided to appoint the following special committee to confer with the electric light company on any question of repairs or the renewal of any plant : Aldermen Andrew, Peters, Houlditch and Domville, Councillors Ham. J Gidley, F J Williams Wreford, Peters, Fulford, Perry, Surridge, and Linscott

Bolton.—The Gas and Electricity Committee of the Corporation have discussed the question of lighting the intended new station for Bolton, and also the charges for the supply of electricity to large consumers. The price per unit is to remain at 6d., as before, with a discount of 10 per cent. for cash, and the following revised scale of special discounts was approved of, the net price per unit being as follows :

Consumption per quarter.	Special discount, per cent.	Net price per unit
Under 250 units	—	5 4d
Between 250 units and 500.....	2½	5 265d.
,, 500 ,, 750.....	6	5 13d.
,, 750 ,, 1,000.....	7½	4·995d.
,, 1,000 ,, 1,250.....	10	4 86d.
,, 1,250 ,, 1,500.....	12½	4 725d
,, 1,500 ,, 1,750.....	15	4·59d.
,, 1,750 ,, 2 000.....	17½	4 455d.
,, 2,000 ,, 2,250.....	20	4 32d.
,, 2,200 ,, 2,500.....	22½	4·185d.
Over 2,500 units	25	4 05d.

The railway company recently enquired what allowances the committee were prepared to make for the supply of electricity, and it was decided to furnish them with a copy of the revised scale. At the same meeting a letter was read from the secretary to the Board of Trade inviting the attendance of representatives from the Corporation at a meeting to be held in London on November 19, to consider the revised regulations and prices to be issued by the Board of Trade for the supply of electricity. The chairman (Alderman Miles, J P.) and the engineer (Mr. J. H. Rider, M I.E E.) were deputed to attend the meeting. The question of connecting the electricity works by telephone with the National Telephone Company was left to the chairman and vice chairman.

Douglas Southern Electric Tramways, Limited —This Company has been formed with a share capital of £50,000 and has acquired an exclusive concession for the construction and operation by the overhead wire system of an electric tramway upon the Douglas Head Marine Drive at Douglas, Isle of Man, upon the terms of paying to the Marine Drive Company one penny for each passenger entering upon the drive with a current tramway ticket. The capital is divided into 30,000 7 per cent. preference shares of £1 each, and 20,000 ordinary shares of £1 each. The present issue consists of 20,000 preference and 10,000 ordinary shares, the remainder being left unissued for future extension. The shares are offered at par, payable 5s. on application, 5s on allotment, and 10s. on December 1 next. The Douglas Head Marine Drive has been completed from the entrance gates on Douglas Head to Castletown-road, and work is being actively pushed forward upon the completion of the drive to near Port Soderick. The drive as completed is a fine boulevard, about 40ft. in width, running along the edge of the cliffs at a considerable height above the sea, and commands the finest marine views in the neighbourhood of Douglas. The concession is for a period of 10 years from April 2, 1895, at the expiration of which the Douglas Head Marine Drive, Limited (grantors of the concession), have the option of paying to the Company the sum of £30,000 for the first 2½ miles constructed, and a further sum at the rate of £10,000, or a proportionate part thereof, for every subsequent mile or part of a mile, or to extend the concession for a further period of 21 years upon agreed terms. The terms of the concession are such as to prohibit any other vehicles from taking up passengers upon the Marine Drive, and permit all holders of current tramway tickets to enter upon the drive free of charge to such holders. The great number of visitors that are annually attracted to the Isle of Man will be a constant source of revenue to the Company, and this number is increasing, being larger for the present year than for many years previous. It is confidently expected that most of the visitors will avail themselves of the opportunity which the tram system will afford of seeing the numerous places of interest.

Douglas (I.o.M.).—In consequence of the recent visit to London of the directors of the Manx Northern Railway Company, a rumour is circulated to the effect that the line had been sold. It is said that the purchasers are the Isle of Man Tramways Company, who have an electric system to Laxey from Douglas, the object being to extend the electric tramway from Laxey to Ramsey, to convert the present railway into an electric line, and connect Peel with Ramsey. No confirmation of the rumour is to hand. The Manx Legislative Council have considered the indenture of agreement between the Douglas Town Commissioners and the Tramways and Electric Power Company for a renewed lease of the bay tramways, and also a Bill to empower the construction of a cable tramway system by way of Prospect-hill to the upper part of the town The indenture provides that the company shall pay the Commissioners for the concession 15 per cent. of the gross yearly earnings of the bay tramway, the total sum not to amount to less than £1,500 any year, and further to construct a cable tramway to the upper part of the town and pay 5 per cent. of the gross earnings of the same after a lapse of seven years. Mr. Crippin appeared in person in opposition to the scheme and cross-examined witnesses to show that he had made a better offer than that of the company. The Commissioners' clerk replied to the effect that Mr. Crippin's offer had been considered by the Commissmissioners and not thought so good as that of the company. The Council only called for evidence to show that the tramway to the upper part of the town could be constructed without endangering the ordinary traffic, and were satisfied that the monetary consideration for the lease was sufficient. Deemster Drinkwater and the Clerk of the Rolls raised a strong objection to the tramway being laid on Prospect-hill, which is only 18ft. wide at its narrowest part, but on counsel for the Commissioners stating that it was the immediate intention of the Commissioners to widen the hill to 42ft. intimation was given by the Governor that the Council would confirm the indenture if the Commissioners would add a proviso to carry out the widening before May next, and the Council was adjourned in order that a proviso might be prepared and submitted. The lease to the tramway company is therefore as good as approved.

Electric Lighting in Calcutta.—It is quite refreshing to see that the Calcutta Commissioners have at length decided to give serious attention to this matter ; and that a call for fresh tenders for lighting the Harrison road has been recommended by the special committee engaged on this important subject. Several costly and unsatisfactory experiences have been gone through of late in such enterprise, and it behoves those concerned to guard against similar failures for the future, by the establishment of the best obtainable description of installation. That this cannot be procured at low first cost goes without saying; for the essence of success in these matters lies in a combination of highest qualities of machinery and plant, and that experience in erection and working which only an extensive first-class practice can afford. We are happy in noting the weight which the committee attach to the selection of conductors for the current ; for in the wise choice of the construction of these, and of the fashion in which they are laid, will indeed rest one main pillar of the edifice. Without a reliable system of distribution the best machinery would be useless ; and, as the percentage of cost falling to the mains is considerable, a most cautious choice and careful test of such cannot be too strongly recommended. We are somewhat surprised that the committee should have considered the possibility of using overhead lines, and that, apparently, they should have received some support in this from their expert. Far be it from us to condemn the aerial line in general ; for long unbranched main lines to distributional centres, suburban connections, and transmissions over country districts, nothing but overhead lines are at present economically imaginable ; but the installation of such in city thoroughfares cannot be too strongly condemned. With reference to the armoured and high-insulation resistance cable, which is now

Digitized by Google

largely used in Europe, such cables are naturally expensive as regards first cost. This consideration is, however, more than outweighed by their great reliability and the low cost of upkeep and amortisation, ascertained in practice to be about 3 per cent. per annum on the value. We have one more remark to make concerning the choice of the system of lighting to be employed. In a number of places the endeavour has been made to successfully combine two or more systems (for instance, series arc—and alternate-current incandescent—lighting) under the impression that economy in working would be the result. We will not deny that, under certain rare circumstances, economy might be obtainable, but we should certainly deprecate any attempt of the kind in India, where success will be greatly dependent on the simplicity and uniformity of the control of and attendance to the generators and every other portion of the installation.—*Indian Engineer* of September 28.

New London Mains.—The report of the Highways Committee of the London County Council on Tuesday, stated that they had considered a notice, dated September 26, 1895, from the London Electric Supply Corporation of intention to lay low-tension distributing mains in Ebury-street, Victoria-square, and Buckingham Palace road. The mains will consist of rubber-insulated cable drawn into 3in. iron pipes, and are for a low-tension supply at 100 volts. They recommended that the sanction of the Council be given to the works. They also approved two further notices from the same company: (*a*) dated October 4, 1895, of intention to lay distributing mains in Grosvenor-mews, across Grosvenor street, Avery-row, South Molton lane and street, and Davies-street; (*b*) dated October 7, 1895, of intention to lay mains in Upper Russell-street and Lamb-lane. and a notice, dated September 25, 1895, from the Metropolitan Electric Supply Company of intention to lay mains in Elgin avenue and terrace, Portsdown-road, Canterbury-terrace, Maida-vale, Carlton vale and hill, Hamilton and Upper Hamilton terrace, Marlborough-place, Abbey road and gardens, Violet-hill, Abercorn-place, Nugent-terrace, Hill-road, Alma-square, Hamilton-gardens, Garden-road, Grove End-road, Hall-road, Circus-road, Elm Tree-road, Melina-place, Warwick-place, Sutherland-avenue, Amberley-road, Shirland-road, Warwick-road, Castellan-road, Formosa-street, Bristol-gardens, Clifton gardens, villas, and road, Warrington-crescent, Randolph-road, Portsdown-road, Lanark place and villas, Canterbury-terrace, Clarendon gardens and terrace, Edgware road, Maida hill West, Park-place-villas, Maida-vale, Compton-street, Campbell street, Howell-street, Cuthbert-street, Hethpool-street, Hall-place, Richmond-street, Lyons-place, Carlisle-street, Aberdeen-place, Northwich-terrace, St. John's Wood road, Hamilton-terrace, Cunningham-place, Warwick-place, Gloucester-terrace. A large part of the works referred to in this notice has been approved by the Council on previous notices of the company, but not carried out within the time specified in the notice of approval. The same company has also given a notice, dated October 7, 1895, of intention to lay mains in South-street Thayer-street, Mandeville-place, and James-street, and in Oxford street between James-street and Stratford-place. They further approved a notice dated September 30, 1895, from the County of London and Brush Provincial Electric Lighting Company of intention to lay pipes across High-street, Clapham, in two places; East-hill, High-street, and West-hill, Wandsworth, in two places; Upper Richmond road, in six places; High street, Putney, in two places; Putney-hill, in three places. Also a notice, dated October 9, 1895, from the Charing Cross and Strand Electricity Supply Corporation of intention to lay mains in Bull-inn-court, across and along the Strand, and in Salisbury-street. The proposed work is unobjectionable, but the committee think that the work in the Strand should be carried on by day and by night until completed. Also a notice, dated October 10, 1895, from the House-to-House Electric Light Supply Company of intention to lay low-tension mains, partly in 3in. pipes and partly in conduit, in Cranley-place and Onslow gardens and mews.

The Proposed Dorby-Ashbourne Electric Railway.—A meeting has been held to consider the proposed electric railway to Ashbourne from Derby, Mr. C. E. Newton, J.P., presiding. Mr. John Shaw, jun., explained the scheme. The railway was to be on the overhead system, and it was proposed that the line should be connected with the existing Derby tramway, which terminated on the Ashbourne-road, and thence it would run through Mackworth, Kirk Langley, and Brailsford, into the town of Ashbourne, terminating near the bridge. On only one portion of the line was there a really stiff grade, and that was for a mile at the Ashbourne end, but there was not any difficulty in getting over that. It was suggested that the line should be laid on the western side of the road through nearly the whole length, as there was ample room, but through the villages it would probably have to run down the centre There were telegraph poles placed at that side of the road, but there would not be any difficulty in obtaining power to remove them at a small cost. The permanent way could be laid at a cost of about £2,000 per mile. Paving would only be laid where absolutely required by the authorities. In all probability it would only be insisted upon through the villages, and a small portion at each end of the line—in Derby and Ashbourne. Electric signalling would be adopted to enable the crossings to be placed at as great a distance as possible from one another. Turn-outs and fixed stopping-places would be made where necessary, but a car could stop anywhere to take up or set down. The rolling-stock necessary for a line of that kind would consist of motor-cars, trailers, and goods cars. A motor car would have to be equipped with motors of 20 e.h.p. each. These cars would cost approximately about £600 each. Trailing cars, which would only be used in summer time, would cost about £200 each. The goods cars, specially fitted up, would cost about £100. All the cars would be lighted by electricity. It was proposed to build the generating station near the Brailsford Brook, about 7½ miles from Derby, as that seemed to be the best site, the heaviest part of the road being at the Ashbourne end. If sufficient hydraulic power could be obtained from the brook, a large saving might be made in generating the current. The following was a rough estimate showing the cost of the line: Cost of permanent way, including the cost of materials, laying, etc., £25,600; overhead equipment, £18,600; generating station, including land, buildings, engines, etc., £12,000; rolling-stock, including six motor cars, six trailing cars, and six goods cars, £6,100—total, £62,300. The maintenance of this line would be very small and the assistance it would be possible to give to the County and District Councils in delivering road materials would approximately pay for this. It was proposed to run the trains every hour probably, but at any rate as often as the traffic demanded. There would be depôts for goods, but not regular stations. The Great Northern Railway Company had decided to render them every assistance, and had agreed to allow them to run right into their goods yard; and the Electrical Construction Company had told him they would find a certain amount of money. They would, of course, invite tenders for the work. A resolution in favour of the railway was carried unanimously, and the Chairman said that the next matter was to have a certain amount of money subscribed, as he should like to see the £700 necessary to obtain an Act raised without having to go to any company.

Hampstead.—The Lighting Committee of the Vestry have recommended that a main for private lighting be laid down in Boundary-road, at a cost of £156. This was adopted. The same committee also recommended that the engineer be empowered to order 12 house-connection boxes, at a cost of £3. 16s. each. The recommendation was adopted. The committee recommended that the Willesden District Council be informed that, in consequence of the letter of their surveyor, the Vestry have again carefully considered the question of lighting the High-road, Kilburn, with electric light, and are strongly of the opinion that the arc lamps should be 24 in number, and placed on rests in the middle of the road; that by this arrangement the traffic would be regulated, rests at regular distances would be provided for the safety of the public, and the illuminating power of the lamps would be of the greatest efficiency; that the Vestry find (*a*) that the estimated cost of the 24 arc lamps, fixing, rests, and the cable connections to the Vestry's mains is £1,009. 4s., and (*b*) that the estimated cost of running these arc lamps is at the rate of £29. 13s. 6d. per arc lamp per annum; that the Vestry are willing to light the High-road, Kilburn, with electricity, on the condition that the Willesden District Council pay half the cost of the installation (*a*), and half the cost of running the lamps (*b*). The motion was carried. The same committee recommended that Mr. Bateman, of Finchley-road, be informed that the Vestry will grant him permission to light his outside lamp with electric light, provided he will take the supply of electricity from the Vestry, and sign the usual agreement. The recommendation was adopted. The committee recommended that the application of the three assistant electrical engineers at the central station for an increase in their salaries be not entertained. Mr. Johnson suggested that the application should be considered at the usual time for such applications to be sent in—viz, in January. The recommendation was adopted. Mr. Thwaites said that at the present time there was an equivalent of 17,000 8-c.p. lamps fixed in the premises of the Vestry's private customers, and now they had applications in hand for over 3,000 more. Mr. Johnson asked if the engineer could tell the Vestry what was the amount of the loss of electrical current between the quantity produced at the central station and that consumed by the customers The Chairman: Notice should have been given of such a question. Shortly afterwards Mr. Johnson, pursuant to notice, rose "to draw the attention of the Vestry to the absence from the recommendations of the Lighting Committee of any proposals to extend the public lighting by means of the electric current, and to request them to report thereon." He said that, had his question been answered, there would have been no need for this motion. He was informed, however, that the loss of current was as much as 66 per cent., and, if that were so, they could well understand why the Lighting Committee had not brought forward any proposals for the extension of the public lighting. He had been told by a man who ought to know that where the electric light was used in the streets the shopkeepers were bound for self-protection to have it inside their shops. Mr. Boyce seconded. Major-General Young said there was nothing in this proposal. There was already a resolution of the Vestry that only three roads were to be lighted by electricity at present—the Finchley-road, High-road, and Haverstock hill and High-street. Finchley-road was lighted by electricity, the proposal to light the High-road had been discussed that evening, so that there only remained one other of these thoroughfares It might be asked, "Why don't you go on with this?" Well, it was in the hands of the Lighting Committee, and they had better leave it there. Only four voted for the motion, which was lost.

Brandon and Byshottles (Durham).—The Chairman said at the last meeting of the Urban District Council that at the previous meeting they had before them the estimates of the Corlett Electrical Engineering Company, but lack of time then prevented the consideration requisite for so important a subject. He had since had the opportunity of looking through the estimates, and that perusal had confirmed him as to the practicability of the views put forward by him at the last meeting on the subject. In the East Ward the North Brancepeth Coal Company had made an offer by which the Council would merely be charged a sum to clear actual attendance and lubrication of the requisite

Digitized by Google

machinery for producing the electric light. He hoped they would be as successful in the other wards. He counselled them to go very carefully into the figures which would be submitted to them and see what the proposal meant to the district, and whether economically electricity was to be preferred to gas, and so forth. The Clerk said any decision that the Council could come to that day would only refer to the main thoroughfares, and nothing else whatever. If they decided to light the district by electricity, and also to light private streets and private premises, they would have a considerable amount of further procedure to go through before they were in a position to assume these powers. They would have to apply to the Board of Trade for a license or secure an Act of Parliament. A Board of Trade license only lasted for seven years. and there were considerable formalities to go through. The Chairman then furnished the Board with certain figures relating to the project. It was proposed in the East Ward to erect 74 lamps for the illumination of the public thoroughfares in that ward. Seventy-four gas lamps complete at £3 per lamp totalled £222, that being within the Durham Gas Company's estimate. The cost per annum of each lamp, to be lighted at dark and extinguished at 12 p.m., was about £1. 17s, making a total for the 74 lamps of £136 18s. Lighting and repairs was estimated at about 6s. 6d. per lamp — total, £24. 1s. The total amount required to clear the cost of the first year's lighting by gas was therefore £382 19s The estimate for 74 electric lights for the same ward was as follows : An 85-light dynamo, with engine, lamps, and everything complete £444. The cost for running per annum, £60, making a total of £500. Comparing the cost the first year as between gas and electricity, there was a difference of considerably over £100 in favour of gas But in subsequent years electricity would only cost them £60 per annum, hence the Council could easily see the advantage of electricity over gas If electricity were adopted, the Council would in three years recoup itself for the extra initial cost of plant. The Chairman said for the centre ward there was only one scheme submitted, and that was for lighting it with the electric light. It was proposed to erect 18 lamps. The cost of the necessary plant (including a dynamo for 85 lights) and 18 posts, fittings, etc., was £269 The cost of running would be £75. 2s. per annum. At this point an estimate for providing the necessary plant for lighting the East Ward with electricity was read from Messrs Ernest Scott, Mountain, and Co , of Newcastle They would provide an installation to maintain 50 lamps, each of 32 c p., for £480. On the motion of Mr. Willis, seconded by Mr Barnes, it was unanimously resolved, "That the main roads and main streets in this Council's district be lighted by electricity. subject to satisfactory estimates as to the cost being obtained, and subject to license of Board of Trade being obtained if necessary. That the surveyor, in conjunction with the Works Committee and Councillor Green, be instructed to prepare plans as to the proposed scheme for lighting the main roads and streets in the Council's district. That advertisements be inserted in the three Newcastle papers and in the two Durham papers, inviting tenders for provision of electric lighting in accordance with the particulars to be prepared by the surveyor and the Works Committee."

Hanley.—Mr. G. W. Willcocks, M I C.E , Local Government Board inspector, held an enquiry at the Town Hall, Hanley, on the 16th inst for the purpose of investigating an application by the Hanley Town Council for permission to borrow the sum of £20,000 for the purpose of extending the electric light works and mains. The Town Council was represented by Aldermen E. J Hammersley (mayor), J. Shirley (chairman of General Purposes and Electric Light Committee), T. Hampton, Councillors W. O'Keeffe, M. Huntbach, J. H. Ball, J Turner, T. Pickin, A. Wood, J. Goodson, M. Tunnicliffe, and A P. Miller, and A. Challinor (town clerk), J. Lobley, M.I.C.E. (borough engineer and surveyor), C. A. Cowell and C. J. Sutherland (electrical engineers and joint managers of electricity works) The enquiry was opened by the Town Clerk, who stated that the population of the borough was estimated at 56,000, and that the assessable value was £182,238, with an outstanding debt of £195,460. Included in that debt was £30,000 for electric lighting—namely, £21,000 for works and mains £1,000 for meters, etc., £3,000 for wiring all the Corporation buildings, and £5,000 for additional 300-kilowatt steam alternator and condensing apparatus. The present application was not opposed. It was made under the Electric Lighting Act, 1887, Section 8, and the purpose of the proposed loan was to extend the buildings, boiler plant, and switchboard required for the new alternator, and to extend the mains in different parts of the town. So far the Corporation had limited the supply of energy to consumers within the compulsory area. The demand for light was increasing continually, and was so great that although the markets were wired and fitted up it was not considered safe to connect them with the mains until further generating plant was provided. The result of the first six months' working ending December 31 last was that £31 was realised over the working expenses, and interest and sinking fund. The borough engineer and surveyor, and the Corporation electrical engineer, presented a report, which was unanimously approved at a Council held on April 30 last, and of which the following is a summary : (No. 1) Extension of mains to Market, Bath, Hope, Clough Charles, Trinity, Stafford, Tontine, Jasper, Bethesda, and Broad streets, Etruria, Regent, Hope, Victoria, Avenue, and Park roads, Piccadilly, Pall Mall, Birch-terrace, Snow-hill, and Park-avenue. These include high and low pressure mains, and for a second circuit of 30 arc lamps. The estimate for the above cables, including laying, is £5,508. (No. 2) Extension of the buildings at the generating station (leaving room for an additional boiler, condenser, and steam alternator when the same are required). Two new boilers and appurtenances, 16 sub-stations, 20 transformers, 25 junction-boxes, and 30 arc lamps and posts. The estimate for No. 2 list is £5,900. (No. 3) Two Ferranti rectifiers for both the present circuit of 30 arc lamps and for the new circuit, the present arc dynamos and engines being retained as reserve ; also 30 incandescent street lamps complete on new roads round the park, and 60 ditto in other parts of the town where mains are being laid ; extension of switchboards, and excavations and railings at works. The estimate for No. 3 list is £1 242 (No. 4) In consequence of the demand for energy within the compulsory area, considerable extensions have been made to the machinery, mains, sub stations, and transformers, amounting to £2,650, and to the buildings, furniture, excavating, drainage, and formation of ground, amounting to £2,060 ; sundries, £200 ; total for No. 4, £4,850. (No. 5) Provision for contingencies £1 000, special regard being to mains being laid to supply manufacturers with motive power. (No. 6) Meters and switches provided on consumers' premises, for which rental is paid ; estimate £1,500, including £250 already expended. Total for present application, £20,000. Mr. Lobley gave a detailed explanation of the purposes for which the money was needed, and Messrs. Cowell and Sutherland showed the increase in the number of lamps connected, which was considerably above the present capacity of the generating plant—namely, 10,000 8-c p. lamps The enquiry then terminated, and the inspector subsequently visited the works and proposed new lines of mains and arc lamps.

The Brighton and Rottingdean Seashore Electric Tramway. We have often referred to the progress of this interesting undertaking. A correspondent of the *Daily News* writes : From the Aquarium to Kemp Town a little electric railway, designed and carried out by Mr. Magnus Volk, has been running for some years It runs along the beach above high-water mark in some places, and on trestle bridges in others. The force is supplied by an engine and dynamo at the Kemp Town end. and conveyed along the line by a third line. The railway to Kemp Town has been a financial success, and gives a very efficient service, but the plan is obviously not one which could be repeated on a bigger scale. It certainly could not be extended to Rottingdean. In the three miles between the terminus of the existing electric railway and Rottingdean, there is practically no beach which is not covered at high tide. To construct a long viaduct would have been too expensive, and when a gale is blowing from the southward no viaduct would have been very safe The ups and downs on the cliff top made a railway by that route also a somewhat serious undertaking. But Mr. Volk was determined to run an electric railway eastwards to Rottingdean. In his necessity he hit upon an entirely novel idea. He would run his railway on the foreshore, slightly above low water mark, and 14ft. below the sea at its high-water level. His railway carriage would be a long legged thing running on lines which for the greater part of the 24 hours would be beneath the water. His stations at each end would be piers. Mr. Volk went to Parliament for powers and in 1893 an Act was passed authorising the construction of a tramway with a gauge not exceeding 24ft , to be worked by electricity between Brighton and Rottingdean. By the May of 1894 he was at work, and by next Easter he hopes to open the line for traffic In order to give stability to so tall a carriage running through a sea not free from tidal currents a broad base was necessary. At first Mr. Volk thought two rails 24ft. apart would be enough, but the expansion and contraction of tie-rods 24ft. long would have been considerable. Instead, therefore, of two rails connected by tie rods, the line has been constructed with four parallel rails, running in pairs. The breadth of gauge between the outer rails is 18ft. Each pair of rails is constructed and laid separately. The car will run on all four rails, each pair of rails serving the purpose of a single rail on an ordinary line. Each pair of rails is supported by concrete blocks mortised to the rock below. When the railway was designed and begun the rock was covered with sand to a depth in some places of 7ft., and the mortising of the blocks to the rock was naturally made much more difficult by the necessity of clearing away the running sand in the brief working day of two or three hours while the tide was far enough out to render work possible. During the storms of last winter, however, the whole stretch of coast was for the first time in the memory of man denuded of sand. The sand is now slowly being replaced by the sea on the shore which the storm laid bare It speaks well for the strength of the permanent way that no part of it was in the least injured by the storms. The concrete blocks were all made on the spot, and the work was done under such conditions of haste that the materials often could not be cleared away before the tide came. All but 400 yards of the permanent way has now been completed. The steepest gradient is 1 in 300, and the sharpest curve a radius of half a mile. The car, which was designed by Mr. St. George Moore, 17, Victoria-street, Westminster, who acts as engineer to the company jointly with Mr. Volk, is built by the Gloucester Wagon Company, and is specially adapted to the four rails. Each of its four main supports is a 12in. steel tube running on a four-wheeled bogie. There will thus be 16 wheels. The leading bogies will be driven by vertical shafts inside the steel tubes. The deck of the car is to be 23ft. high, and thus well out of the reach of any ordinary waves. The deck will measure 46ft. by 22ft., and will carry a saloon measuring 25ft. by 13ft. It is expected that some 100 to 150 passengers may find room in the single car. The railway will start working with one car only, but another will doubtless be added, with any improvements which practical experience may suggest. It was at first intended that the motive power, which will be supplied by a large Crossley gas-engine worked by producer gas housed in an engine-room excavated in the cliff at the Brighton end, should be conveyed by accumulators on the car itself. No power, therefore, was taken in the Act of Parliament for the

Digitized by Google

erection of poles. It, however, became clear that, to make the undertaking a commercial success, the electricity must be carried by wires and that poles must be laid along the foreshore for this purpose. The Board of Trade, who administer of behalf of the Crown the greater part of the foreshore, readily gave their consent to the erection of poles, charging a nominal rent of £1 a year in addition to the £12. 10s. which they receive for the permanent way. The tramway company are now awaiting a similar consent from the Brighton Corporation, who own one-sixth of the three miles of foreshore. Some members of the Corporation fear that the poles will be unsightly. If the Corporation refuse their consent, the company must go again to Parliament. The company, who have done the work without the intervention of a contractor, believe that the total cost of the line will not much exceed the £25,000 which they obtained power to raise.

PROVISIONAL PATENTS, 1895.

OCTOBER 14.

19245. **Improvements in dynamo-electric generators and motors.** Reginald Wood, 28, Southampton-buildings, Chancery-lane, London.

19256. **An improved electricity meter for registering the amount of current consumed on direct or alternating polyphase, triphase, or quadruplephase circuits.** Frederick John Beaumont and Frederick Hallows, 166, Fleet street, London.

19260. **Improved electrical apparatus for preventing the collision of railway trains.** Julius Ernest Florea and Alexander Olteanu, 45, Southampton-buildings, Chancery-lane, London.

19272. **Improvements in or relating to the steering of electric or steam carriages, cycles, bath chairs, or other like vehicles.** Edwin Ruck Kesterton, 14, Nightingale-lane, Balham, London.

OCTOBER 15.

19275. **Improvements in electric incandescent glow lamps.** Reuben James Bott, 9, Park-place-villas, St. Mary's, Paddington, London.

19304. **Improvements in phosphorescent electric lighting.** William Lloyd Wise, 46, Lincoln's inn-fields, London. (The Moore Electrical Company, United States.) (Complete specification.)

19317. **Electric railways.** John La Burt, 321, High Holborn, London. (Complete specification)

19318. **Improvements in combined telephone and signalling systems.** James Gilmore Smith and Robert Grey Vassar, 52, Chancery-lane, London (Complete specification)

19337. **An improved means for connecting the filament in incandescent lamps with the source of current.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Phönix Süddeutsche Glühlampefabrik Gesellschaft mit beschränkter Haftung, Germany).

19340. **Improvements relating to electric cars.** Percy William Thomas Davies, 31, High Holborn, London.

19353. **Improvements in electric gas-lighting apparatus.** Jean Jahnsson, 323, High Holborn, London.

19374. **Improvements in incandescent electric lamps and the method of making the same** Samuel Edward Cox, 18, Buckingham-street, Strand, London. (Complete specification.)

OCTOBER 16.

19380. **Improvements in the manufacture of insulated cables.** George Hinde Nisbett, 8, Quality-court, Chancery-lane, London. (Complete specification)

19389. **Improvements in tempering the wire points of textile cards electrically, and in apparatus therefor.** Charles Brooke Crawshaw and Rankin Kennedy, Hubert-street, Leeds-road, Bradford.

19402. **Improvements in and connected with return circuits for electric railways and tramways.** William Edwin Hayes, 70, Market-street, Manchester. (Gisbert Kapp, Germany.)

19442. **An improved method of and apparatus for welding by electricity and for other purposes.** Albert Hirsch, 53, Chancery-lane, London.

19461. **Improvements in thermo-electric generators.** Harry Barringer Cox, 46, Lincoln's-inn-fields, London. (Complete specification.)

OCTOBER 17.

19503. **Improvements in telephonic apparatus.** Charles Adams-Randall, 1, The Avenue, Bedford-park, London.

19509. **Improvements in alternating electric current transformers.** John Alexander McMullen, 124, Chancery-lane, London.

19527. **Improvements in high-insulation fuses or cut-outs for electric lighting.** John Mackenzie Urquhart and William Henry Dingle, 23, Bucklersbury, London.

OCTOBER 18.

19551. **An improvement in conduits for conductors of electricity or other mains.** William Douglas Reid, 25, Criffel-avenue, Streatham-hill, London.

19577. **Improvements in incandescent electric lampholders.** Parker Lindsay and John Bradin, 70, Wellington-street, Glasgow.

19605. **Improvements in and connected with dynamos and the driving of same and electric motors for the driving of vehicles and machinery.** John Vaughan Sherrin, 77, Chancery-lane, London.

OCTOBER 19.

19647. **Improvements in secondary batteries.** William Henry Willatt, 22, Jalland-street, Holderness-road, Hull.

19669. **Improvements in secondary battery plates.** Alexander Schanschieff, 77, Chancery-lane, London.

19670. **Improvements in secondary batteries.** Alexander Schanschieff 77, Chancery-lane, London.

19696 **Improvement in electric light display systems.** Jonathan Edwards Woodbridge, 33, Chancery-lane, London. (Date applied for under Patents, etc., Act. 1883, Sec. 103, July 8, 1895, being date of application in United States.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1894.

12483. **Electric batteries.** Shrewsbury and others.
18328 **Telegraphy.** Fletcher.
19184. **Electric heaters.** Davis.
19220 **Electric ship logs, etc.** Whyte and Muirhead.
22819. **Lock and block electric apparatus for railways.** Tyer.
22973. **Storage batteries.** Brown.

1895.

7782 **Electric resistances.** Voigt and Haeffner.
12329. **Telegraphic systems** Merrel and Duffek.
13405 **Electric telephone systems** Marr.
14492. **Electric lamps.** Prieto.
15365. **Electric switches** Dingle and Urquhart.
15513 **Dynamo-electric machines.** Doney.
15886. **Electric batteries.** Wollaston.
16008. **Telephonic instrument.** Dillberg and Rabbidge.

NOTES.

The Tesla Polyphase Patents.—The General Electric Company has been granted more time—viz., until November 16—to file evidence in the suit of the Westinghouse Company against it for infringement of the Tesla patents; and the plaintiffs have 20 days thereafter for cross-examination. The original limit was October 7.

Electrotherapy in France.—The Municipality of Paris having granted 20,000f. for the purpose, new buildings are to be erected at the Salpétrière Hospital for the treatment of nervous and mental affections by electricity, the ward in which the late Dr. Charcot applied the treatment being inadequate for the number of patients.

"Superseding Telegraphy."—The latest Yankee crank is a Mr. Hawkins, said to be a well-known banker and amateur scientist, who proposes to supersede the Transatlantic telegraph "by using the moon as a sort of reflector, and sending an intermittent beam of light from a powerful mirror to the dark surface of the moon, which will then be seen from the other side of the earth." "Fears" are expressed that it may be difficult to make the mirrors large enough!

Electric Carriages on the Stage.—We had the pleasure of seeing yesterday, just before going to press, a four-seated electric carriage, apparently on the Jeantaud system, which Sir Augustus Harris, we are informed, purposes introducing on the stage in his forthcoming pantomime of "Cinderella." As an anachronism, Cinderella in an electric carriage reminds one of the electric incandescent lamps which illumined Jonah's parlour in the whale's interior, as shown in a New York drama.

Electricity at the Brussels University.—The electrical and anatomical institutes founded by M. Ernest Solvay and presented by him and other donors to the University of Brussels have been officially inaugurated under the presidency of the Burgomaster, assisted by M. Graux, the Chancellor, and the entire body of professors. Delegations from the English and Continental universities responded to the invitation of the Brussels University to take part in the series of *fêtes* organised in celebration of the event.

Electrical Conductivity near the Critical Temperature.—Signor Adolfo Bartoli has repeated and confirmed his earlier observations on the electrical conductivity of liquids and gases near the critical temperature, using slightly modified apparatus. Pure benzene has no conductivity either in the liquid or gaseous state—that is, just below and just above the critical temperature. Methylic alcohol and sulphurous anhydride, however, conduct slightly when liquid just below the critical temperature, but lose this feeble conductivity when gaseous just above that temperature.

Peculiar Electric Lamp.—Dr. Aron has devised a peculiar electric lamp which is very useful for special optical experiments. The current is taken between two quantities of mercury, each in one limb of an inverted U-tube, exhausted of air, and the lamp is started by sloping it until there is for a moment a continuity between the two quantities of mercury. Thereafter, the discharge is continuous, and the light produced is of an intense greenish white, but its spectrum is limited to a very few lines, those of mercury, and this enables optical measurements to be effected with great accuracy.

Water Power in Wales.—In the current number of the *Geninen*, the national Welsh quarterly, Mr. Benjamin Davies, of University College, Liverpool, has an interesting article on water power in Wales, in which he comments upon the extravagance of wasting such mechanical power. Were the people, he says, to get the land under their own control, much could be done straight away. "Groups of farmers might join in placing a dynamo electric machine at the riverside, which would supply them at their respective farms, free of cost, with an unlimited supply of power for threshing, winnowing, driving creameries, etc."

The Physical Society.—An ordinary meeting of the Physical Society was held on October 25, Mr. Walter Baily, vice-president, in the chair. Prof. J. Perry read a paper by himself and Mr. H. F. Hunt on "A Method for the Development of Arbitrary Functions," which is an improvement on that described by him during the discussion of Prof. Henrici's paper of April 13 last. Only a planimeter and pencil and paper were required. Mr. F. W. Lanchester read a paper on the "Radial Cursor,' which is a new addition to the slide rule, enabling fractional indices to be dealt with, and which would be useful in problems involving, for example, the adiabatic expansion of a gas.

Lighting by Luminescence.—In a paper read by M. A. Witz before the Académie des Sciences, the author gives the results of his attempts to measure the quantity of energy necessary to illuminate Geissler tubes. The figures that he has obtained show that in lighting by luminescence the proportion of calorific energy as compared with the total energy is feebler than in any other luminous source. The author thinks that by reducing the losses of electricity to a minimum, by concentrating the light in a confined space, by utilising the fluorescence of certain substances, and, finally, by devising certain special arrangements, one may hope to obtain luminous sources whose photogenic rendering will be superior to the best now known.

The Institute of France.—At the centenary banquet of the Institute of France the other evening, Lord Kelvin, after reading an address of good wishes from the Royal Society of London, spoke of the honour which he felt in being an associate, and of the still greater debt which he owed to France as the true *alma mater* of his scientific youth, the inspirer of that admiration for the beauty of science which had made him its lifelong servant. Laplace initiated him in the *mécanique céleste*, and a little later the venerable Biot, taking him by the hand, placed him in Regnault's laboratory. He was ever grateful to Regnault and Liouville for their thorough teaching in 1845 in experimental and mathematical physics. Dr. Frankland then proposed the toast of "France," and many telegrams of congratulation were read from foreign bodies, including the St. Petersburg Academy of Sciences.

The Berlin Exhibition of 1896.—The executive of the forthcoming industrial exhibition in Berlin have come to an extraordinary decision. They have resolved that the exhibition buildings proper should only be opened while daylight lasted, this decision being based on grounds of economy. It was estimated that the electric lighting of the buildings would entail an extra expenditure of 400,000 marks (£20,000), and the majority of the committee were of opinion that for this and other minor reasons the lighting should be dispensed with. On the other hand, it was argued that the increased number of visitors would counterbalance this expense. It must be remembered, moreover, that the restaurants and other buildings in the grounds of the exhibition are to remain open until midnight. The resolution is meeting with considerable opposition, and it is not improbable that it may yet be rescinded.

Electricity and Sprinting.—In running sprint races it is very important to save even the fifth of a second. It has been proved by experiment that the time which elapses between the firing of the starter's pistol and the actual starting of the runner is long enough to influence the winning of a race. An arrangement for measuring a runner's reaction time down to the thousandth of a second has, it is said, been contrived in the Yale laboratory. The starter's pistol is arranged so that an electric contact is broken when the pistol goes off. A thread is attached to the right foot of the runner. This thread breaks an electric contact the moment the runner starts. Each of these electric contacts makes a spark on a smoked cylinder in such a way that the time which has elapsed between the first contact and the second can be measured.

Angling by Electric Light.—Last Saturday night two anglers, one a resident of Newhaven, tried the interesting experiment of fishing in Seaford Bay by electric light. A fisherman of Newhaven rowed the anglers from the Railway Pier soon after six o'clock, when it was completely dark. A portable battery with a 5-c.p. incandescent lamp was taken, and this lamp was lowered until a weight below it touched the bottom at 25ft. Both battery and lamp were specially made for the trial, and the lamp was protected by a galvanised crinoline and was made watertight. When it reached the bottom of the sea there was, it is stated, a circular area, 20 yards in diameter, brightly illuminated right up to the surface. Fishing was carried on with an ordinary line on the port side, the lamp having been lowered on the starboard side of the boat. A successful result followed the experiment, and a splendid dish of whiting was caught.

The Application of the Alternating Current to Railway Work.—An American contemporary says: "We have already chronicled a number of instances of the application of the three-phase system to the covering of long railway lines. It is evidently now only a question of time when the alternating current will be applied directly to the motor on the car. That the large manufacturing companies are alive to the situation is evidenced by the experiments in this direction which we are informed are now being actively prosecuted, and we know that a direct application of the alternating motor to a road about to be equipped is seriously under consideration by its engineers. To be sure, the two wires required for its overhead work will militate against the introduction of the alternating system in cities, but for interurban roads which are now rapidly increasing, and which are practically free from the danger of crosses from overhead wires, there appears to be no valid objection to the use of two wires.

Electricity at the Brighton Carnival.—Not the least interesting feature in connection with the recent carnival at Brighton, a correspondent writes, was the use of the electric searchlight from the top of the great chimney shaft now in course of erection at the Corporation electricity generating station in North-road. Mr. Wright, the superintendent of the works, had caused two very powerful lights to be fixed on the summit of the new shaft, which is 200ft. high. It was estimated that the light was of nearly a million candle-power, and that it could be seen 60 miles off. The current was conveyed to the lights by wires from the generating station. Members of the electrical staff manipulated the apparatus, which was lent specially for the occasion by Messrs. Crompton and Co. and Messrs. Johnson and Phillips. When the light was first turned, on the atmosphere was somewhat hazy, but it afterwards became clearer, and the brilliant light was alternately thrown over various parts of the town, and aroused the interest and admiration of the thousands who thronged the streets.

The Pacific Cable Scheme.—At the invitation of Sir Charles Tupper, a meeting was held at the office of the High Commissioner for Canada on Tuesday to discuss the Pacific cable scheme. In addition to the High Commissioner for Canada, there were present the representatives of the Australasian and South African Colonies. The instructions sent by the various Colonial Governments to their representatives were discussed, in view of the probable forthcoming conference with the Secretary of State. It is announced that the Colonies, being quite prepared substantially to support the scheme, are desirous that the question should no longer remain in abeyance. The question of a fast Transatlantic service will not be discussed for the moment, but the negotiations bear more directly upon the cable scheme proper. It is added that the reported granting of a concession for an exclusive American cable between the United States and the Hawaiian group will probably necessitate the landing of the British cable on another Pacific island at a higher cost. The date of the conference with Mr. Chamberlain will not be fixed until the return to London of the Secretary of State.

Electrical Progress in Australia.—The Chief Railway Commissioner of New South Wales has furnished a number of interesting details in connection with the improvements which the Railway Commissioners are desirous of introducing into the Sydney tramway system. What strongly impressed him in his recent tour in Europe, he says, was the great development of electricity for tramway purposes. The overhead system was almost universally adopted, engineers having divested it of most of the objectionable features which had previously tended to disfigure the streets. As the outcome of the congested state of the traffic in Elizabeth-street, which is the sole artery for all the tram lines radiating from the city, the Commissioners will approach the Government with the view to securing authority for the construction of tram lines along Pitt and George streets. The motive power will in all probability be supplied by electricity applied on the conduit system in the busier portion of the streets, and, beyond such limits, on the overhead system. Ultimately, the Commissioners hope to be able to entirely supersede steam by electricity on the whole of the tramways, as it is thoroughly efficient, and will in their opinion answer admirably for sharp curves and steep gradients, which occur within the metropolitan areas served by the tramways.

Indiarubber.—As supplementing the note under this head which appeared in our last issue (p. 468), we note that the *Kew Bulletin* of miscellaneous information for the month of October gives some details concerning the new rubber industry in Lagos. It states that there was started at the Gold Coast by Sir Alfred Moloney in 1882 a rubber industry, which by 1893 had attained to the annual value of £200,000. In 1882 Sir Alfred Moloney addressed a letter to the *Lagos Times* strongly recommending attention to the possibilities of a similar industry in Lagos, and suggesting "the adoption of measures having for their object the addition of one more to the industries of the colony." The result of this letter was not immediately apparent; but in 1894 the present Governor of Lagos, Sir Gilbert T. Carter, announced that he had been able to induce a party of natives from the Gold Coast experienced in rubber collecting to go to Lagos with a view to the development of this valuable and important industry. A trade in rubber was thus established at Lagos, and a table is appended showing that the industry underwent a remarkable development during the first six months of the present year, the amount of rubber exported rising from 21,131lb, of the value of £1,213. 10s. 3d., in January to 268,619lb., of the value of

Digitized by Google

£12,577. 2s. 6d., in June, the total for the six months being 588,633lb., of the value of £29,765. 18s. 5d. The *Bulletin* adds: "The history of this new rubber industry in Lagos is full of interest, and illustrates the wonderfully rich resources of the vast forests of West Africa. It shows also very clearly how largely these resources can be developed by judicious and intelligent action on the part of the Government."

The Development of Electric Traction.—The developments of the year in electric traction circles, the *Electrical Review* of New York says, have been very gratifying to all connected with the street railway business, and the future is full of promise. For these reasons, as well as others, the annual meeting of the American Street Railway Association, which is in session this week at Montreal, should be a very successful one. Great strides have been made during the past few months in adapting the electric motor to various conditions and requirements of passenger traffic. We have seen old and conservative steam railways forced to give in to the competition of trolley roads, and in self-defence adopt electrical equipment for short local lines. The electrical installations on the Nantasket Beach line of the New York, New Haven, and Hartford Railroad, and the Mount Holly branch of the Pennsylvania Railroad have been proved to be successful, and a new era in combined steam and electric railroading is inaugurated. The big electric locomotive in the Baltimore and Ohio Railroad's belt line tunnel at Baltimore has amply demonstrated its ability to outclass any steam locomotive as a traction motor for the purposes and conditions it was designed to fulfil. The underground trolley lines on Lenox-avenue in New York City, and in Washington, D.C., have been perfectly successful up to date, and bid fair to supersede the cable railway almost entirely. We are promised an electric storage battery surface line in New York City, of which great things are expected. The new cable lines in New York have taken away so much of the traffic of the elevated railways as to oblige this unaccommodating corporation to follow in the footsteps of other steam roads and adopt an electrical equipment, or else be forced to the wall. Besides all these good things, the journal adds, electric railway apparatus has been steadily improved, as have also methods of operation and management.

The Progress of Electricity in Canada.—Mr. George Johnson, the statistician of the Dominion Government, has published some interesting data regarding the progress and present status of the electric railways, telegraphs, etc., of Canada. The present value of the electric railways, telegraphs, etc., of the Dominion is given by Mr. Johnson as follows:

Telegraphs and cables	$7,000,000
Railways	13,000,000
Telephones	1,000,000
Electric light works	6,000,000
	$27,000,000

The first cable laid in Canada was between Prince Edward Island and the mainland, and was put down in 1852. The cable between Cape Breton and Newfoundland was laid in 1856. The telephones of Canada have 44,000 miles of wire and 35,000 instruments. The Dominion Government own 238 miles of telegraph cable line, the total mileage of their land lines being 2,500. There were in 1891 80 electric light works in Canada, with a capital of 4,113,771dol., employing 763 hands, and paying annual wages of 297,700dol. The annual value of output was 1,154,150dol. The previous census of 1881 showed only two hands as being employed in electric works. There were at the end of 1894 368 miles of electric railway in Canada, making 73 miles to each million of people. There were 658 motor cars, 341 trailers, 39 snow-sweepers, and 891 motors. In 1894 the number of miles run was 15,587,226, and the passengers carried 55,348,612. The different electric railway companies had 2,614 employés and a paid-up capital of 13,035,263dol. In 1893 there were only 256 miles of electric railway, the increase for the year being 112 miles. Every province now has electric railways except Prince Edward Island. To show the progress and present position of electric railways in Canada, as compared with other countries, the following table is given:

	Miles in operation.	Cars.
Europe	434	1,236
Germany	227	632
France	60	152
Austria-Hungary	28	129

The steam railways of Canada carried in 1894 14,500,000 passengers, or only about one-fourth of the number of the electric railways. If the patronage of electric roads had been equally distributed, each person in Canada would have been carried 12 times by electricity.

The Blackening of Incandescent Lamps.—Signor G. Tolomei has recently published an article wherein he gives the result of the microscopic examination which he made of filaments of incandescent lamps, before and after use. By the same means he also studied the pellicle deposited upon the glass. The instrument employed by the experimenter magnified 850 times. A filament not yet used presents a regularly undulating surface; on the other hand, the filament of a lamp out of use is covered with minute protuberances resembling in miniature those of arc carbons. The protuberances appear to have been produced by molten matter. Near the points of rupture and often elsewhere the filament seems to the naked eye to be covered with lampblack; in these places, and especially near the rupture, it appears, under the microscope, furrowed with transverse cavities, like craters, from which spring ramifications of lampblack, which have the appearance of volcanic jets. The examination of a pellicle of a blackened globe shows that the deposit is much thicker opposite the point of rupture than elsewhere. This, according to the author, indicates that the cause of the rupture is the same as that which produces the blackening of the glass, and that it is in relation to the development of a gas proceeding from the filament. The theory according to which the blackening would result from a chemical change of charcoal by an oxide of residuum would not thus be correct. The hypothesis that a sublimation of the carbon is produced, like that obtained by Moissan with the electric arc, could also not be sustained, for such a phenomenon would not give place to the ramifications just referred to. From his observations Signor Tolomei concludes that the destruction of the filaments is effected approximately as follows: Certain mineral bodies contained in the filament are melted by the high temperature, and in consequence of their evaporation the carbon undergoes a progressive disintegration; certain very minute particles of carbon are thrown upon the glass. When the explosions of the minute protuberances of the surface are violently produced, whole fragments are detached, and it is in the places whence these fragments are detached that most frequently the rupture of the filament finally happens. This explanation is not entirely satisfactory. Very fine filaments, richly nourished by the carburation (the carbon thus deposited containing no mineral substance), decompose and blacken the globes, as also those which have been feebly nourished. Besides, the degree of the blackening of the lamps and the durability of the filaments depend very largely upon the carburation of the latter, facts which are difficult to explain by Tolomei's theory.

The Indian Telegraph Department.—In its annual review of the working of the Telegraph Department during the year 1894-95, the Government of India gives expression to the opinion that the working of the department is highly creditable to the Director-General and the staff of the department. The past year's report shows that the department's reputation for successful and economical working is fully maintained. During the year, 1,941 miles of line, involving 4,000 miles of wire, were added to its already enormous charge, the total being now 44,648 miles of line, requiring a length of 138,256 miles of wire, and representing a capital outlay sunk in the operations of the department of no less than 574 lakhs of rupees. The department is seemingly as successful in its financial affairs as it is in executive matters, for the revenue returns show a balance on the right side. The gross receipts amounted to 80 lakhs of rupees, against a total expenditure of 57 lakhs, leaving 23 lakhs as the net receipts. This would have been better by 4½ lakhs but for a special rebate to that amount made to the East Indian Railway for rent charges for seven years ended with 1893. The report is simply a record of continued improvement throughout. Private traffic exhibits rapid progress, an increase of 218,982 having taken place in the number of messages sent over the wires. State inland messages decreased in number, but increased in value, this being accounted for by the recent military operations in Chitral. On the whole, the net revenue receipts for the year are equivalent to a return of a little short of 4 per cent. on the capital outlay. The actual messages sent over the wires during the year were 3,200,000, or an increase of no less than 1,700,000; the increase during the last 10 years has been 111 per cent. in number and over 96 per cent. in value. The speed of transmission has also been fully maintained. Over the whole length of line and the area covered by it only a little over 2,000 interruptions had to be recorded, while the number of complaints entered is an insignificant 1,500. Readers will remember the arduous task so successfully carried out in the Srinagar-Astor connection over the inhospitable Himalayan mountain passes; and, again, the work on the Bhamo-Momein frontier, which gave India overland telegraphic communication with China. Both these works are well in the front rank of telegraphic history, and deservedly so. Very few outside the circle of those who have had the work to do, the *Indian Engineer* remarks, can ever thoroughly estimate the nature of the operations and conditions of labour, self-sacrifice, and danger which such projects involve, and their successful completion in the face of all the difficulties met proves the Indian Telegraph Department to be second to none throughout the globe.

The Comparative Efficiency of Driving Ropes and Belts.—Prof. D. S. Capper read at the last meeting of the Institution of Mechanical Engineers a paper embodying a translation of the "Report on the Lille Experiments upon the Comparative Efficiency of Ropes and Belts for the Transmission of Power," and his observations thereon. The author remarked that in almost all these experiments the chief object has been to determine the limit of load under ordinary working conditions, beyond which a belt will slip upon its pulley. The work of Morin left out of account the effect of speed of slip upon the frictional coefficient; and although Messrs. Briggs and Towne recognised its influence, they were unable to carry out experiments of a satisfactory kind at the speeds of slip due to the elasticity of belts under ordinary working conditions. Other experimenters, working at lower speeds of slip, obtained conflicting results; and it was not until 1882, when Prof. Holman experimented at varying speeds of slip with the express object of finding the cause of the discrepancies, that the coefficient was known to vary from 0·58—the value obtained by Morin and Mr. Towne—down to 0·12, when the speed of slip was sufficiently reduced. Since then Prof. Lanza has set all doubt at rest by a careful and elaborate series of tests, in which the average speed of slip under ordinary conditions has been determined, and the value of the coefficient of friction for that speed found to be 0·27, a value which Mr. Towne accepts as more accurate than that which he was forced to deduce without direct confirmation. It is therefore possible to ensure that no excessive loss shall occur from slip. But there still remain residual losses—slip due to elasticity, work in overcoming the stiffness of belts, reduction of the coefficient at high speeds by centrifugal action and by air—about which very little is definitely known. The experiments of Mr. Lewis and M. Leloutre tend to show that the total loss in well-designed belt gearing does not exceed 3 or 4 per cent. of the gross power transmitted, and M. Fauquier has investigated the losses due to stiffness, with results which require confirmation before they can be deemed conclusive, and with which the observations of Mr. Lewis directly conflict. By the Lille trials it has been shown that ropes are practically as efficient as belts, though some slight doubt has been cast upon the actual value as previously determined of the losses in belt gearing, from the fact that the variation which was found between individual observations at Lille exceeded 3 per cent. It is to be regretted, Prof. Capper added in conclusion, that it was not found possible with such a unique installation to extend the limits of the research; but it must be admitted that the difficulties were great, and the increase in the outlay would probably have been large.

The Catteri Electric Railway.—It is perhaps well that Dr. Albert Battandier thinks highly of the method of working electric railways devised by Captain Cattori, in order that the inventor may be spurred to further efforts, as the present attempt will find few other supporters. The learned doctor says that we are to owe to Italy the removal of the last obstacle in the way of the employment of electric traction on railways. In the Cattori system the current is conveyed to and from the car by the rails, the return wire for each section of the line being laid by the side of the track. The one rail is thus used as lead and the other as return. It follows that the rails must be insulated from each other, and the wheels must also be insulated from the axle. Calling the rails A and B, when a car enters the section the current goes by the rail B up to the car, from rail B through the car motor to rail A, and thence in front of the car along rail A to the return wire. The line is single, and naturally there is some complication at passing-places, but an arrangement for these has been worked out. The insulation of the wheels is effected by a hub of *lignum vitæ*, or, we are informed, "if hardened paper wheels with iron or steel tires are used, as in America," perfect insulation is obtained without further trouble. Contact brushes and wires take the current from tires to the motor. The rails are above the ground, not level with it, and continuity is secured between them by copper connections, the ends of which are driven into holes drilled into the rails, or one of the holes of the fishplate is used. There is nothing to fear from rain, we are told, since water flows off the line to the ballast, and snow can be dealt with by a sweeper car. Moreover, a heavy current and a low voltage can be used. To test the system, an experimental track about 700 yards long has been constructed with rough ballast and old railway

Digitized by Google

sleepers. The rails were spiked down with spikes which were too long and passed through the sleepers, so that their points protruded. Dr. Battandier considers that as in spite of this the cars ran, "it must be confessed that the Cattori system triumphed over all difficulties." It would be interesting to learn what proportion of the total current supplied to the line was used in the motor when the ballast was damp, and what proportion leaked. It would, perhaps, be as well to determine the amount of the leakage before converting all our railways into Cattori lines, even though, as must be remembered, they would still remain available for steam traction, provided the wheels of the engines and rolling-stock were made non-conducting. We would suggest to the inventor of this most novel system that one advantage has escaped his notice. He should let the ground between the rails to a firm of electroplaters, who would be able to utilise the leakage currents; or, better still, by making a trench down the centre of the track he should manufacture the Hermite solution for deodorising sewage in it.

The Fetish of Public Safety.—A writer in the *Railway Times* comments, under this title, on the Portrush Electric Tramway crisis as follows. He has, of course, not seen Major Cardew's report to the Board of Trade, which we publish on another page: "If for the sake of argument it were admitted that Mr. Walne came by his death through electric shock, we are far from thinking that the circumstance would justify a prohibition of the present system of conducting electricity. Public safety has been made far too much of a fetish in this country. The Regulation of Railways Act has stifled light railway enterprise and deprived outlying agricultural districts of many lines which would have been a boon and a blessing to the struggling farmer. The perennial agitation against level crossings is only another phase of the folly which forgets that cheap and rapid transit is at least as important as immunity from accident. If Mr. Walne had been thrown on his head against a stone wall he would probably have died all the same, but the public would have learned of the sad accident with equanimity and there would have been no agitation for the removal of such dangers from the path of the unwary cyclist. If electric railways like the Giant's Causeway line were as numerous in the United Kingdom as leaves in Vallombrosa the number of fatalities due to electric shock would certainly be far smaller than the number of those due to indecision in crossing the Strand, but no one, so far as we are aware, proposes to do away with the cabs and omnibuses which render life in that thoroughfare so precarious. The Giant's Causeway Electric Railway and Tramway Company have done a very excellent work. It was the pioneer electric line, and it first demonstrated the commercial value of electricity as a motor. The railway has rendered incalculable service to the beautiful district through which it passes. Instead of the 5,000 visitors who went to the Giant's Causeway in 1882, 100,000 people visit it now, and the whole district has derived benefit from the development of the means of transit. In the very nature of the case, goods traffic is conspicuous by its absence, and, with only tourist traffic to rely upon, the company would have been unable to earn the smallest modicum of dividend had it not been possible to utilise the motive power available from the falls of the River Bush, by means of a conducting rail carried cheaply along the roadside. Any new regulation requiring the company to carry this conductor underground, or otherwise protect it, would inflict upon the undertaking fresh capital expenditure which it is ill able to afford, and we trust that the Railway Department of the Board of Trade, recognising the services which have been rendered to the community, will think twice before saddling the company with onerous conditions in the interests of 'a few local owners of cattle,' or even in those of that modern fetish, 'the safety of the public.'"

The New Alkali Process.—The new Castner-Kellner process for the manufacture of caustic alkali and bleaching powder by means of the electric decomposition of salt or alkaline salts has aroused considerable interest in electrochemical circles. Mr. Jas. Hargreaves, of Widnes, writes: The decomposition of salt by electrolysis is a subject at which I have worked more or less as a dilettante from 1875 to 1890. At the latter date the late Mr. Thomas Bird and myself went thoroughly into the matter, Mr. Bird's time and labour being exclusively employed in these researches until the date of his death at the beginning of the present year. As a preliminary we closely examined all accessible data, and all the ideas we could ourselves think of, which included pretty nearly all the ideas covered by the Castner and Kellner patents. In making this remark, I am not in any way hinting that the same ideas did not originate with these gentlemen, or that they have not the most perfect right to secure them by patent. The use of mercury seemed very tempting at first, but we found that it presented difficulties of its own in working. But apart from, and beyond, the question of manufacturing, the physical properties of mercury were carefully considered, in which the researches of Regnault and Merget were of great assistance. At 10deg. C. = 50deg. F., its vapour tension is 0·0268mm.; at 20deg. C. = 68deg. F., 0·0372mm.; at 30deg. C. = 86deg. F., 0·0530mm. Mr. Castner's assertion, that "as the reaction takes place under water there is no escape of mercury," is an error. I should have thought that Prof. Sir Henry Roscoe being on the board of directors, it would not have been necessary to have these facts pointed out. The sodium amalgam is decomposed by contact with water, the oxygen of which is absorbed by the sodium. The hydrogen of the water is strongly occluded by the mercury forming practically an amalgam of hydrogen and mercury, the decomposition of which is due to the very high vapour tension of the hydrogen. This forms one of the difficulties of separating the very small proportion of sodium present in the amalgam after it leaves the anode cell, and ensures that the hydrogen shall be fully saturated with mercury of the tension due to the temperature at which it escapes from the surface of the metal. The question to decide is whether the statements of Mr. Castner, or those of Regnault and Merget, are to be accepted. Anyhow, those who have the facilities may try the experiment for themselves. Into a bottle with water on the bottom, drop from time to time small pieces of mercury amalgam, suspend a strip of gold-leaf in the bottle, and expose it to the hydrogen which escapes from the water. After a time the gold-leaf will be tarnished by the mercury which it extracts from the hydrogen. It must further be borne in mind that the mercury thus deposited is only a very small proportion of the total mercury carried off by the hydrogen. Those who interest themselves in the question will find the researches of Regnault and Merget discussed in *Comptes Rendus*. I do not quite remember the years, but a search through 1870, 1871, and 1872 will find them. After considering the facts, my colleague, without waiting for my opinion, emphatically declined to have anything to do with a business so likely to injure his fellowmen, no matter what profit it might bring. My own feeling was precisely the same, but I have a distinct remembrance of feeling hurt by his emphatic manner, because it seemed to hint that I should have been content to make a profit by such a means. From this Mr. Castner will learn why his patents were not anticipated.

THE ELECTRICAL PLANT AT THE WATERLOO AND CITY RAILWAY.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

This railway, which is to provide the much-needed communication between the Mansion House-circus and Waterloo, is being rapidly constructed by Messrs. J. Mowlem and Co. As described in our issue of March 1, 1895, the line is being excavated on the Greathead shield system, and will eventually be worked electrically. It is seldom, however, that electricity has been so extensively used as an aid to the contractor in executing railway work. Messrs. J. Mowlem and Co. obtained the contract for carrying out the work for the Waterloo and City Railway Company. Having seen from previous experience the possibilities of electric traction, they decided to adopt it to assist in the excavating process, and retained Messrs. Bramwell and Harris to draw up a scheme for their electric lighting and traction work. The general arrangements of the works are worthy of more than the passing notice I am able to give them.

A site in the river by the Surrey shore was chosen, and a stage constructed by piling the river bed. There two circular caissons were sunk down into the clay till the level of the line, some 70ft. down, was nearly reached. The lower end of these iron tubes are supported on brick arches, which form entrances to the tunnels. The excavation of the tunnels could then be commenced with the Greathead shields. The shields used are similar to those which were employed on the City and South London Railway. They are pushed forward by eight hydraulic jacks, pressing against packings which bear on the finished part of the iron tube, and spaced at equal distances round its circumference. By working some of the hydraulic jacks and stopping the others the direction of the shield can be varied as may be desired. An advance heading, strongly timbered, is kept a few feet in front of the shield; and the excavation is done entirely by means of pick and shovel. The soil dug out is loaded at once into skips, which stand on low platform trucks running on rails of 18in. gauge. These skips are coupled together, and the loaded train is hauled to the shaft by electric locomotives. Steam cranes on the staging raise the skips to the surface and empty the soil into barges alongside. It is in this that the position of works are so advantageous. The whole of the transport, both of the excavated material and iron lining, etc., for the tunnel can be effected by water. This greatly facilitates and cheapens operations. The whole of the boilers and machinery for compressing air and for generating electricity are placed on the staging. The consulting engineers, Messrs. Bramwell and Harris, fixed the voltage for lighting purposes at 100 volts, and adopted 200 volts as the pressure for traction purposes. Hence, they arranged that at first two shunt-wound dynamos, each giving 112 amperes at 100 volts, should be used, and should be run in series for driving the locomotives.

The contract for the generators was given to Messrs. Paterson and Cooper. The first machines were each coupled to a 7½ × 7 Robey engine, running at 300 revolutions per minute. A third similar set was added, and then a larger coupled plant was ordered for traction purposes only; this steam generator is capable of giving 145 amperes at 200 volts when running at a speed of 250 revolutions. The engine of this set was made by Messrs. Browett, Lindley, and Co., and the dynamo was also supplied by Messrs. Paterson and Cooper, who have kindly given me the following details of it: The armature is 16½in. diameter and 24in. long, and is Gramme wound. It is a shunt machine, the resistance of the shunt coils being

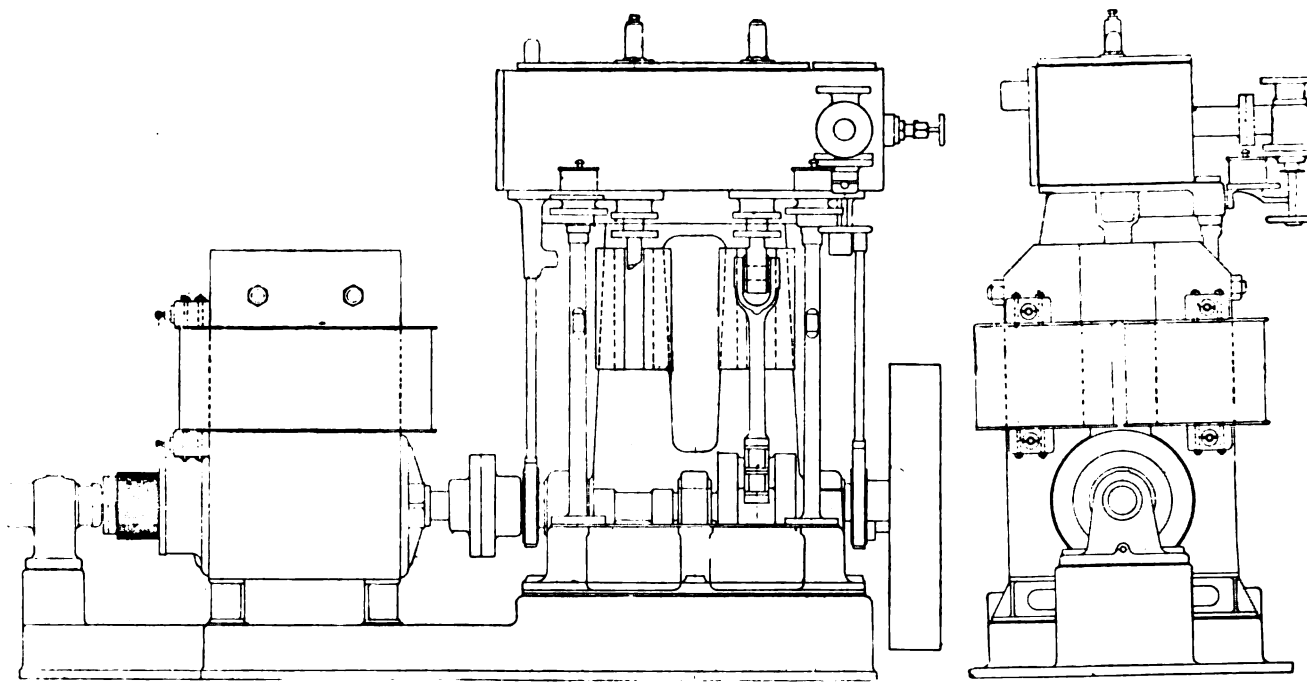

FIG. 1.—The 29 K.W. Paterson and Cooper Dynamo Coupled to Browett-Lindley Engine.

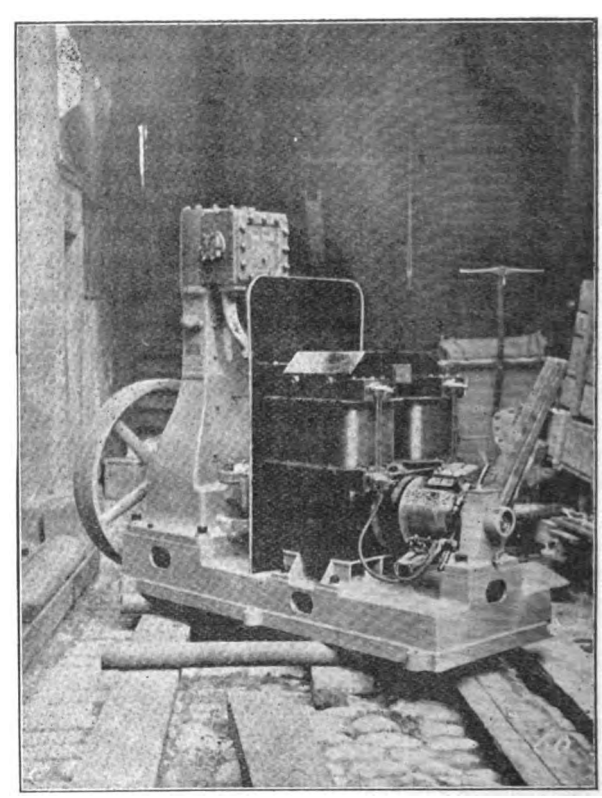

FIG. 1A.—The 11 K.W. Steam Dynamo.

Digitized by Google

41 ohms, and that of the armature ·066 ohm. Fig. 1 shows the construction of this set.

The three smaller machines have each an armature of 12½in. diameter by 14¾in. long, the armature resistance being ·065 ohm. Fig. 1A shows one of these smaller sets before being fixed in position. The crowded state of the engine-room does not permit of a photograph of the steam dynamos in position being taken. Thus on the one end of the stage there are five locomotive boilers—three of which are of 100 h.p. and two of 120 h.p., in a small boiler-shed—two large air-compressors, by Messrs. Markham and Co., and the electric plant above mentioned. It speaks well for the care of Messrs. Mowlem and Co.'s engineer that all this machinery should be working satisfactorily on such a foundation.

The Locomotives.—The design of these has varied considerably, as improvements have been suggested from experience gained in work. The consulting engineers specified that the locomotive should be capable of drawing some five tons on the level at a speed of from six to seven miles per hour, or up a grade of 1 in 60 at a speed of three miles per hour. These requirements have been most amply met by Messrs. Siemens Bros., as on my visit I took the speed of a trip when the load was eight tons, and it averaged 9¼ miles per hour with a grade of 1 in 800. When running light over the same portion of the road, a speed of 12·6 miles per hour was easily obtained. Three locomotives have been supplied by Messrs. Siemens Bros. and Co. up to the present. The first one was started on February 25, and has since run for some 200 days of 24 hours without repair and with only one set of brushes. For 18 hours a day the locomotives work at full pressure. The second locomotive was started on May 4, and has been at work ever since. The third was started on October 1, 1895.

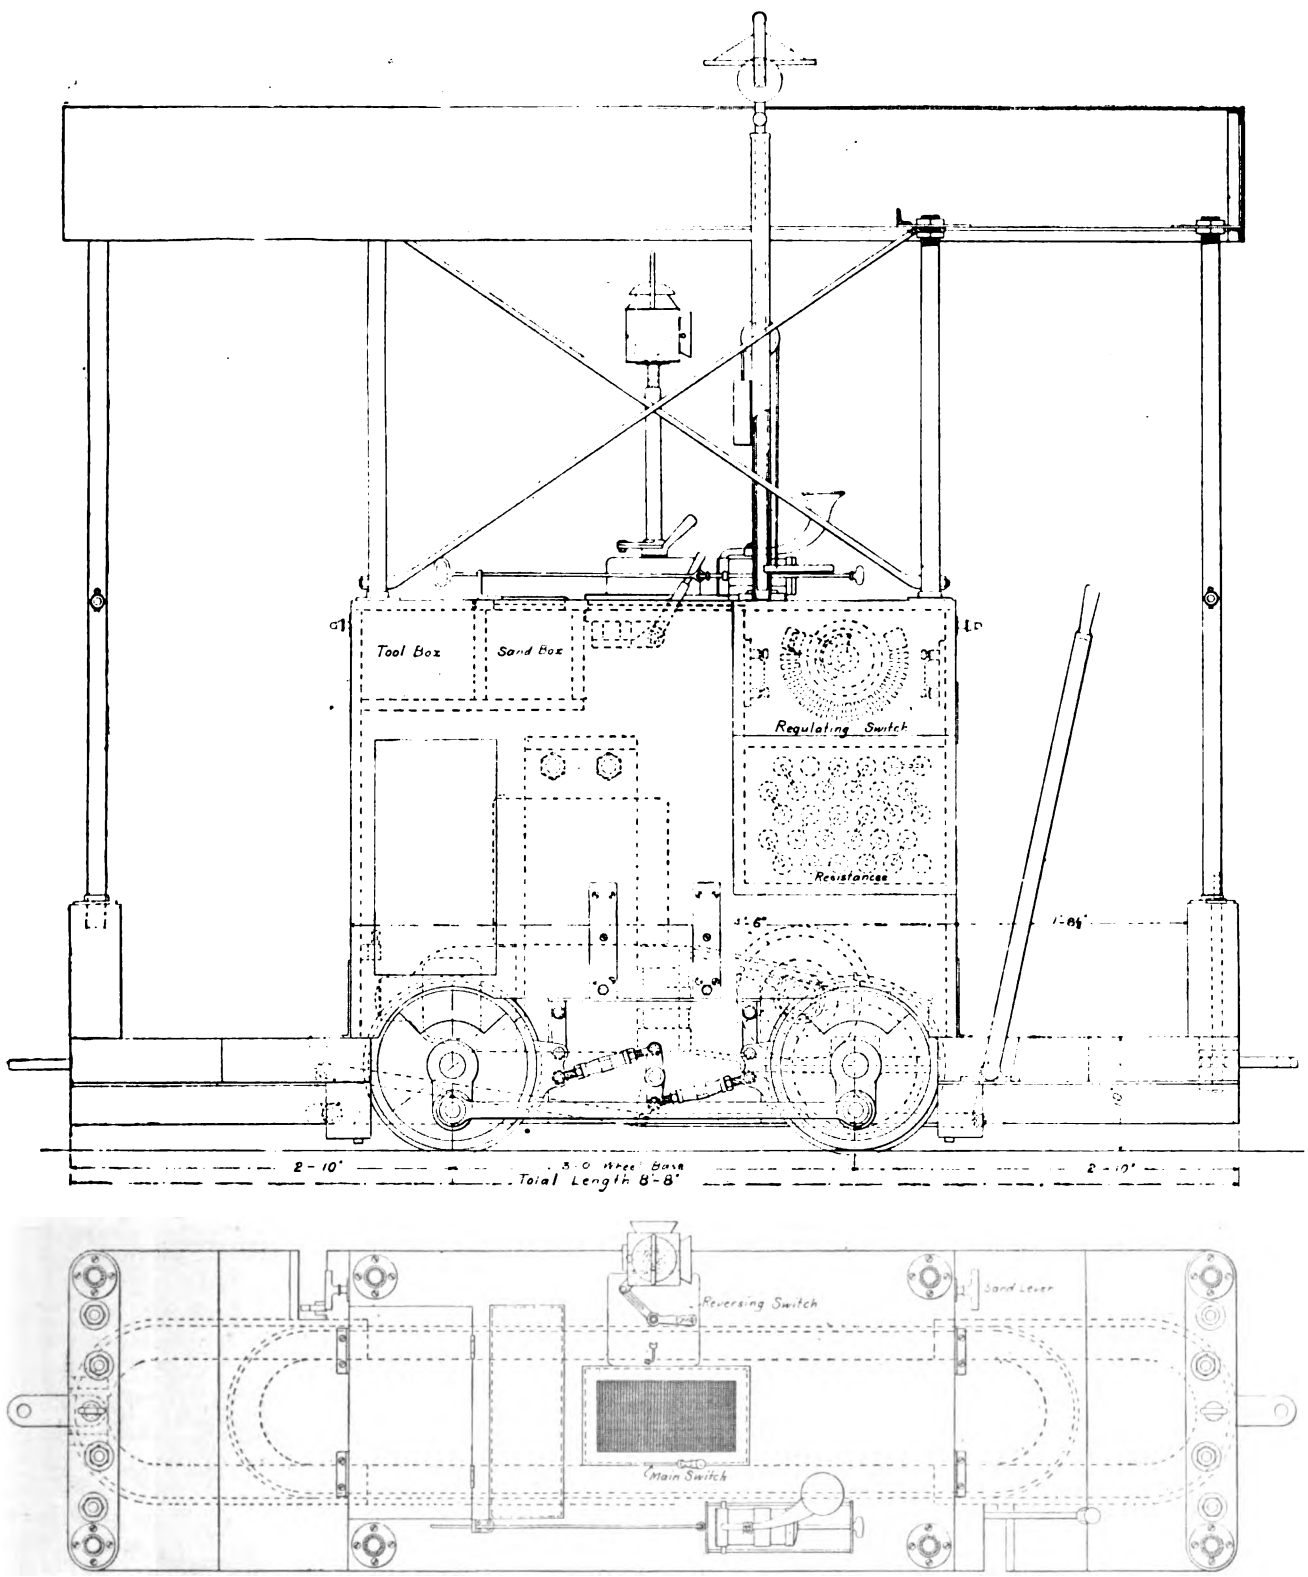

FIG. 2.—The No. 2 Siemens Locomotive.

Digitized by Google

The narrow gauge of the line and the necessity of having one siding at the working face and two under the shaft seriously cramped the design. The actual width available, owing to the circular form of the tunnel, is a little over 10ft., and the width of the locomotive had to be considerably under one-third of this to enable it to safely pass places where skips are standing on the sidings at either side of the centre line of rails. The illustrations (Figs. 2 and 3) show the second of these locomotives, in which the frame was lengthened to give standing room at each end. The motor, which is of the Siemens H.B. 8.10 type, has been most carefully protected against damp. The series coils are surrounded by metal cases, which are hermetically sealed. These can be seen in Fig. 4. The armature is also surrounded by gunmetal castings, handholes covered by slides being provided for the inspection and adjustment of the brushes. The brushes are made of copper gauze, and are placed end on to the commutator. They slide in rectangular guides, and are held against the commutator by springs. The clearance between the brush holder guide and the commutator is barely $\frac{1}{16}$in., so that the brush does not burr over. This construction has worked most satisfactorily, and enables the motor to run in either direction. There is no provision made for varying the lead with the direction of rotation, the brushes being fixed on the centre line. The gearing connecting the motor to the axles is a double-reduction. A bevel pinion of phosphor bronze is keyed on to the armature shaft outside the end bearing, and gears into a bevel wheel of cast iron. A steel pinion on the same shaft as this bevel wheel drives the cast-iron spur wheel on the axle (Fig. 2).

As can be seen from the illustration, the whole of the gear is encased. The spur gearing and bevel gearing run in oil, and when examined after four months' work

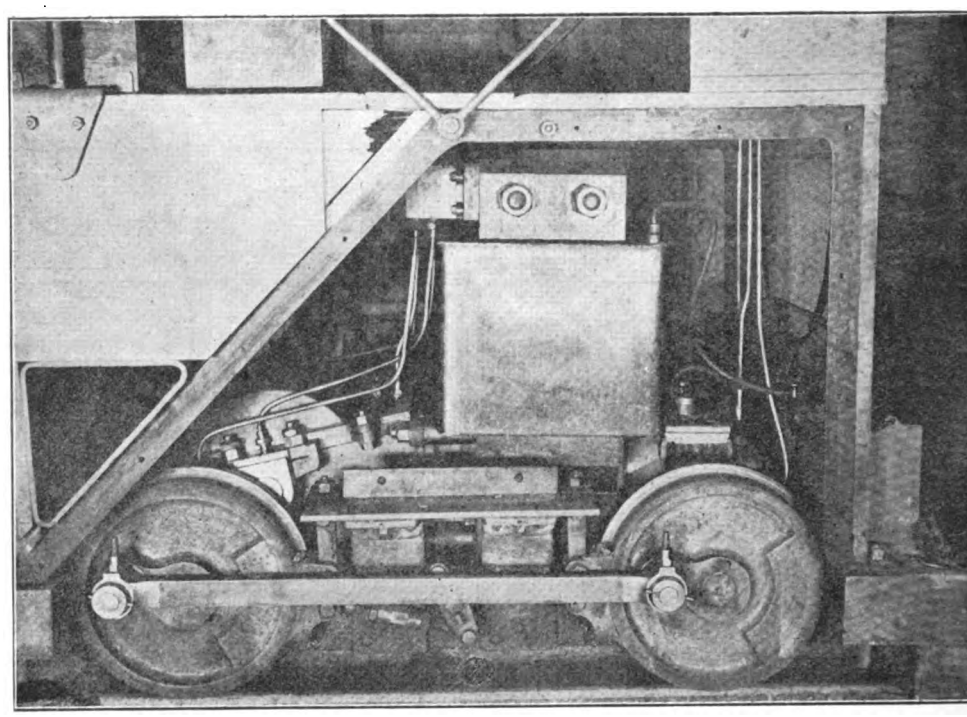

FIG. 4.—View of Locomotive with Cover Removed to show Driving Gear.

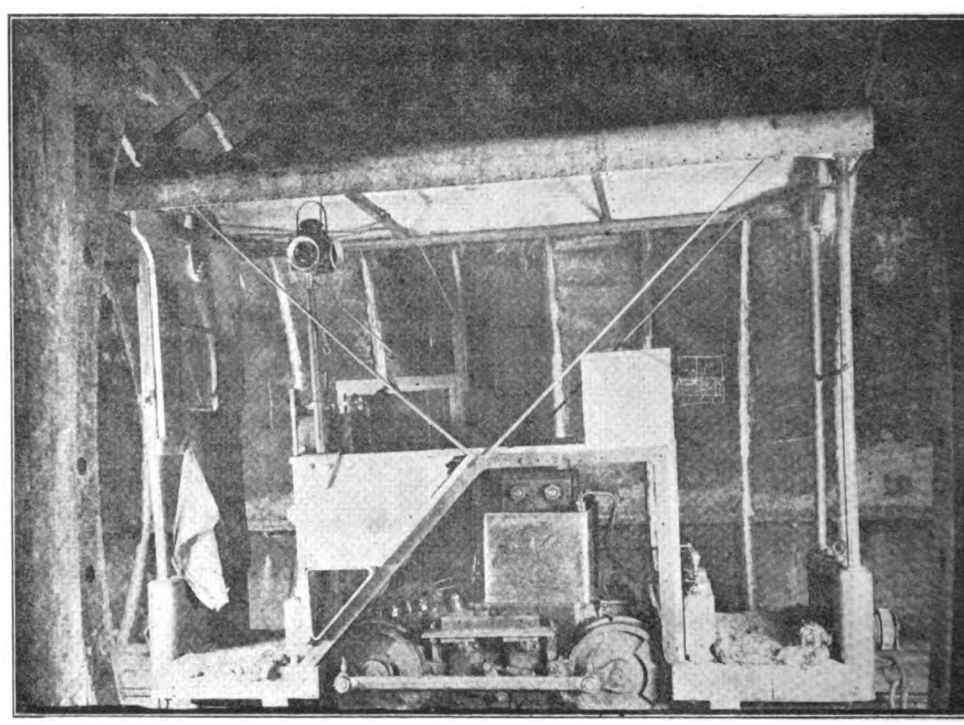

FIG. 5.—Side View of No. 2 Locomotive.

were found to be in perfect order, the surfaces of the teeth being polished and glazed. The wheels of the locomotives are coupled by connecting-rods. In the first design the starting and regulating switches were connected to the brake levers, so that the locomotive could be driven from either end. The forward motion of the brake lever first took the brake off, and then switched the current on. This method has, however, been abandoned, and the brake lever has been replaced in the last locomotive by screw gear, which is more satisfactory. The reversing switch is geared

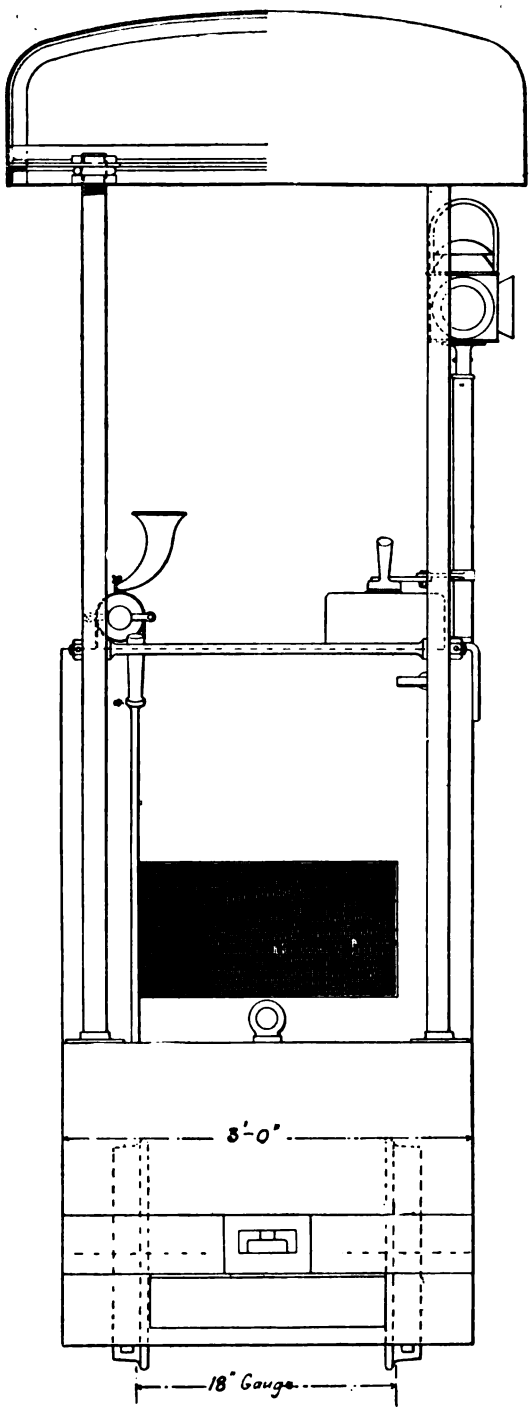

FIG. 3.—End View of Locomotive.

to the red lamp on the locomotive, so that it always turns the light to face in the direction in which the train is moving. The locomotive is strongly built on a wrought-iron frame, and covered in with wooden sides, which can be readily removed for inspection or cleaning. The whole of the canopy and switch gear can be readily removed. The connections from it to the motor are made by means of four plugs and flexible leads, seen in Fig. 4. The regulation of the motor is wholly carried out by means of resistances inserted in the main circuit, the number of series-turns on the field magnet remaining constant. Fig. 6 is another view of the second locomotive, and Fig. 7 shows the alterations effected in the third locomotive, and which have given great satisfaction. The starting switch on this locomotive is placed in full view, and has a glass front. The weight of the locomotive complete is about three tons.

Collecting Gear and Line.—From February to June a two-wire overhead system was used, with a trolley slipper running above the wires. This was on account of the difficulty which it was anticipated would be experienced in reversing the locomotive with the ordinary under-running trolley construction, in consequence of the limited head-room in the tunnel. It was thus decided to use an over-running trolley carriage, hauled by means of a twin flexible cable. This arrangement also permitted of the use of the main line trolley wire at sidings, the "angle of pull" of the cable on the trolley carriage not being sufficient to cause any trouble in this respect. The construction, however, gave trouble when the two wires were not strained equally. Also, as the line required frequent lengthening, the extension caused some difficulty with the two wires, so that finally

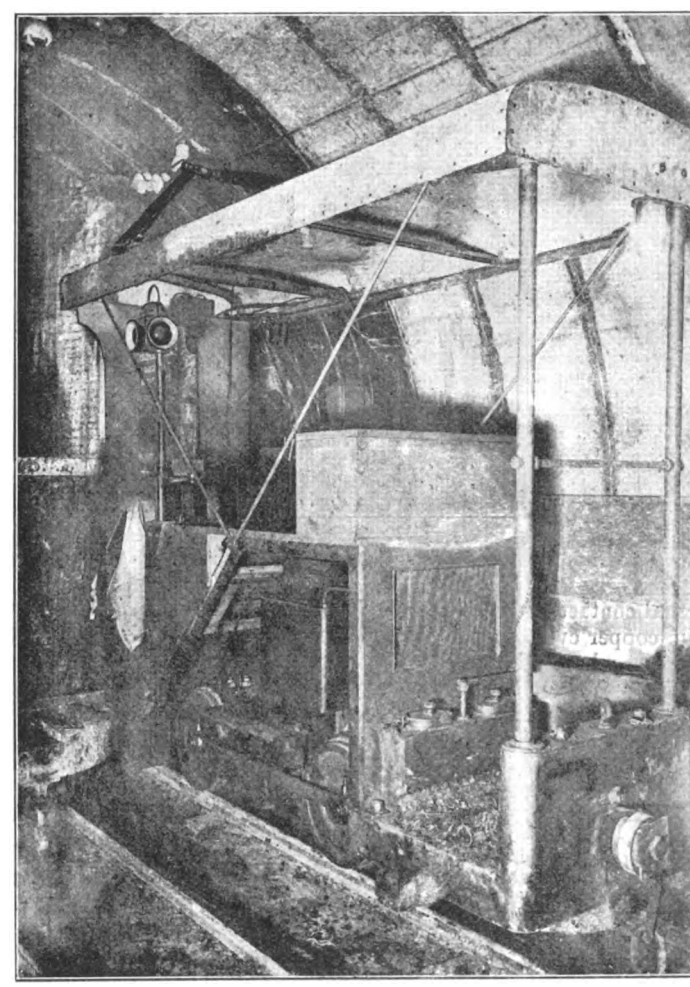

FIG. 6.—End View No. 2 Locomotive

it was decided to abandon the return circuit and to work with an earth return and a single conductor only. When crossing the shaft also trouble was found with the two-wire system, as the conductors do not cross the space. Hence the flexible leads had to be disconnected from the locomotive each time, and those on the other side connected again, before the locomotive could proceed.

With the single-wire system, owing to the limited height available and the dip necessary when going on to the side roads, and also to the fact that time could not be allowed to reverse the lead of collection when reversing direction, there was some difficulty in designing a suitable collector. Another special condition which added to the difficulty was having to cross under the shaft where it was impossible to carry the trolley wire. Mr. H. Allen, the electrical engineer in charge of the work for Messrs. Mowlem and Co., has designed two forms of collectors to comply with these conditions. The first is the telescopic pattern shown diagrammatically on the car in Fig. 2 and in detail in Fig. 8. The vertical pressure of the collector against the wire is maintained by the action

Digitized by Google

of weights, whilst indiarubber springs allow the collector to take a certain amount of lead in whichever way the locomotive is running. The other collector is always inclined at an angle to the wire, but when the locomotive is moving in one direction the angle is against the motion. In this collector, again, the pressure is maintained by weights. The current. The whole of the line material has been also supplied by Messrs. Siemens Bros. and Co.

At present the two tunnels extend about a quarter of a mile in either direction from the shaft. One locomotive is always at use in each tunnel, working somewhat as follows: It draws a batch of empty skips up to the City end of the

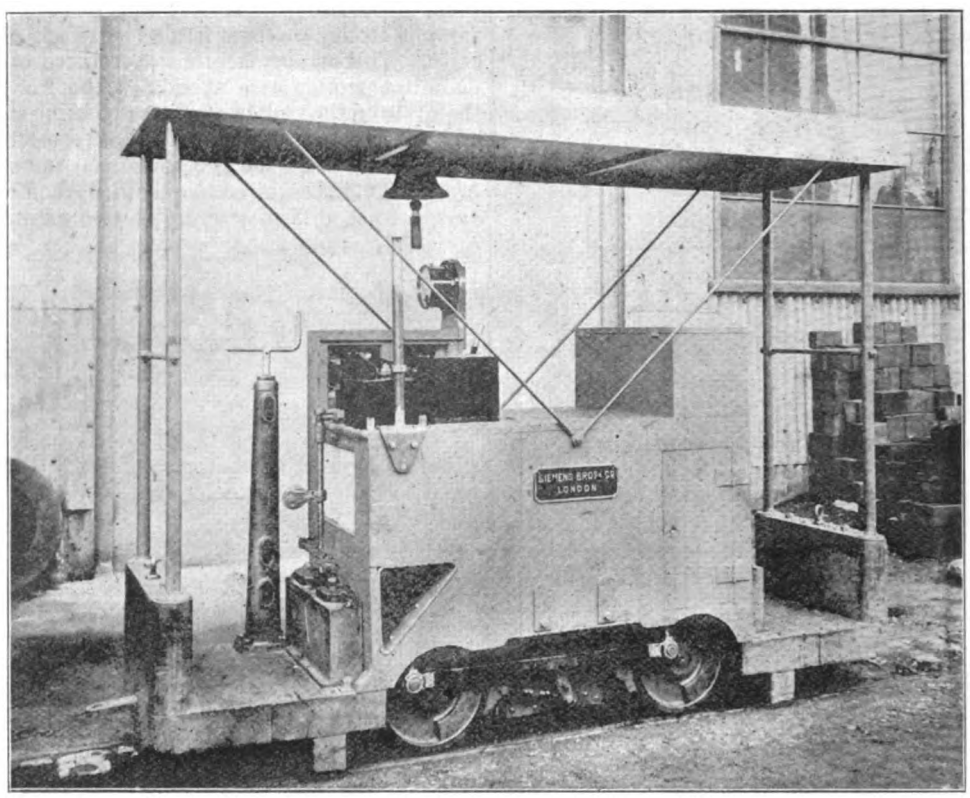

FIG. 7.—View of No. 3 Locomotive.

actual contact with the wire is effected in both cases by a 2in. copper cylinder some 13in. long, which allows ample margin when taking the points. The trolley wire is of 0·25in. diameter hard-drawn copper, held in "ears," which grip it by means of two set screws in such a way as to leave a clear section of wire (Fig. 9). About 1½ miles of this is tunnel and shunts them into one siding there. It then pulls a train of about eight loaded skips to the shaft, and takes another set of empties up to the Waterloo end of the same tunnel. An idea of the frequency of the journeys can be obtained from the load curve taken from the generator on the 28th ult. (Fig. 10). At the Waterloo end of

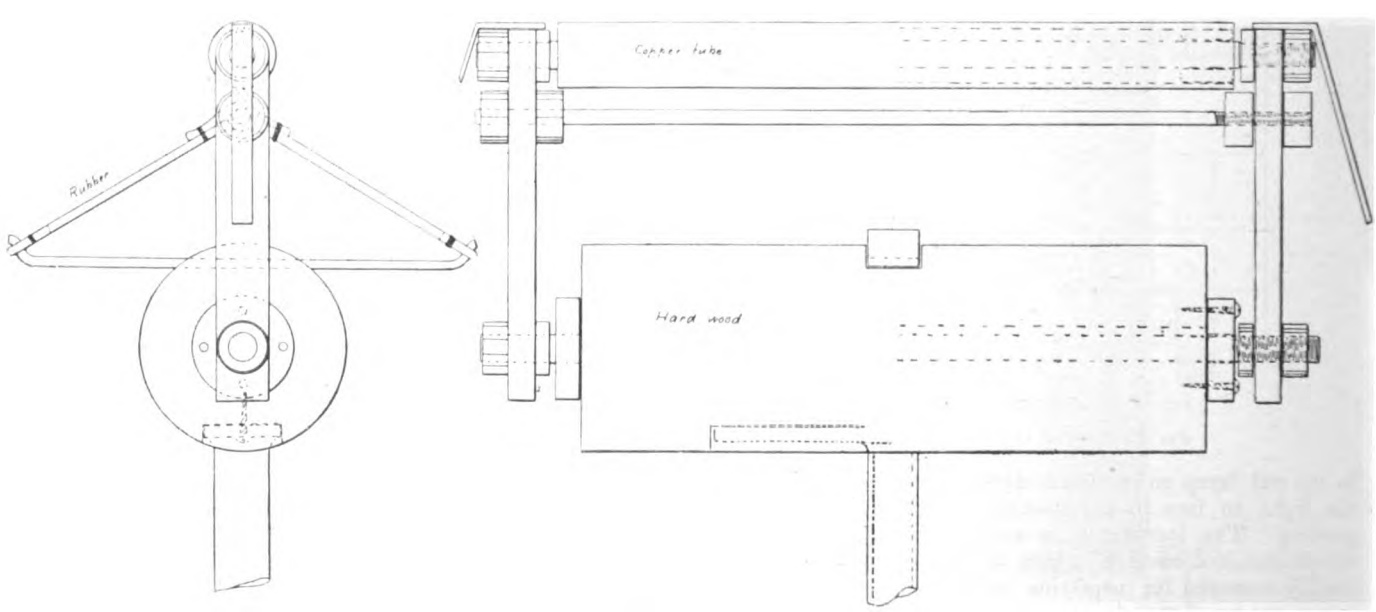

FIG. 8.—Details of Vertical Collecting Gear.

now fixed in the two tunnels. The method of insulating the wire and of attaching it to the iron segments of the tunnel is easily understood from the illustration. The return circuit is made through the rails, which weigh 56lb. to the yard. The rails have no special bonding arrangements, but are connected at intervals to the iron lining of the tunnel, which forms a most efficient return path for the the tunnel gravel has been found, which necessitates the use of compressed air to keep the water out of the workings. Hence air-locks have been inserted, and a pressure of about 32lb. absolute is maintained beyond them. The locomotive works up to the air-lock, but on the pressure side the skips are pushed by hand.

At both the compressed-air faces the Greathead shield

Digitized by Google

is moved forwards by electric motors driving three-throw pumps by means of worm-gearing, which gives a pressure up to 1,700lb. per square inch. These pumps (Figs. 11 and 12) are placed on rails and fastened by a wire rope to the "shield," so that they advance with it. The motors are made by Paterson and Cooper, and are of their $9\frac{1}{2} \times 4\frac{1}{2}$

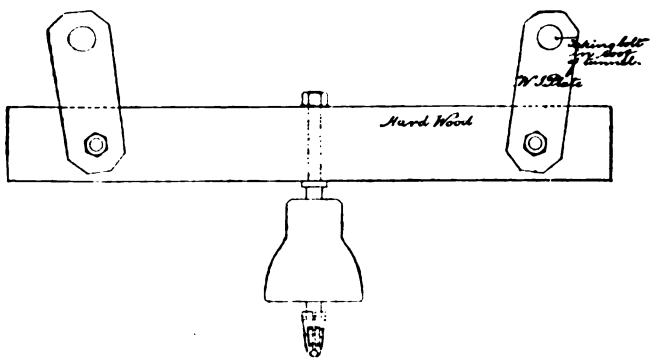

FIG. 9.—Detail of Line Support.

size, series wound, taking 35 amperes at 200 volts when running at 1,400 revolutions. The pumps are by Gwynne and Co., and are of the three-throw type, with rams $1\frac{1}{2}$in. diameter and 3in. stroke.

The lighting of the tunnel is carried out by incandescent lamps connected to bare wires supported on insulators, and these extend up to the face, where additional lights are required. The wires for lighting and power purposes are carried through the brickwork of the air-lock in iron tubes fitted in with an insulating compound. The four faces, the engine-room, and the offices are connected by telephone to a small exchange at the bottom of the shafts. The telephones use the same earth circuit as the locomotives—viz.,

the iron tube—and not the slightest disturbance is noticed rom this method of working.

Messrs. Mowlem and Co. are to be congratulated on the successful working of their electrical plant, and great credit is due to their electrical engineer, Mr. Allen, for keeping the traction plant in good order.

THE WESTINGHOUSE UNDERGROUND SYSTEM FOR ELECTRIC TRACTION.

The Westinghouse Electric Company having developed the Wheless contact system of collecting current from underground conductors in America, are now placing the same on the English market. We understand that a contract for the equipment of a line on this system is likely to be signed at an early date; but in the meanwhile a most interesting working model of a car and track is on view at the company's offices in Victoria-street, Westminster. The system has been in working in Washington for about 18 months, and has given satisfaction. The Westinghouse Company have also equipped the railway

In this new system the ordinary electric car such as is used in either of the other systems is employed. This car carries a small battery, the poles of which are attached to collecting bars placed under the car, which make contact with small iron discs, which project from the roadway. These bars are approximately the length of the car, so that as long as the car covers a set of points they are connected to the battery above referred to. Two of these discs, or points, as they are called, form the terminals of the wires of a small electromagnetic switch, placed in a box buried at the side of the roadway in the case of a single-track and between the tracks in a double-track line system. When the current from the small battery carried by the car passes through one of these switches its armature is attracted, and the current from the main is then switched on to the third contact point, forming part of the group of three in the roadway (Fig. 2). This third contact point is rubbed by a corresponding bar carried by the car, which thereupon becoming charged from the main conveys current to connections from the motor on the car in the usual manner. It will thus be seen that this third point is only connected with the main as long as the current is flowing through the other two contact points from the battery carried by the car, so that when the car has passed over them the

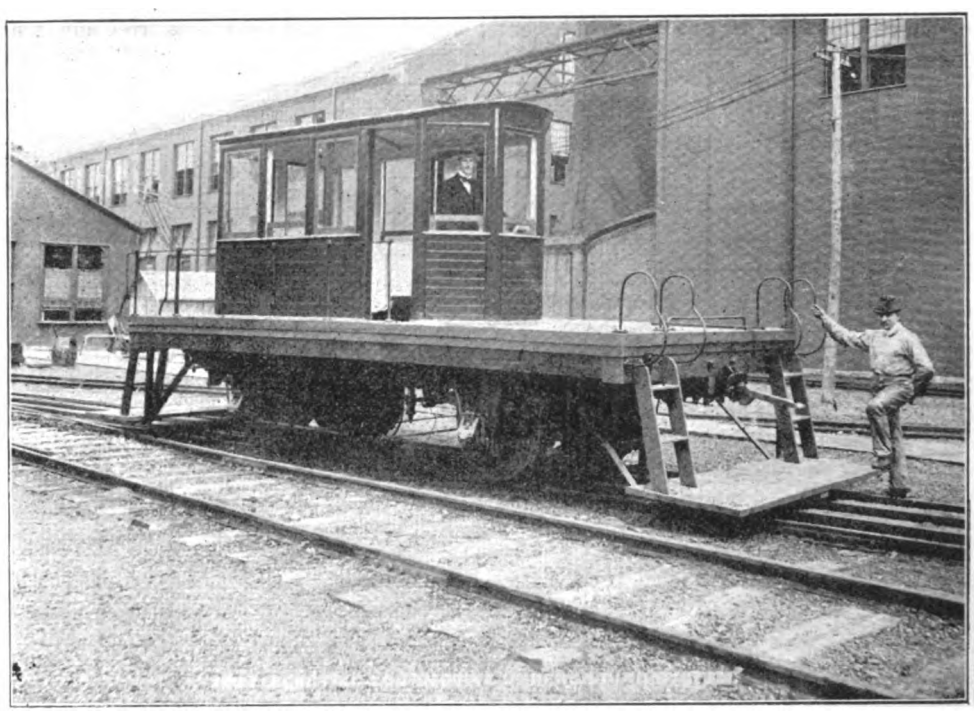

FIG. 1.—Electric Locomotive on Wheless System

sidings, etc., in their large works in America on this design. The locomotive used for this heavy shunting work is shown in Fig. 1, and is capable of dealing with trains weighing 240 tons.

Hitherto the only methods of electric traction actually used on tramways or railways have been the trolley system, the conduit system, and the third-rail system. All these have their disadvantages, and considerable objection has been raised to each of them by the public. The chief objection to the trolley system has been the unsightliness of the overhead wires; and slotted conduits, while avoiding this defect, raise many engineering difficulties in order to ensure good insulation and uninterrupted working in bad weather. Above all, they are costly. The third live-rail system, although much cheaper, cannot be entertained for street work in towns. With it, again, insulation troubles are often incurred. This new system exploited by the Westinghouse Company is a development of many attempts made by Lineff, Gordon, and others to perfect a third-rail system, in which only those portions of the rail under the car are connected to the source of supply. The rail in the road in this case is replaced by contact points only projecting a slight amount above the surface of the road.

current ceases in the electromagnetic switch and leaves the three contact points "dead," so that traffic can pass over them without the possibility of a shock to either passengers or horses. In other words, the entire system is insulated from the supply mains, except at those points which are covered by the car. The groups of points above mentioned project only ¼in. above the level of the road. Each point is about 4in. in diameter, and is made of iron, presenting a convex face to the traffic, the edge being level with the road and the centre about half an inch above. These pieces of iron are corrugated, so that there is no chance of horses slipping on them. They are placed somewhat closer together than the total length of the car, in order that the bars carried by the car make a contact with one set before they leave the previous set, and thus a continuous supply of current is obtained. The number of points in a group may be reduced to two by using the rails as a return, which in no sense lessens the safety of the system.

The construction of the electromagnetic switch is novel, and will be fully illustrated and described in our next issue.

The contact bars on the car are made of flat iron, and extend nearly the full length of the car. In order that they may keep contact in going round curves, they are

Digitized by Google

made in three parts, hinged together, and at the front and rear of the car guiding wheels are placed, which run lightly in the ground rails, and keeps the ends of the contact bar always over the centre of the track. This can be seen from Fig. 3, which shows the model car on the track laid down at the offices of the Westinghouse Company. The system, as arranged with three contact points (Fig. 2), is provided with an insulated return wire, but as the automatic switch is single-pole the left-hand point of the two points used for switching purposes is permanently connected to this return. The switch only connects the single point in advance of these two to the leads, and disconnects it again after the car has passed. It follows that, in order to render the return points harmless, the whole return system must be earthed, otherwise the potential of this point may be at times dangerously high. When this is done, the advantage gained over one having a return through the track to a bare return buried between the rails is not so great as at first sight appears. When the rails are used as return, the number of points of collection at each switchbox are reduced to two.

This system is well adapted for use on railways where the length of trains enables very much fewer contact points being used, and the much larger surface offered for contact makes it much easier to carry a far larger current than has been hitherto done; and the safety in only having the contacts exposed at the time that the train is on them will be a great advantage in tunnels or cuttings where workmen are likely to fall against or touch any exposed point.

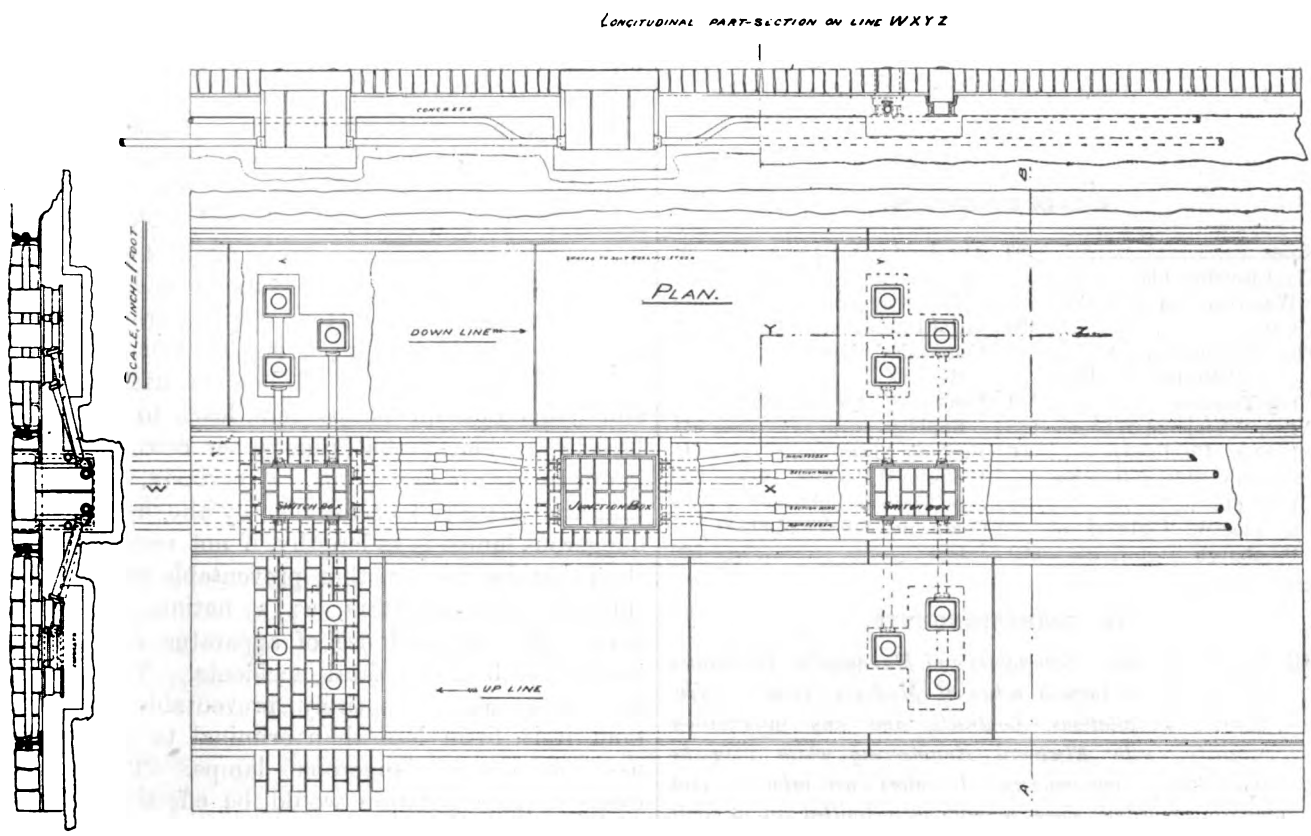

FIG. 2.—Details of Track, with Return Contact.

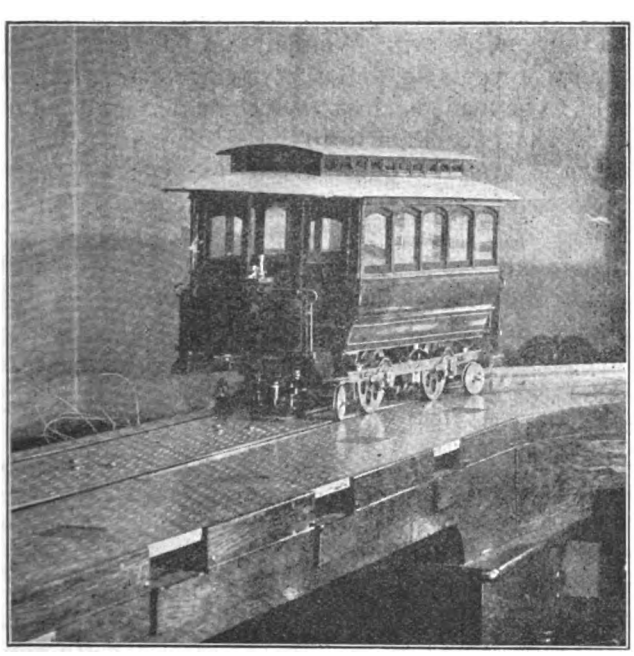

FIG. 3.—View of Model Car.

We are informed that in Washington no difficulty due to snow and ice has been found in keeping the cars running in winter. A regular traffic is stated to keep the track in running order, and the collectors and contact points do not show signs of wear after some 2,000 miles run. The cost of laying down the metallic return, all cables, feeders, switches, and the double track, was about £7,000 per mile of street equipped. In this case the return was through the tracks, but an uninsulated return was laid between the two tracks and bonded to the rails at regular intervals.

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

OIL—GAS—ELECTRICITY.

There is no feeling of gratification in calling attention to the dangers of gas. These dangers are well known and recognised, but here, as in all cases, familiarity seems to breed excessive carelessness. It is easy to cry out for legislation in this and other matters, and if we suggest legislation in certain directions we shall undoubtedly be reminded of our many remarks against precipitate legislative action. However, the text of our sermon to-day is not legislation in or against the interests of gas, or even of electricity. It is in quite another direction. The gas explosion just out of the Strand, which resulted in many injured and one death, ought not to be so appalling as the continuous fatal accidents arising from the use of oil. Here again, perhaps, a too general view will lead to wrong conclusions. It is not altogether the use of oil, but the use of fragile and dangerous oil lamps that leads to accidents. Everybody knows that ninety per cent. of the oil lamps in use are dangerous. Everybody, too, knows that the death-roll occasioned by the use of these dangerous lamps is as lengthy, if not more lengthy, than that due to any other preventable cause. We, hrough our legislators, as a nation, knowingly permit the sale and use of apparatus which must inevitably lead to fatal accidents. These accidents are almost entirely preventable, and we hold it is little less than criminal to permit the use of these dangerous lamps. This is a case where legislation would be effective. There is no use in arguing that men can buy safety lamps if they choose; nine-tenths of the purchasers neither know what constitutes a safety lamp nor the properties of dangerous oil. We are not saying it because fuss ought not to be made, but there is more fuss made over one accident from electricity than over a hundred from oil. The latter seems to be expected as a necessary evil, the former is recognised as a preventable evil. We maintain both are almost entirely preventable, and that stringent restrictions ought to be made against the production and sale of lamps that are known to be dangerous. These questions are not questions of money; they are questions of murder. This is where the curse of modern civilisation sits heavy. Parliament, too eager to buy votes, votes, votes, panders to a lot of sentimental humbug out of the mouths of fools and fanatics, and year after year permits the manufacture and sale of these dangerous articles without let or hindrance. We certainly have an interest in bringing this matter forward, hence must expect what we say to be taken *cum grano salis*. The facts, however, are indisputable. From our point of view we think—we are almost tempted to say we know—that the generation and distribution of electricity for lighting purposes is safer than that of any other illuminant. There is no difficulty in going so far as to say that in the house the use of electricity can be made absolutely safe. There is a danger up to a certain point to careless workmen in the generation and distribution, but there ought to be no danger to the house or the householder. Electrical engineers know this, but they are not half energetic enough to insist upon it; and some of them, the black sheep

Digitized by Google

of the profession, are too eager to get work at any price. The tendency of this policy leads to the wilful neglect of known precautions against danger. Far too lenient a view is usually taken of bad workmanship, and we think this arises from the fact that in the generality of instances bad workmanship does not mean life or death, though it may mean more work in the shape of renewals and repairs. Bad oil lamps, bad workmanship conducing to gas leakage, to unsafe electric wires, are a far more serious matter, and never ought to be treated leniently. So far as the first of these is concerned, we contend that all oil lamps, except safety lamps, should be prohibited by law. As regards the bad workmanship, we can do little more than to constantly point out its dangers, and trust that in future the fire insurance inspectors will penalise such contractors by refusing to pass their work.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XV.—SIMPLE PRINCIPLES AND USE OF ELECTRIC MEASURING INSTRUMENTS — AMPEREMETERS, VOLTMETERS, DELICATE MIRROR GALVANOMETERS, RESISTANCE COILS.

(Specially Contributed)

Purposes of Measuring Instruments.—We have seen that in electrical work there are three fundamental quantities to be measured:

1. Pressure, which is measured in units called volts.
2. Current „ „ „ „ „ „ amperes.
3. Resistance „ „ „ „ „ „ ohms.

It will do no harm to refer once more to terms that are constantly met with in all text-books, and which are often slightly misunderstood. What I have just called pressure is often called electromotive force, or difference of potential. Now, we may take it as axiomatic that any source of electricity, such as a combination of copper, zinc, and sulphuric acid, is capable of exerting one, and only one, electric pressure. This total pressure is the E.M.F. of the source. Frequently, nay, almost always in practice, we have to deal not with the total pressure, but with a part of the total pressure, that pressure, in fact, that is exerted between two points in the circuit under consideration. Call these two points A and B. The pressure at A is something less than the total pressure, and the pressure at B is still smaller. If we say the pressure at A = x and that at B = y, then the acting pressure between A and B is the difference between x and y, or $x - y$. If, for example, the voltage at A is 20, and at B it is 10, then the acting pressure, or the difference of potential, or the P.D., is $20 - 10 = 10$. Once more, then, E.M.F. is the *total* or the maximum pressure, while the P.D., or acting pressure, is the pressure acting between two given points in the circuit. P.D. and E.M.F. are equivalent only when the former refers to the total, while it is usually less than the latter. However, a little care will always show what a speaker or writer means. If he is referring to the E.M.F. of a dynamo it is frequently to the P.D., or acting pressure between the terminals, and not to the total E.M.F. generated by the machine. A certain part of the total pressure generated, whether by a dynamo or battery, is used up in overcoming the internal resistances, and thus only a portion is available for useful external work. It is very much the same in a steam-engine. A part of the steam pressure upon the piston is used in overcoming the frictional resistances of the engine itself, and this part cannot be made available for other useful work.

There is always a difference of pressure between two points if, when those points are put into conducting contact, electricity tends to pass from one point to the other.

The method by which we measure the pressure excited is much the same as the everyday methods used in other cases. There is no difference in the principles employed. Thus, suppose we require to know the largest load a horse can move under given conditions, let us see how we may get to know this. If you harness the horse to a light cart, you will probably find the horse can trot away with the cart with considerable ease and at a good pace. Put a few bars of lead in the cart, and the horse experiences more difficulty in pulling it along. Continue to put more and more lead into the cart; you come to a point where the horse can just move the load, and if a little more lead is put in, the horse is no longer capable of moving it.

If you have steam acting upon—that is, pushing—the piston of a locomotive, the latter being connected in the well-known way to a driving wheel, you have only to put more and more wagons—that is, a larger and larger load—on to the train to reach a point when the engine is no longer able to draw the train.

In both these cases you have a force overcoming a resistance, and you can easily see that a given force will only overcome a certain resistance. If the resistance is below the powers of the engine or the horse, then motion of the load takes place.

Dealing with an electrical circuit, you have a pressure overcoming resistance and giving rise to a current. As the resistance increases the current gets less and less, till past a certain resistance the current—which in this case is the equivalent of the motion in the other cases—ceases altogether. You will easily see that you can get little or no information about the horse's or engine's exertion when there is no motion, but in both cases you do learn something when there is motion—in fact, you have to consider both the load moved and the motion imparted to that load. So in electricity, if there is no current your measurement is at a standstill—you must consider both the resistance overcome and the current. The full force of the engine or of the horse may be exerted with too heavy a load, and may be measured by the interposition of a spring, but we cannot very well interpose a spring when electrical pressure is to be measured, so that although the mechanical measurements may help you to better understand the electrical ones, the likeness is not perfect. The use of a balance again helps somewhat to understand what we have to measure. Here are two scales. In one I put an unknown weight, which is pulled earthwards by gravity. I can exactly balance that pull by putting another weight or other weights into the opposite balance. The known weights are multiples or sub-multiples of an accepted unit, and thus we make our comparisons.

So in some such way we measure electrical pressure. As I have said, the unit adopted is called a volt; but we have no generator of electricity that always gives us an exact pressure of a volt.

Standard Cell—Some years ago Latimer Clark proposed a cell which is fairly constant, and which has been adopted as a standard. It is thus made: pure mercury is covered with a saturated solution of zinc sulphate made into a paste with pure Hg_2SO_4 (mercurous sulphate) and $ZnSO_4$ (zinc sulphate). Pure zinc plunged into this paste forms the negative pole, while a platinum wire fused through the bottom of the cell, or carried down into the mercury in a glass tube from above, is the positive pole. The element is sealed with paraffin. This element when carefully prepared is said to be correct to $\frac{1}{1000}$, but only for currents not exceeding 0·0001 ampere. At a temperature of 15deg. C. it gives 1·434 volts. According to Lord Rayleigh, at the temperature t it gives $1{\cdot}437 - 0{\cdot}001\,(t - 15)$ volts.

If, now, I have a battery which causes a current to traverse a given resistance 10 times larger than the current traversing the same resistance from a standard cell, then the pressure of the battery is 10 times that of the cell, or $1{\cdot}434 \times 10 = 14{\cdot}34$ volts at 15deg. C.

Another way to find the unknown pressure would be to add standard cells in series, so that the pressure from the cells was opposed to the unknown pressure. As the

Digitized by Google

pressures would be opposed the current would be lessened, and when the pressures balance there would be no current. By counting the number of standard cells in series, and multiplying this number by the pressure of one cell, we should get the amount of the balancing pressure, which would be the equivalent of the unknown pressure. Of course this would be a cumbrous and ofttimes an impossible method of procedure, but I prefer you to understand the principles as well as to understand the practical methods adopted.

Current Measurement.—There are three ways in use by means of which we can measure an electric current :

1. By electrolysis.
2. By its magnetic action
   α, upon a magnet ;
   β, upon another conductor carrying a current.
3. By its heating properties.

By Electrolysis, matter is presented to us in one of three forms—solid, liquid, or gaseous. The chemical action of an electric current is generally confined to certain liquids and solutions, and to the process of decomposing a liquid by means of a current the term electrolysis has been given. Matter in whatever form presented, if it consists of one substance only, is said to be an element ; if it can be split up into several substances, it is termed a compound. You cannot split up an element, therefore you cannot electrolyse it. The liquids that can be electrolysed must therefore be compounds. They must also be conductors. From the electrolytic point of view, we may regard liquids as of three kinds :

1. Elements, such as molten iron, lead, etc.
2. Non-conducting compounds, such as various oils, resins, turpentine, benzine, etc., and probably *pure* water.
3. Conducting compounds, such as water, dilute acids, etc. ; solutions of metallic salts, as sulphate of copper, nitrate of silver, etc.

(To be continued.)

THE JANDUS ARC LAMP.

As mentioned in our last issue, this lamp is so designed as to preclude oxygen from reaching the arc. The result is that the carbons consume very slowly, saving much time in trimming and carbon renewals. This is by no means the first attempt to attain this end, but difficulties in detail have removed earlier rivals from the field.

The Brougham and André lamp, which was exploited in 1889, used the same principle. This lamp was one of that large class, now almost extinct, which were called semi-incandescent. In this lamp the light was obtained from the point of contact between a thin carbon and a large carbon or metallic block. A description of the lamp in the *Engineer* of March 12, 1880, says : "It was seen that if a carbon could be rendered incandescent in a vacuum or in some gas which would not combine with it, one source of waste would be prevented. Several inventors worked on these lines, and Mr. André, following in their footsteps, contrived to make a very good lamp. It was not quite perfect, but so far as can be judged from a lamp which we have seen in operation at the works of Messrs. Paterson and Co., the improvement effected by the Hon. R. T. D. Brougham will place it before any other lamp on this principle now in use. The value of the improvement will at once be seen when we state that it reduces the carbon consumption to about ·125in. per hour, whilst a similar carbon burnt in a lamp open to the atmosphere burns about 6in. per hour. The cost of carbons is thus reduced to one forty-eighth of what it would be in an ordinary lamp.

The improvement consists in surrounding the lamp, or a portion of it, with a separate vessel of glass containing water or some other suitable liquid—the glass globe of the lamp thus being surrounded by a second globe containing a liquid. In this way the liquid prevents any oxygen getting to the source of light, and that contained in the inner globe is soon converted into carbon dioxide."

Mr. William Jandus, of Cleveland, Ohio, has evidently been working on the subject *de novo*, as his first patent specification issued in England, and dated November 17, 1891, only claims a saving in carbon of 85 per cent. of the quantity used when the air has free access to the arc. At this time he used one globe only, and that was hermetically sealed at the top, but open at the bottom. In this way only the circulation due to convection was prevented, and the diffusion of air into the space doubtless aided the combustion of carbon. In this early lamp the form of the containing globe was similar to that of the inner globe in the present lamp (Fig. 1), but it was attached to the upper carbon-holder, and moved down as the lamp fed. In the drawing attached to the specification a Jablochkoff candle was shown in a completely closed globe. The next patent granted to Mr. Jandus is dated January 23, 1894, and contains the essential feature of the lamp now being placed on the market by Messrs. Drake and Gorham.

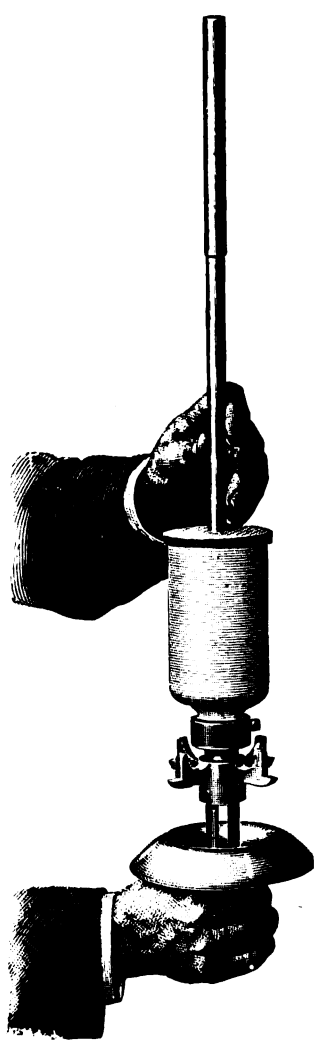

FIG. 1.—View showing the Method of Trimming the Jandus Arc Lamp.

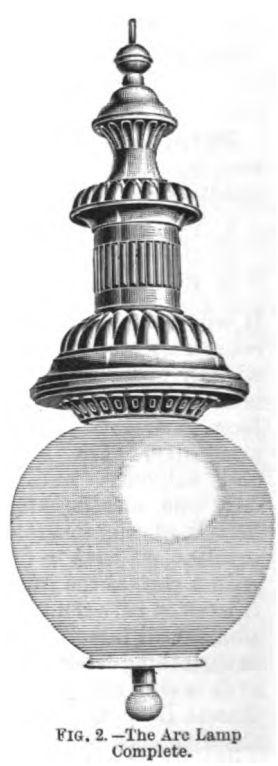

FIG. 2.—The Arc Lamp Complete.

The arrangement for keeping the arc surrounded by an inert gas has in this later Jandus lamp been arranged as follows: A small cylindrical globe surrounds the arc, as shown in Fig. 1. This globe rests on the casting forming the lower carbon-holder, and is roughly closed at the top by a metal plate, which, however, does not fit tightly round the upper carbon.

The outer globe (seen in Fig. 2) surrounds the whole, and is attached by an airtight joint to the upper part of the lamp. At the bottom there is an opening sufficiently large to enable a hand to be put in for the purpose of cleaning the globe, etc. This circular opening is closed by the saucer-shaped metal disc on the lower carbon-holder (Fig. 1). This is pressed against the globe by a spring, so that any rise of pressure of the gas inside the globe moves the disc and so is relieved. It does not absolutely prevent ingress of air to the globe, but as there is no other opening there can be no circulation. What happens when the lamp is switched on is about as follows : The arc quickly

Digitized by Google

consumes the whole of the oxygen in the inner globe, and by the rise of temperature a considerable amount of air is expelled from the orifice at the bottom of the large globe. In a short time the air in both globes will be converted into a mixture of carbon monoxide, carbon dioxide, and nitrogen. It is probable from the conditions that carbon monoxide is the chief oxygen compound. In other lamps of the same make and principle, but which had not equally good arrangements for excluding oxygen, a considerable blackening of the globe has been observed. It is claimed by the inventor that when the gases in the inner globe reach a temperature of 600deg. F. this depositing action ceases. With certain carbons a whitish siliceous deposit is obtained, but by the careful selection of good carbons the Jandus lamp is free from the above defect.

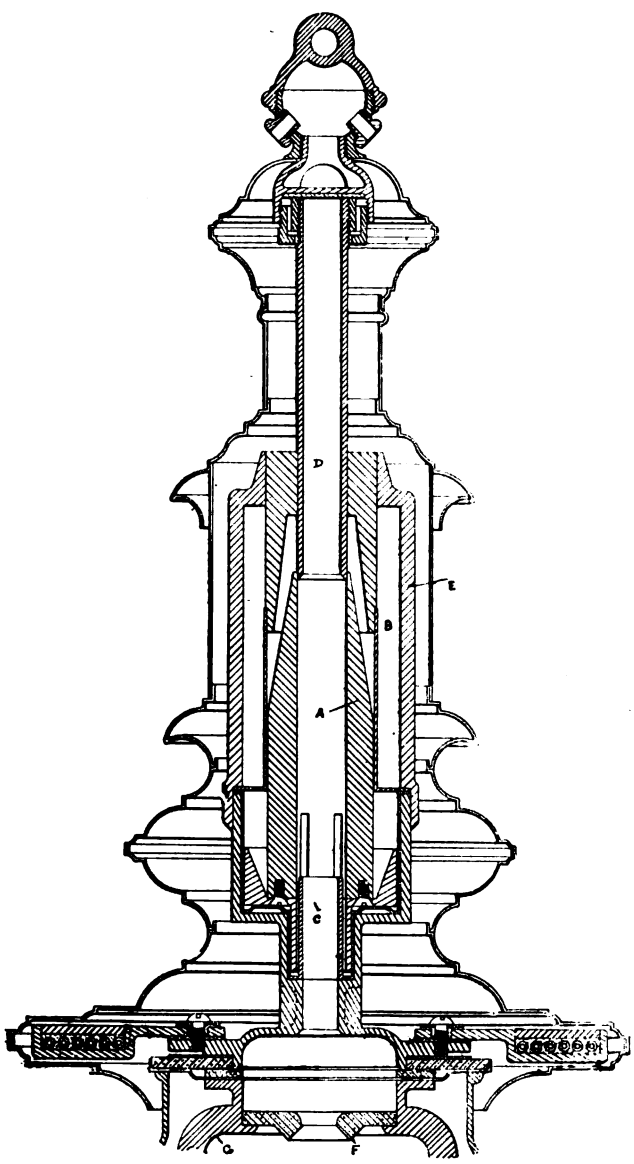

FIG. 3.—Section of the Jandus Arc Lamp Mechanism.

As would be naturally expected, new characteristics of the arc are found when burning in inert gases at high temperature. The current required to maintain a given length of arc is decreased, and there is no difficulty in keeping an arc $\frac{5}{8}$in. long with only five amperes flowing, but about 80 volts are required at the terminals. The ends of the two carbons do not then form into a point and crater respectively, as in ordinary direct-current arcs, but burn to flat ends the full diameter of the carbon. There are signs on the ends of the carbon that the arc is continuously moving round, but there is no hissing noise given off, as would be expected, and also no flare. The light given from the two flat-ended carbons $\frac{5}{8}$in. apart gives a different polar curve of intensity to that obtained with the arc in air. No definite measurements have been made up to the present, but Messrs. Drake and Gorham tried the following neat rough test: A strip of sensitised paper was fastened round a vertical segment of the globe for a short time. The same was done for an ordinary arc lamp having the same diameter globe. The two strips were then compared, and the intensity of the light in any direction could be seen approximately by the colour of the paper. It seems from this that the ray of maximum intensity is nearer the horizontal in the Jandus lamp than in the other types, but that the ratio between maximum and mean ray is less. In other words, the polar curve is not so peaked. The next point in issue is the question as to whether the old belief that the light given by an arc is roughly proportional to the current holds under the new conditions. Messrs. Drake and Gorham, from rough photometric tests, state that the light per watt is practically the same for the Jandus as for an arc lamp burning in the air with the same length of arc. Unfortunately, this is comparing the Jandus lamp in its most favourable condition with an ordinary lamp in abnormal conditions. The Jandus lamp, however, loses a large proportion of its light owing to the two diffusing globes. Therefore at the present time there is no evidence to show whether the lamp compares favourably or not with its older rivals in point of lighting efficiency. On the score of cost of trimming it is far ahead, as one pair of carbons will last some 200 hours, and doubtless this saves fully as much in labour as in cost of carbons. The details of the feeding mechanism are most carefully designed, and present many novel features. Fig. 3 shows a section of the lamp, but, unfortunately, the details of the feeding and self-centreing gear are incomplete. A is the moving armature of the electromagnetic system, E, which is all arranged concentrically with the upper carbon. The series and shunt winding come in the space, B, but are not shown in the section. The upper carbon, and the brass tube attached, which can be seen in Fig. 1, is pushed up the centre tube, C D. The end, C, of the lower fixed guide is cut away at the top, leaving four sections projecting. Between each of these a brass wheel is placed, which touches the inverted cone on the armature at either the carbon rod or the end of the tube, C. In the normal condition these wheels grip the carbon, but when the arc gets too long the armature lowers till the wheels touch the end of C, and thus relieving the pressure on the carbon, allows it to feed. A somewhat similar but even more ingenious self-centreing arrangement is employed, by which a series of rings supply current to the carbon, and at the same time centre it. This comes in the space above F in our illustration. The added resistance for the lamp is arranged round the rim of the case and can be seen in the section. The lamp normally takes 80 volts, so that about 20 volts is absorbed in this resistance when the lamp is worked on a 100-volt circuit.

The lamp with two diffusing globes gives a splendid light for interiors, where a glaring spot of light should be avoided.

THE ELECTRIC LIGHTING OF EDINBURGH.

BY HENRY R. J. BURSTALL.

(Concluded from page 476.)

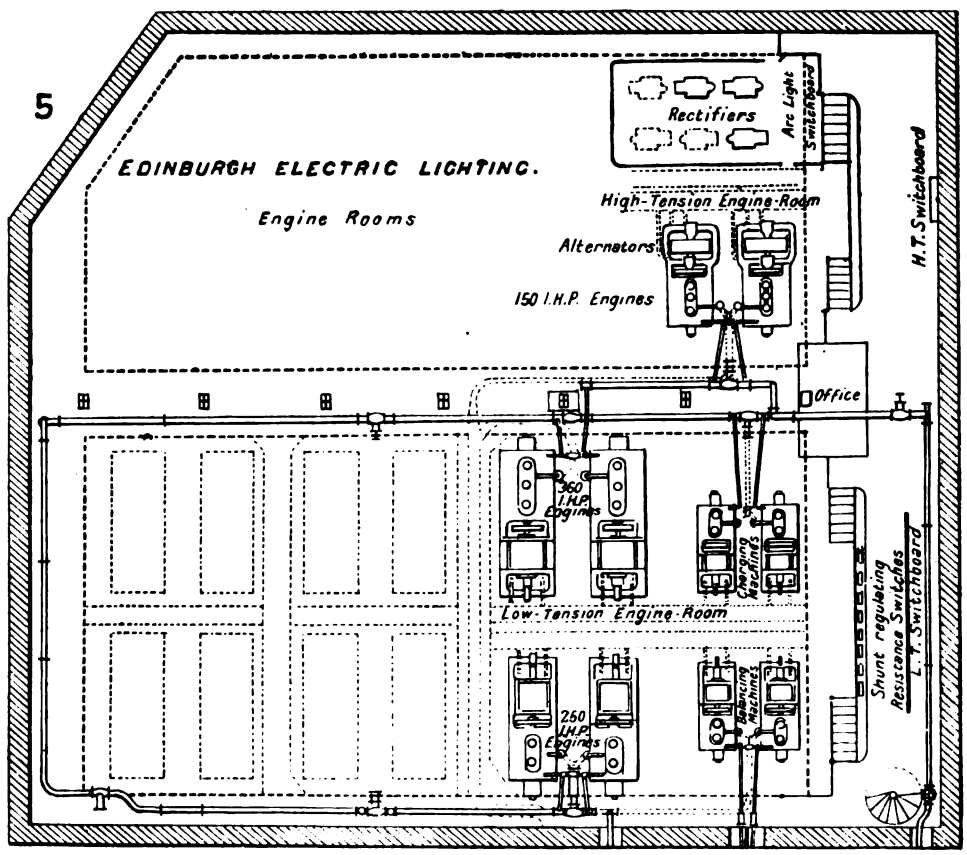
ROADWORK.

Distributing Mains.—Practically the whole of the distributing mains are laid as cable insulated with indiarubber, heavily braided, drawn into Doulton stoneware casing under the footways, and into either Crompton-Davis cast-iron casing or cast-iron pipes under the roadways. At all crossings, and at intermediate places on the footways, brick junction-boxes are built for the purpose of drawing in, connecting, and testing, and smaller brick boxes are provided at suitable intervals, where connections are made to consumers; but for this purpose, when space is limited, a special length of Doulton casing is provided, which is so made that it can be easily split longitudinally and removed; the house connection is then made with vulcanised joints, and the casing replaced and jointed up with a special collar and bitumen cement. The collar is provided with a socket, into which the pipe carrying the house connection can be jointed. A mark is made on the kerb to indicate the position of the service box, and the pavement is then replaced. These service boxes are found to be of great use owing to the number of cellars under the pavement. The brick junction-boxes are covered with a cast-iron frame, which is fitted with a cast-iron cover filled in with concrete, a water tight joint being made with the frame. In most places the

Digitized by Google

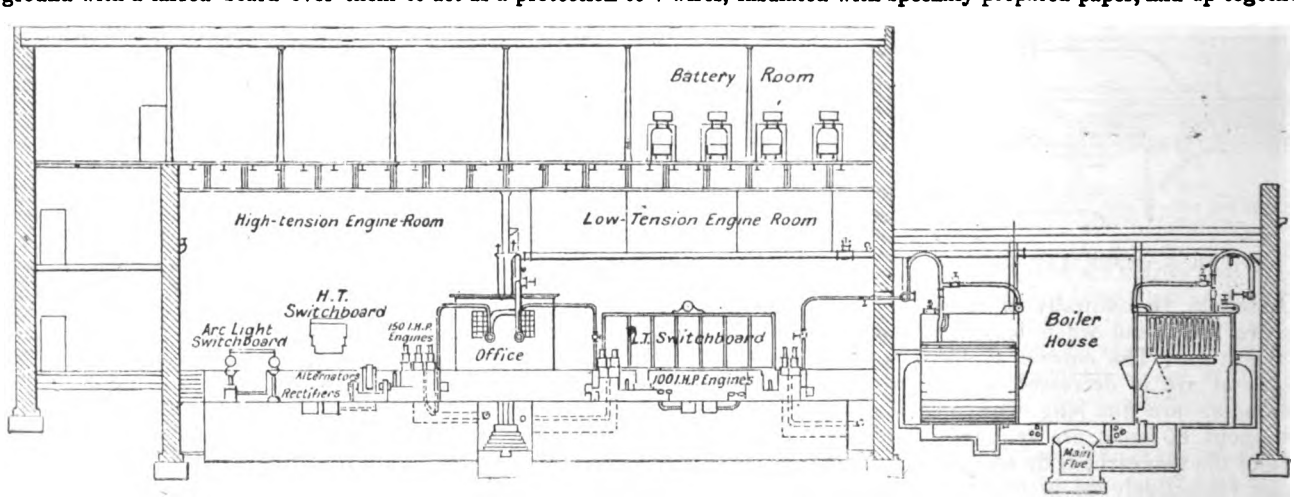
bottom of the box is filled in with dry rubble so as to form a drain for any water which may find its way in; but where water has been found in the soil the bottom of the box is concreted, and the whole made water-tight. Where it has been necessary in some places to put junction-boxes in the road they have been made as water-tight as possible, and covered with a double cover, the upper being a heavy cast-iron cover with wood blocks let into it. Boxes in the road have been avoided as much as possible, as it is found so difficult to make a satisfactory job of them. In a few places the distributing mains have been laid as bare copper strip, carried on stoneware insulators in concrete culverts.

Feeders.—Wherever sufficient space has been found under the footways, the feeders have been laid as bare copper strip, carried on stoneware insulators in concrete culverts. Across all roads, and where there has not been sufficient space for culvert, the feeders are laid in Siemens armoured cable, laid direct in the ground with a tarred board over them to act as a protection to them and as a warning to any workmen opening the ground. The cable has everywhere been laid of greater section than the copper strip in the rest of the feeder, so that the capacity of the feeder can be largely increased and yet the resistance be kept right by pulling in additional copper strip into the culverts without bringing the current density up to any excessive amount in the portions laid in cable. Thus the feeders can be made to carry considerably more current than that for which they are now designed, with the same drop of E.M.F., and without either disturbing the streets or overrunning any of the cables. All the feeders have been designed to have a total drop of 44 volts at full load. In the culvert the copper strip is laid in lengths of about 20 yards, with a brick inspection-box at each joint; so that the culvert can be easily seen by means of a lamp pushed into it, and the strip can be readily drawn out and in, as required. The joints are made by tinning the ends of all the strips, and clamping them together by a gunmetal grip-box with two ⅝in. bolts; at the feeding points the feeders are connected to the mains by short pieces of cable. Everywhere the culvert is kept quite straight in plan, but with a fall towards every junction-box or inspection-box. The strip is in no place lower than 2ft. below the level of the pavement; for it has been found elsewhere that it is impossible properly to inspect or do any work to culverts which are constructed at any great depth. There is nowhere any culvert under a roadway.



Plan of Engine-rooms.

Potential Leads.—These lines, by which each feeding point is connected back to the station, consist each of three sets of wires, insulated with specially prepared paper, laid up together, and covered with the same material, a lead tube being drawn over the whole. These leads are drawn into special ways, either in Doulton stoneware casing or cast-iron pipe, laid alongside the culverts, and are joined up into one length back to the station. The joints are made in a brass tube, soldered on to the lead sheathing, and containing insulating oil; the wires are kept separate from one another by fibre discs.



Section through the Edinburgh Electric Light Station.

Connections.—The whole of the cable connections are made by cone connectors sweated on to the cables, and fitting into gunmetal connecting-blocks. The cones are all the same size

Digitized by Google

for all sizes of cable, and are interchangeable; when the section of cable exceeds 0·7 square inch, two cones are used; the taper employed is 1 in 11, which makes a good fit and is yet readily

of altogether 176 public arc lamps. In the streets dotted black the arc lamps are run four in series off the distributing mains shown by red lines, and each series of four is provided with a

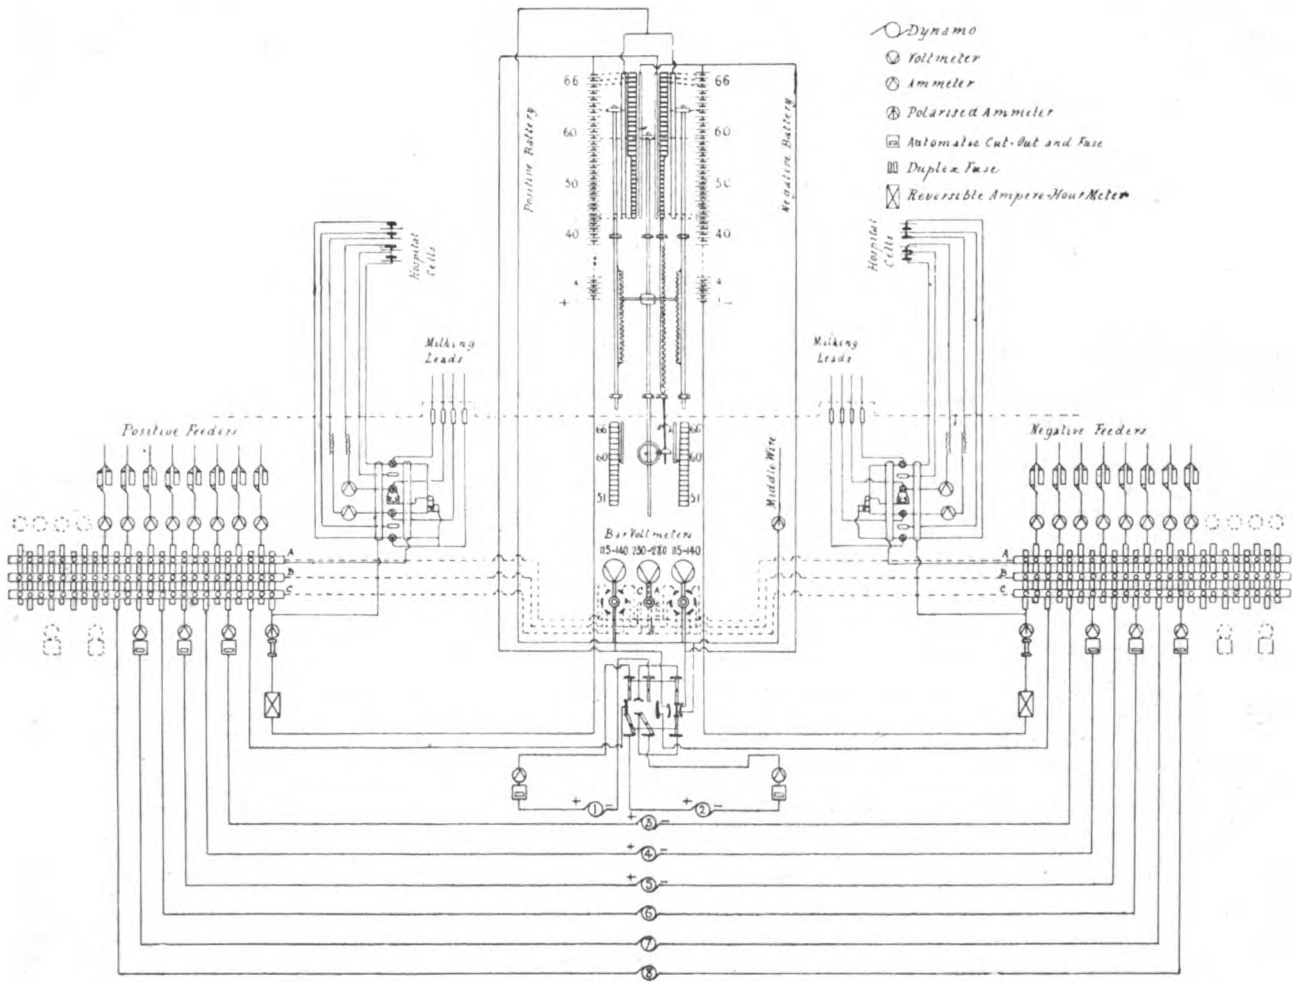


Diagram of Low-Tension Connections at Edinburgh.

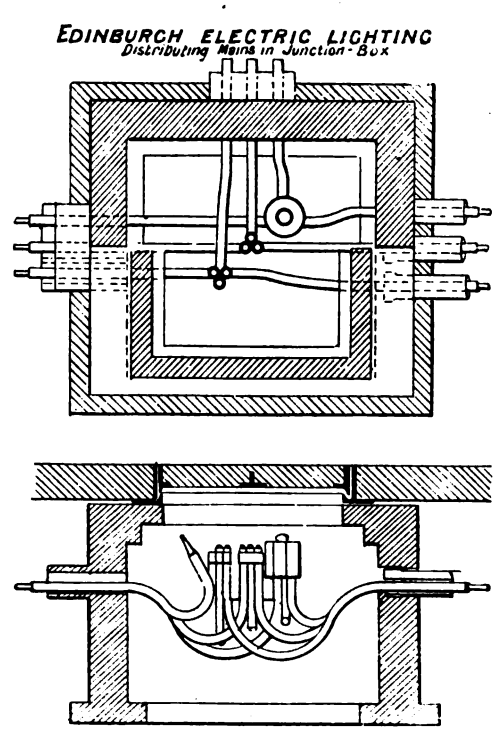
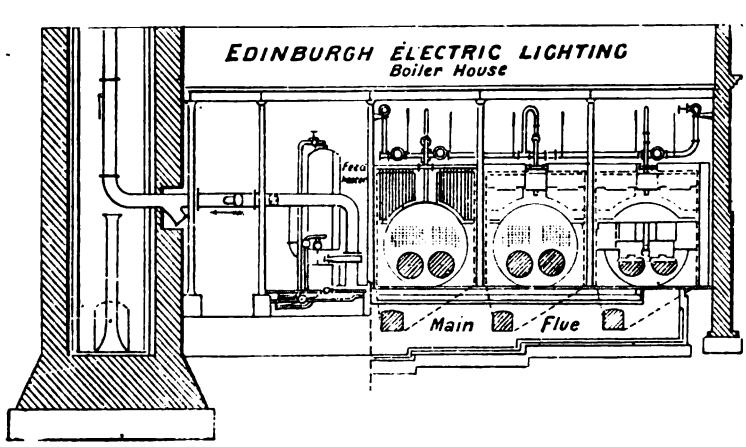
disconnected. The cone connecting-blocks are made in four sizes, having two, three, four, or five holes bored in them. The holes are bored conical to fit the cones on the cable connectors, and the blocks are interchangeable with one another. The armoured cables, which are all of large section, have special connectors sweated on to them, and these have either one or two of the standard conical holes bored in them; the connections to the distributing mains are then made by one or more short lengths of cable having cone connectors at each end. Enough slack is left in the boxes to allow the ends of the cables to be turned upwards; they are then connected together by slipping the connecting-block on them, and the cones are drawn tight into the holes by means of a nut fitting upon a $\frac{3}{8}$in. screw on their ends. In order to obviate any trouble from end leakage through water dripping on the bare terminals, and also to minimise the risk of short-circuits through accidental contact

fuse, switch, and line resistance. Each lamp in the series is also provided with an automatic device, which, in the event of the lamp failing, cuts it out and introduces into the circuit a resistance equal to the lamp, so that the other lamps in that





Section of Boiler-house.

between the blocks, stoneware caps are dropped over the connectors, and entirely cover all bare metal.

Public Lighting.

The streets tinted on the map are lit by electricity, by means

circuit are not affected. The lamps in Princes-street are constructed for a normal current of 15 amperes, and all the other low-tension lamps for 10 amperes.

In the streets tinted purple, in which no low-tension mains are laid, the lamps are run on special high-tension series

Digitized by Google

circuits from the rectifiers at the station. There are at present two series circuits, both of which are laid in all the streets lit by high-tension lamps, and the lamps are connected alternately to each circuit. The circuits are laid as concentric cable drawn into cast-iron pipes, the outer conductor of the cable being insulated. There are 24 lamps on each circuit, each provided with an automatic cut-out in case of its failing to act, and also with a switch in the pillar, by which it can be entirely disconnected from the circuit if necessary, while the switch is so made as to complete the circuit for the other lamps.

In arranging the circuits for the arc lamps, care has been taken to put alternate lamps on separate circuits in all streets, whether run from the distributing mains or from the series circuits. This minimises the risk of any street being left in darkness by the failure of any circuit; and also allows half the lamps to be switched off at or about midnight, still leaving the streets well lighted. The arc lamps are of Crompton-Pochin type, and are fitted with 18in. spherical globes. They hang from the bracket of a cast-iron pillar, the centre of the globes being 23ft. above the level of the pavement. In Princes-street the lamps are about 45 yards apart, and are on one side only of the street. In the other parts of the city the lamps are about 60 yards apart, and are placed alternately on the two sides of the street.

No contractor was employed for the roadwork or laying of the mains; the whole of this work, including the erection of the arc lamp-posts, was carried out by the resident engineer, Mr. E. W. Monkhouse, with his own staff of workmen. The armoured cables were supplied by Messrs. Siemens Bros. and Co.; the unarmoured cables by the Henley's Telegraph Works Company, and the India Rubber, Gutta Percha, and Telegraph Works Company, Silvertown. The potential leads were supplied by the British Insulated Wire Company. The stoneware casing was manufactured by Messrs. Doulton and Co., and the cast-iron work by Messrs. Maclaren and Messrs. Shaw and Co., of Glasgow. The copper strip was supplied by Messrs. Bolton and Co., of Oakamoor Works. The posts for the arc lamps were designed by the Edinburgh School of Art, and the castings were made by Messrs. Mackenzie Bros., of Edinburgh. The whole of the arc lamps were supplied and fixed by Messrs. Crompton and Co., of Chelmsford, who also supplied the cable cones and connectors.

In this account of the electric lighting of Edinburgh the author has endeavoured to describe the arrangement of the plant and mains, and any details in their design and construction which may be of interest, without discussing general principles or the advantages or disadvantages of any individual system. Having himself had the good fortune to be connected with this particular work from its earliest stage to its opening, he desires to express his deep indebtedness to Prof. Kennedy for permission to prepare the present paper and to use the drawings from which the diagrams have been enlarged; and also for his suggestions and assistance, without which it would have been impossible for this paper to be laid before the institution.

THE PORTRUSH AND GIANT'S CAUSEWAY TRAMWAY.

INSPECTOR'S REPORT.

The following is the report of Major Cardew on the enquiry held at Portrush on September 25 and 26, 1895, into the causes of a fatal accident to a person named Thomas Walne on the Giant's Causeway Tramway:

"To the Assistant Secretary, Railway Department, Board of Trade.—Sir: I have the honour to report that, as appointed by the Board of Trade, I held a local enquiry as above The enquiry was held in the Town Hall, Portrush, and occupied two days The complainants, on whose application the Board of Trade decided to hold this enquiry, are certain ratepayers of the district traversed by the tramway. Mr. William Moore, barrister (instructed by Mr. T. Taggart, solicitor) appeared on behalf of the complainants; Mr. W. H. Leech, solicitor, on behalf of the tramway company. Besides hearing statements and taking evidence, I carefully examined the line throughout, and the station where the electric power is generated. The tramway upon which the accident occurred is a line six miles in length, constructed under powers given by the Giant's Causeway, Portrush, and Bush Valley Railway and Tramways Act, 1880, between the town of Portrush and Bushmills, along the side of the public road, and an extension, which is more properly a railway, two miles in length, across private property, to a terminus in the immediate vicinity of the Giant's Causeway. The line is worked chiefly by steam-engines, but, in addition, electric motors are provided in a few of the cars, and electric power is supplied to these, except for the portion of the line within the town of Portrush, where steam power is used exclusively. The electric power is supplied from a generating station at some distance from the line by means of overhead wires, the energy being obtained from water power. The charged conductor, by contact with which the electric current is transmitted to the motors on the cars, is a stiff iron rail supported at a height of about 18in. from the ground on the side of the tram rails next the hedge or boundary of the road. At road crossings, and at gateways into fields, the conducting rail is omitted for the requisite length, and connection effected by means of an underground cable across the break of continuity. The return circuit is provided in the usual way by means of the tram rails, copper bond wires being used to connect together the several lengths of rail. No attempt has been made to secure the public using the road or cattle driven along it from contact with the charged conductor rail. The inspection was made on the afternoon of the 25th inst. I found that the regulations imposed by the Board of Trade had been disregarded in many particulars, as follows: Regulation V., entirely disregarded. Regulation VI., ditto. Regulation VII., I do not consider the voltmeter in use efficient for the purpose, as although it appeared to be approximately correct in its indications, it was far too small to be read conveniently at the distance at which the man stands to regulate the current Regulation IX., entirely disregarded. Additional regulation as to notices along the line insufficiently attended to. I only saw three such notice boards, and the inscription on these was almost obliterated. By-law IV. disregarded in the cars I saw. I took several tests of the electric pressure at the station at Bushmills, being the nearest point of the line to the generating station, and at the generating station itself. The volts on the line varied considerably, the highest reading I obtained being 310, and the average about 290. At the station the readings were much the same As the regulation was entirely by hand, I tested what would be the effect produced by ordering the attendant to leave the regulating wheel alone, as if he had been suddenly incapacitated Under these circumstances the pressure only rose to about 320 volts. The water was, however, rather low at the time, and at periods of full supply no doubt a greater rise of pressure might be produced; indeed, Mr. Boyd, the inspector to the tramway company, stated that the highest he had observed at any time at the generating station was 360 volts. The charged rail appeared to me to be a decided obstruction, especially at road crossings and in front of field-gates. It seemed to me hardly practicable for a man to drive a herd of cattle along the road, or into a field abutting it, without great risk of one or more animals receiving a shock.

"*Conclusion.*—Having carefully considered the evidence produced at the enquiry held by me, and the observations made at my own inspection, I am of opinion (1) that Thomas Walne died from the combined effects of severe injury caused by the fall across the rail and electrical shock; (2) that the tramways in question are at present, when the insulated rail is electrically charged, a danger to the public and an annoyance to the ordinary traffic; (3) that the Giant's Causeway, Portrush, and Bush Valley Railway and Tramways Company have not paid sufficient attention to the regulations imposed upon them by the Board of Trade. As to (1), I consider that the lethal effect of the electric current was due to the large extent of contact made by the body of deceased with the charged rail, the considerable pressure—viz., a large portion of the weight of a man nearly 13 stone—with which the contact was made, and the length of time (at least several minutes) during which the current was passing through his body. With regard to (2), it must, of course, be borne in mind that this electrical tramway was one of the earliest constructions of the kind. In my opinion, the danger that has undoubtedly existed has been largely due to the position of the charged rail at a height of about 18in. from the ground. Had this rail been placed at the ground level it would have been far safer than it is at present, while if it had been raised to a height of not less than 8ft. from the ground, and greater width of opening allowed at gateways and road crossings, I think that with proper regulation of the electric pressure the working of the line would have been practically free from danger. As at present arranged the charged rail is easily touched by man or beast, and the effect of the shock is exceedingly likely to cause a fall across the rail, which in itself must probably produce physical injury, and also such a contact of the body with the rail that the resulting electric current is large enough to cause death unless assistance should be given at once. With regard to (3), the tramway company allege that they have found a practical difficulty in complying with some of the regulations imposed upon them by the Board of Trade. There may be some grounds for this statement, but this difficulty should have been brought to the notice of the Board of Trade with a view to the modification of these requirements, and even this excuse does not extend to all the failures on the part of the company to comply with regulations.

"*Recommendations.*—I recommend that the tramway company should be required, under the provisions of Section 20 of the Act of 1880, to remove without delay the danger and annoyance to the public which have been proved to result from their existing arrangements by adopting one of the following (three) remedies—viz.: (1) To remove the existing charged rail altogether and adopt an overhead system, in which case the limit of electrical pressure might be reconsidered. (2) To raise the existing charged rail to a height of not less than 8ft. from the ground. (3) To effectively protect the existing charged rail, as suggested by the complainants. This expedient, however, appears to me to be difficult to carry out, and in all respects the least desirable of the three. The tramway company should also be required to exhibit in a conspicuous position at their Bushmills station an efficient and correctly indicating voltmeter connected to show the electrical pressure at this point of their line, and it is desirable that this should be arranged to make a continuous record, but in any case its indications must be clearly visible to the public. Further, the tramway company should be called upon for a full explanation of the failure on their part to

Digitized by Google

comply with the regulations made and imposed upon them by the Board of Trade. In the meantime, I think the company, having regard to the danger which has been shown to exist, should discontinue their use of electrical power until they have carried out the alterations decided upon, working their line entirely by steam power for the present."

LEGAL INTELLIGENCE.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

In the First Court of Appeal (present, the Lord Chancellor, the Master of the Rolls, and Lords Justices Kay, Lopes A. L. Smith, and Rigby), application was made in the case of the South Staffordshire Tramways Company *v.* Ebbsmith and Wain for leave to appeal from an order of Mr. Justice Hawkins refusing to the plaintiffs' inspection of the bank books of the defendant Ebbsmith and of the Dickinson Tramways Appliances Company. The claim alleged as against Ebbsmith was that during the seven years in which he acted as solicitor for the plaintiff company he sold at exorbitant prices worthless patents to the plaintiff company without disclosing the fact that the Dickinson Tramway Appliances Company, which was nominally selling the patents, was, in fact, himself; that he sold land to the plaintiff company which it could not use under its articles of association; and that by means of shareholders created by himself meetings of the company were influenced, and the plaintiffs claimed a return of secret profits alleged to have been made by the defendant while he was in a fiduciary position towards the company. Application was made to Mr. Justice Hawkins for leave to inspect the banking accounts of Ebbsmith and the Dickinson Company, to see what moneys had been paid to Ebbsmith and the defendant Wain, the chairman of the defendant company. This leave was refused, and permission was now asked to appeal. Their Lordships acceded to the application

CLAIM FOR ELECTRIC LIGHTING.

In the Brompton County Court on Friday, before his Honour Judge Stoner, the case of Sabow *v.* Barwise, in which the plaintiff, an electrical engineer, sought to recover the sum of £12 18s. 6d. in respect of electric lighting work done to the order of the defendant.

It appeared from the evidence that the plaintiff became acquainted with two men named Silvester and Foster, who told him that they could introduce business if he would pay them for so doing. It was ultimately agreed that the plaintiff should find the necessary fittings, and that Silvester and Foster should do the practical part of the work, at a fixed rate of 8d. per hour and a share in the profits. The work in question was carried out under that arrangement, but upon application for payment being made to the defendant, it was discovered that he had paid the account to Silvester and Foster. It was contended that the defendant had no authority to pay anyone but the plaintiff, and if he chose to do so it did not rid him of his liability.

The **Defendant** was called, and said he never saw the plaintiff in the matter at all, and never recognised him The order was given to Silvester, who held himself out as principal, and upon the work being completed the account was paid to him

His **Honour** said it was pretty clear to his mind that there was fraud on the part of somebody. It was a hard case for the plaintiff, but under the circumstances there must be a non-suit.

SABOW v. BENSON.

This was a similar claim, arising out of precisely the same circumstances, but without going into the details his Honour entered a non-suit, and told the plaintiff that if he could prove fraud against his workmen he had better prosecute.

E. E. RIES AND A. H. HENDERSON v. THE METROPOLITAN TRACTION COMPANY, OF NEW YORK, AND THE METROPOLITAN RAILROAD COMPANY, OF WASHINGTON.

Messrs. Elias E. Ries, of Baltimore, Md, and Albert H. Henderson, of Philadelphia, Pa, have instituted legal proceedings against the Metropolitan Traction Company, of New York, and the Metropolitan Railroad Company, of Washington D.C., respectively, for infringement of certain letters patent relating to underground conduits for electric railways. The bills of complaint were filed in the Circuit Court for the Southern District of New York on September 17, 1895, and in the Circuit Court for the District of Columbia on October 3, 1895, respectively, through complainants' counsel, Messrs. Price and Steuart, and Mr. James Steuart, solicitors.

It is alleged by complainants, in substance, that the electric conduit railway line recently constructed for the Metropolitan Traction Company and now in regular operation on Lenox-avenue, New York City, as well as the underground conduit railway built by the Metropolitan Railroad Company and in operation on its Ninth-street line in Washington, D.C., severally constitute a direct infringement and violation of certain basic letters patent granted to Mr. Elias E. Ries and owned by the complainants, covering essential features which are used in the construction of the roads in question, and upon which their practicability and successful operation depend.

The patents upon which suit has been brought, and which it is alleged are infringed, are seven in number—as follows: 388 566, granted March 23, 1886 conduit for electric and cable railways; 370,283, granted September 20, 1887, underground conduit for electric and other railways; 383,770, granted May 28, 1888, underground conduit and collectors for electric railways; 386,085, granted July 10, 1888, electric railway; 386,087, granted July 10, 1888, combined electric railway and wire conduit; 409,756, granted August 27, 1889, electric railway crossing; 409,755, granted August 27, 1889, underground conduit for electric railways.

WESTERN ELECTRIC COMPANY v. THOMSON-HOUSTON COMPANY.

The United States Circuit Court of Appeals at Chicago on October 8 handed down, among others, an opinion adverse to the Thomson-Houston arc regulator The Thomson-Houston Electric Company was the unsuccessful party in the suit. The action involved a device known as the automatic regulator, which, as to arc lighting, performs a function similar to that of a governor on the steam engine

Suit was begun against the Western Electric Company, praying for an injunction restraining the defendant company from using the regulator and asking for an account The suit came to trial before Judge Grosscup in June, 1894. The Court upheld the contention of the Western Electric Company that the second patent, which it was claimed was being infringed, was voided, because of the prior issue of the patent covering the device An appeal was taken to the United States Circuit Court of Appeals, which affirmed Judge Grosscup's ruling.

COMPANIES' MEETINGS AND REPORTS.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

The ordinary general meeting of the Brazilian Submarine Telegraph Company, Limited, was held on Wednesday at Winchester House, E C., Sir John Pender, M.P., presiding.

The **Chairman**, in moving the adoption of the report, pointed out that it showed a steady growth in the telegraphic business. As traffic grew, the directors felt it their duty, when circumstances permitted, to reduce the rates, and the reduction which had come into force since the rate per word was introduced had been very large. The rate to Pernambuco was 9s. a word, it was now 3s. 6d. That to Rio was 13s., to Uruguay 16s 8d., to Argentina 16s. 4d.; they were now 4s. 6d. Those to Chili and Peru were 21s. 4d. and 21s. 6d. respectively; they were now 6s. 2d. That showed that while the Company had been progressing and doing a fairly good business, they had also regarded the people who were contributing to their business. The expenditure showed a decrease of £15 643, due to the absence of any heavy cable repairs. The position with the Brazilian Government was not satisfactory, and he thought that that Government should have shown more consideration for them as the pioneer Company which had helped to build up Brazilian trade by bringing the country into telegraphic relations with the commercial world. It was when they found that the Brazilian Government would not deal fairly with them that they tried to find means to carry on the traffic with Argentina. They had laid a cable across the Andes in conjunction with the West Brazilian Company, and were working that cable and doing a large business. To prevent the Brazilian Government interfering with that traffic they looked out for a fresh station, and pitched upon the Island of Trinidad, which was unoccupied except by land crabs, and which would make an excellent station They had, therefore, asked the British Government to enquire into the ownership of the island, and if it was unclaimed to take it. The Brazilian Government were trying to make a political question out of it, but the Company had no objection to Brazil having the possession of the island if they permitted the Company to use it as a telegraph station.

Mr. J. D Pender seconded the resolution, and the report was agreed to.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.

The ordinary general meeting of the Eastern Extension, Australasia, and China Telegraph Company was held on Wednesday at Winchester House, E.C.

Sir J. Pender, M P., presided, and, in moving the adoption of the report, said the great increase in the receipts during the period under review was almost entirely due to the heavy gold-mining traffic that had so suddenly sprung up with West Australia. Whether the remarkable boom would continue remained to be seen, and, all circumstances considered, it would, perhaps, be wise for him to say but little on the subject. The working expenses, including £29,322 for cost of repairs to cables and expenses of ships, absorbed £95 254, against £80 295 in the corresponding period of 1894. The usual interim dividend at the rate of 5 per cent. per annum had been paid, and a balance of £70,504 carried to the reserve. The shareholders, he thought, would agree with the directors that the affairs of the

Digitized by Google

Company were in every respect in a satisfactory condition. They had reason to be satisfied with their dividends, and the carrying forward of a largely increased reserve fund was an eminently satisfactory feature in the working of the Company. Their plant was in excellent order, and the working of the Australasian tariff arrangement for the fourth year of guarantee, ended April 30 last, resulted in the guarantee figure being slightly exceeded, owing to the exceptionally heavy gold-mining traffic to which he had referred. The development or otherwise of the traffic would be watched carefully by the directors, as would all other matters affecting the interests of the shareholders.

The **Marquis of Tweeddale** seconded the adoption of the report, which was unanimously approved.

AMAZON TELEGRAPH COMPANY, LIMITED.

The first ordinary general meeting of this Company was held yesterday at Winchester House, E.C., Mr. W. S. Andrews presiding.

The **Chairman** said this was simply the statutory meeting, and they had no report or accounts to present. The Board were informed that 119 miles of cable had been already manufactured, and the whole of it was expected to be completed by the end of November. Their expedition would start shortly after that, and they hoped to see their line in full working order pretty early next year. So far as they had gone, their work had been very satisfactorily done by Messrs. Siemens, and they would have a thoroughly good cable and the best and most modern apparatus. The contractors' and the Company's engineers had been up the Amazon and fixed the points for landing the cable and erecting offices and quarters, and the Board expected to have a report from them in about a fortnight. A Stock Exchange quotation had been applied for, and the delay in obtaining it was due to it having been necessary to send certain documents to Rio Janeiro in order that the signatures should be attested by the British Consul there. When these came back everything would be in order.

Mr. Griffiths asked whether, as they had a subsidy from the Government, a dividend could not be paid during the period of construction.

Mr. Cuthbert Quilter, M.P., remarked that advances had been made in the direction of better relations between Brazil and foreign countries, and the amnesty which had been granted to participators in the late revolt would, he hoped, be the close of a very unhappy drama, and would be followed by a period of quiet and prosperity. Until their work was complete they could have no reliable estimate of what the value of their property was, and it would not therefore be prudent on the part of the Board to saddle the undertaking with interest paid during construction, which must, after all, come out of the concern.

The **Chairman** said that, although it would date back to the time of the contract, their subsidy would not be paid until the work was complete, and therefore, being under the Joint-Stock Companies Act, they could pay nothing until then. He concurred with what had been said as to the progress of better feelings between Brazil and this country, though these had certainly been affected by the dispute as to Trinidad. He might remark that, although their cable was called a river cable, the Amazon was not an ordinary river, as at Manaos, where their line terminated. it was 10 miles broad, and in time of floods 30 miles. The only really riverine portion of the route was where the Amazon fell into the Pará.

Mr. Cuthbert Quilter suggested the employment of telephones for working their branch lines, as the climate of Brazil was trying for European operators.

The **Chairman** said their representative in Brazil was enquiring into the matter. Native Brazilians, if properly trained, made very good telegraphists. Nevertheless, they had already ordered several telephones for their branch lines with a view to minimise the use of skilled labour.

There being no resolution, the meeting then terminated with the usual vote of thanks.

MONTE VIDEO TELEPHONE COMPANY.

A general meeting of this Company was held yesterday at Winchester House, which passed the report and accounts, an abstract of which was published in our last issue.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.

The directors report that the profit on the last year's manufacturing account is £4,587, and after writing off the Company's general and trading expenses, the trading account shows a net profit of £2,253 carried to the credit of profit and loss, as against a loss of £6,858 in the previous year. This improvement has been effected without any increase in the Company's very inadequate working capital, out of which £5,202 has had to be spent in necessary additions to plant and buildings. The additions to plant are specially valuable, and are working very satisfactorily. Early in the year the Board decided to convert into a more readily realisable form a considerable quantity of old manufactured stock on hand at June 30, 1894, unrealisable immediately as such, and the consequent loss has been eliminated from the year's profit and loss account. The amount, £3,571, after deducting £625, balance of the sheet license royalties in hand, has been added to the balance of deficiency shown at June 30, 1894. Credit as heretofore is taken in the profit and loss account for £1,250, being the amount of license royalties applicable to the year. Of the managing director's salary, £200 has been charged to capital in respect to the new buildings and plant designed and erected by him for the company. The orders received have increased from 706 in the preceding year to 1,531 in the present year—more than double—whilst the deliveries to customers have been nearly four times greater in volume and practically three times larger in value, notwithstanding that the average selling price has been over £12 per ton lower. This diminution in price is, of course, quite beyond control. It is, however, satisfactory to note that prices are again ruling higher. Comparing the last half-year with the first, the aggregate deliveries to customers to June, 1895, were over three times as large as those to December, 1894. The working expenses show a remarkable decrease with the increase in the business done; in fact, the rate of manufacturing cost has fallen by over 50 per cent. The profit and loss account shows a net profit for the year of £480. That the amount is not larger is chiefly due to two causes—first, to the comparatively small scale of the Company's manufacturing operations owing to its restricted means, as before raising further capital the directors were desirous of proving whether or not the Company could make a profit even under the most adverse conditions; and, secondly, to certain annual charges entailed upon the Company under former administrations in respect to liabilities which are not properly within the sphere of an industrial company, which encroach very seriously indeed upon the profit arising from the Company's trading. The business has now reached a stage when further capital can be reasonably asked for and profitably employed in its extension. The shareholders will, therefore, be asked to increase the Board's borrowing powers, which are now so largely taken up by the land mortgage — not contemplated when the articles were originally drawn, limiting the borrowing powers to £50,000—as after borrowing £35,000 on the freehold, only a small margin is left. Power to borrow, therefore, as may be required, up to £100,000 will be asked for, and the debentures proposed to be issued will in the first place be formally offered to the shareholders. A resolution will also be proposed to reduce the ordinary share capital from £2 to £1 per share. This reduction of capital has no practical disadvantage whatever for the shareholders (as it is intended to arrange with the holders of the preference shares that their interest in the surplus profits shall not be increased at the expense of the ordinary shareholders), but, in fact, affords a distinct gain. The reduction will enable the Board to severely write down the capital value of some of the assets, and so diminish the annual charge on future profits for depreciation, and especially it will wipe out entirely the accumulated loss of past years, which would otherwise have to be cleared off out of profits before any distribution could be made to the shareholders, but, by thus reducing the capital, the old loss will no longer appear in the accounts, and the profits can be divided at once as they are made. Moreover, nearly the whole of the proposed reduction has already been returned to the shareholders in dividends.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ceva (Italy).—The Municipality of Ceva, Mondovi-Cuneo, invite offers for lighting the town by electricity. Address, Il Municipio di Ceva.

Saarbruck.—Tenders are invited by November 15 for the supply of 1,500 telegraph posts. Conditions, etc., for one mark from Die Eisenbahn-Telegrapheninspection, Saarbrücken, Germany.

Lisbon.—Tenders will be received up to November 13 for the supply of various spare electrical machinery, for the Portuguese Royal Railway Company. Conditions, etc., at Paris, rue de Châteaudun, 28.

Kassel.—The Fulda Canalisation Direction invite tenders for the supply of six automatic water-level indicators, with electric alarms. Pneumatic apparatus preferred. Particulars from and tenders to Das Hauptbauamt der Fuldakanalisirung in Kassel, Lutherstrasse 5, II.

Guernsey.—The Guernsey Railway Company, Limited, invite tenders for two electric motor bogie cars, with top transverse seats and reversible backs, to seat 80 persons, and suitable for the overhead wire system. Particulars can be obtained on application to the secretary, Guernsey.

Madrid.—The Director of Public Works invites tenders by November 15 for the concession of the construction and working of a tramway from Madrid to Colmenar Viejo, with branches to Chamartin and Rosa. Security, 12,505 pesetas. Particulars at the Direccion General de Obras Publicas (Ministerio de Fomento), Madrid.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Christiania.—The Secretary of State for Foreign Affairs has received information to the effect that the electrical works at Christiania require tenders for coal, either 2,000 tons best coal or 1,000 tons each of best gas coal and smokeless coal. Dates and conditions of delivery may be seen at the Commercial Department of the Foreign Office between the hours of 11 and 6, and further

Digitized by Google

details can be obtained at the office of the electrical works in Christiania, where tenders must be delivered before November 5.

RESULTS OF TENDERS.

Paris.—For the supply to the Direction Générale des Postes et des Télégraphes, Paris (accepted tenders) :—(1) 80,000 porcelain insulators : M. Defuisseaux, Baudour, Belgium, 40,624f. ; (2) 80 000 *id.* : Mme. Vve de Fenoyls, Ste-Foy-l'Argentière, Rhone, 40,680f.; (3) 150,000 insulators and 20,000 pieces for sheeted insulators : MM. Hache et Cie., Vierzon, Cher, 43,400f. ; (4) 32,000 cast-iron insulators : M. Letixerand, Persan-Beaumont, Seine-et-Oise, 15,360f.

BUSINESS NOTES.

Newcastle-on-Tyne.—The Corporation have finally decided on the cable system for the tramways.

River Plate.—The United River Plate Telephone Company have decided to extend its system to the town of San Martin.

Tokio.—Three petitions for permission to lay electric tramways in the city of Tokio are in the hands of the Japanese authorities.

Glansur, Limited.—This Company has been registered. Object : to carry on business as rubber manufacturers, cycle makers, metal founders, toolmakers, etc.

Indo-European Telegraph Company, Limited.—The directors have declared an interim dividend for the half-year ended June 30 at the rate of 5 per cent. per annum, tax free.

Oldham.—The minutes of the Electric Lighting Committee show that the Local Government Board have sanctioned the borrowing of £15,000 for electric lighting purposes.

Metropolitan Electric Supply Company, Limited.—The transfer register will be closed from to-day to the following Friday, both days inclusive, for payment of an interim dividend.

Rhyl.—A meeting of ratepayers has protested against the proposal of the Corporation to expend a sum of £20,000 on the building of tramways in the town, the motive power to be either gas or electricity.

Catalogues.—We have received from Messrs. J. Halden and Co., of Manchester and London, their new illustrated drawing-office catalogue of instruments, drawing papers, tracing papers, and photo papers.

Fulham.—The Electric Lighting Committee of the Vestry will hold a meeting on November 7 for the purpose of interviewing candidates for the post of adviser to the Vestry in the matter of electric lighting.

Bath.—The electric lighting company have applied for the consent of the Council to their application for a provisional order to extend their circuit of supply in the city, but the Council declined to grant it.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended October 27 amounted to £1,075, as compared with £901 in the corresponding week of last year, being an increase of £174.

Manchester.—It is proposed to ask the Board of Trade for an extension of the area of supply for electric lighting purposes and to let one portion of the work be regarded as compulsory and another part as permissive.

Compagnie de l'Industrie Electrique, Geneva.—The financial year 1894 95 closes with a loss of 192,000f. This, added to last year's loss of 276,000f., shows that the Company is behind to the extent of 468,000f. with a capital of 2 500,000f.

Budapester Strassenbahn Gesellschaft.—This Company has resolved, in order to cover the cost of the conversion of its horse tramways into electric tramways, which will be 10,660,000fl., to issue new debentures and shares to that amount.

Bristol.—It has been decided that telephonic communication between the haven-master's office at Shirehampton and the dock-master's office at Cumberland Basin shall be at once provided, and that the National Telephone Company shall do the work.

Light Railways in Cornwall.—A scheme for a light railway between Callington and Saltash, at the Devon end of Cornwall, is being talked of, to be worked by Great Western rolling stock. The estimated cost of the new line is between £50,000 and £60,000

Mica Product Syndicate, Limited.—This Company has been registered with a capital of £30,000 in £1 shares. Object : to enter into an agreement, made August 30, with H. Boyd for the acquisition of certain undescribed inventions, and to develop and turn to account the same.

The Eastern and South African Telegraph Company, Limited, notify that on Friday, November 15, at noon, at the company's offices, Winchester House, Old Broad-street, E.C., 381 5 per cent. mortgage debentures will be drawn for payment on January 1, 1896.

Theatre-Lighting.—The Lyric Theatre, Bath, and the Empire Theatre, Bristol, have been fitted throughout with the electric light by Messrs. Vaughan and Brown, Limited, of London, E.C. The same firm have also done all the gasfitting and hot-water work at the above.

Ramsgate.—The work of telephonically connecting the coast-guard station on the cliffs at Ramsgate with Ramsgate Harbour has been completed by the Government. The object is to enable information of disasters on the Goodwins to be more speedily communicated to Ramsgate tug and lifeboat.

Crewe.—The Town Council have received many complaints as to the inefficient character of the telephone service, and a resolution has been passed asking the company to improve the service, or the Corporation would consider the question of giving them notice to take up their poles from the streets.

City and South London Railway.—The returns for the week ended October 27 were £977, compared with £948 for the corresponding period of 1894, being an increase of £29. The total receipts for the half-year 1895 are £14,678, compared with £14,811 for the corresponding period of 1894, being a decrease of £133.

Stapleton (Glos.).—The Urban District Council have discussed the question of public lighting. It was urged by several members that the adoption of electricity in place of gas would be advantageous not only from the point of view of efficiency, but also of economy. It was ultimately decided to refer the consideration of the question to a special committee.

Aylesbury.—The Urban District Council have receive a report from committee recommending that the clerk should ascertain the mode of procedure necessary to obtain a license to light the public streets by electricity, and, after discussion, it was decided that a meeting of townspeople should be called for the purpose of taking into consideration a proposal of applying for a provisional order.

Western and Brazilian Telegraph Company.—The directors, after placing £7,876 to the debenture redemption fund and £5,000 to the reserve fund, propose a half-yearly dividend at the rate of £2. 10s. per cent. per annum, leaving £5,803 to be carried forward. This dividend will be payable as follows : 3s. 9d. per share to the ordinary shares and 3s. 9d. per share to the preferred ordinary shares.

Personal.—A presentation was made the other evening to Mr. J. A. Bell, of the Blackpool electricity works, on the occasion of his marriage to Miss Emma Smith. The gift took the form of an elaborate case of Sheffield cutlery, and an artistic testimonial signed by all the workmen in the place, the work of Mr. E. Slater, of the electricity works. Mr. John Hesketh made the presentation on behalf of the staff.

Bangor (N. W.).—A special meeting of the Bangor City Council has been called for the consideration of matters relative to the proposed introduction of the electric light into the town. One of the principal subjects under discussion will be the question of authorising Mr. Medhurst, the electrical engineer who is advising the Council, to proceed with the preparation of the plans, etc., in connection with the proposed scheme.

Londonderry.—The Lighting Committee have received the report of the resident electrical engineer (Mr. Christie), in which it was stated that the Harbour Commissioners had accepted the terms of the Corporation for the lighting of the cattle-pens with three electric lamps. The terms are 10 per cent. on the capital expended (estimated at £120), and 3d. per hour per lamp, or 9d. per hour in all. The cable is being specially made, and will be in Derry about November 5, and the lamps will be put up as soon as possible afterwards.

Bridlington.—A company has been formed for providing a promenade, gardens, concert and dancing hall, club, dining-rooms, etc. In addition, it is intended to lay out Hilderthorpe Lodge and grounds as strawberry and tea gardens, with athletic ground, bowling-green, etc. The whole of the gardens and buildings will be amply lighted by electricity and gas, after the style of the Spa at Scarborough. It is proposed to lay down electric tramways from Hilderthorpe Lodge to the railway station, and possibly to Flamborough.

Leicester.—The Town Council have discussed a report of the Gas and Electric Lighting Committee with respect to a memorial addressed to the Council by the electrical engineers of the town praying that the gas department should not carry on a fittings branch in opposition to private enterprise. The committee recommended that there be no alteration made in the present practice of the department, and it was denied that the committee canvassed for orders for the fittings, but when requested by customers to undertake the work they did so.

Akkumulatoren-Fabrik Aktien-Gesellschaft, Hagen.—The turnover for the past financial year has reached 4,880,000 marks, compared with 4,090,000 marks in the previous period; and the number of installations carried out has increased from 3,000 to 4,000. The most important installations were as follow: Germany, 13; Austria Hungary, 11; Switzerland, 6; Denmark, Sweden, Norway, Holland, North America, and Africa, one each. The net profit is 630,239 marks (1893-94, 629,113 marks), with which a dividend of 10 per cent., as in the previous period, will be paid.

Sheffield.—The following resolution has been passed by the Parliamentary Committee of the Corporation : "That, considering the great importance of the tramways question, this committee consider it undesirable that any report as to taking over and working the tramways by the Corporation should be presented to the Council until after the appointment of the new Parliamentary Committee on November 9 next, but that the town clerk be authorised to give the necessary parliamentary notices for acquiring powers to work the same, and for the construction of such additional lines as may hereafter be decided on."

Light Railways for Anglesey.—Mr. Lewis Hughes moved at the County Council meeting that the Government be approached with a view of ascertaining what assistance they could render towards constructing a light railway from Valley to Amlwch. He suggested that a small and influential committee be appointed to meet the

Digitized by Google

landowners of that district with a view to buying land on easy terms Both the last and present Governments had taken and were taking interest in light railways. Let the Council approach the present Government. Mr. Jones said that the committee, when appointed, should take the whole of the island into consideration. The motion was adopted.

London County Council.—The engineer having informed the Electrical Committee of the London County Council that he required additional assistance in consequence of the large amount of work at present devolving upon the electric lighting staff of his department, especially in connection with the inspection of electric light installations at theatres and music halls, the examination of proposals for loans to vestries and district boards for electric lighting works, and the lighting of the Blackwall tunnel, the committee have recommended that the engineer be authorised to engage the services of a temporary assistant for a period of three months at £3 3s. a week.

Edinburgh —Councillor Mackenzie, convener of the Electric Lighting Committee, believes that the electric light will be much cheaper than expected, because it is being taken more advantage of than was anticipated. Prof. Kennedy, in the report got from him in 1893, expected that within the first two years of the installation there would be from 20 000 to 25 000 8-c.p lamps on the system. The system is only six months old, and the Electric Lighting Committee have already got over 30,000 joined on. As the number is rapidly increasing, Councillor Mackenzie says the probability is that within the next year or two the charge of 6d. per Board of Trade unit will be reduced to 5d , if not less.

Cupar.—Mr. Gilmour (convener) has reported to the Fife County Council that the telephone company had agreed to pay to the county at the rate of £150 per annum, as from Martinmas, 1894, for poles and wires on the highways in the landward part of the county till January 1, 1896, when it is expected they would be taken over by the Post Office. The use of five instruments is to be continued for the county at £53 10s. per annum. Mr. Glass said, as a member of the Telephone Committee, that Mr. Haig, the convener, deserved the greatest credit for what he had done in the matter, and every member had worked earnestly to get the biggest possible payment that could be made to Fife from the telephone company, but they had been greatly misled.

The Central London Railway.—The work of constructing subways beneath the space opposite the Mansion House in connection with the new underground railway will shortly be commenced. The Bank of England authorities have requested that before these subways are commenced an examination of the foundations of the Bank at the corner of Princes street and Threadneedle street should be made. Arrangements are being made for sinking a shaft at this point, and in order that its construction may not interfere unduly with the pedestrian and vehicular traffic the work will be executed between the hours of 8 p.m. and 8 a m. Plans have been submitted, and will be carried into effect by Sir Benjamin Baker, Sir John Fowler, and Mr. J. H. Greathead.

Lancaster.—The Electricity Supply Committee have reported that Mr. A. S. Barnard had resigned his office of electrician to the Corporation, consequent upon his appointment to a similar office under the Corporation of Hull, and they had resolved that Mr. C. M. Johnson, assistant electrician, be appointed electrician at the electricity works on probation for a period of three months, at a salary of £100 per annum, he to perform such duties as the committee may from time to time determine, and to act under the instructions of the borough surveyor. On the report coming before the Council for confirmation it was suggested by the Mayor that, if at the end of the three months, the committee were satisfied with the appointment it would be a wise provision to make an agreement with Mr Johnson for a term of three years.

Fermoy.—The Town Commissioners have discussed with Mr. F. J. Warden-Stevens, A.M.I.C.E., of London, the practicability of lighting the town by electricity. Mr. Stevens said that he inspected the town and saw the water power available, and considered that Fermoy was admirably suited for electric lighting, and that the scheme would be profitable, giving increased light at less cost than that of gas. He advised the utilisation of water power, and thought that at least a thousand lights would be taken up by private consumers at present, the number of which would extend rapidly, and that one arc lamp of 1,500 c.p. would replace about four of the gas lamps and give a much better light. He advised the Board to apply to the Board of Trade for a provisional order. The Board decided to advertise for schemes and tenders from companies, and to submit them to Mr. Warden-Stevens.

Liverpool.—The Mersey Docks and Harbour Board give notice that the cable referred to in the notice to mariners, etc., of the 5th September last, by means of which electrical communication was to be established between the Formby lightship and the shore, has now been laid from the said lightship to a point near the Formby lifeboat house. The cable, after leaving the lightship, is laid towards Q 6 black can buoy, thence over Taylor's Bank and the Formby Channel to the southward of F 4 red conical buoy, to the point above mentioned. All masters, mates, pilots, fishermen, and others are cautioned not to anchor vessels or use trawls on or near the track of the cable. Mr. T L Miller, M.I.E.E., of Liverpool, has been asked to report to the Bootle Town Council on the electric lighting of the district, and to prepare estimates of the cost of plant and laying mains, with the necessary information as to working cost.

Devonport. — The Electric Lighting Sub-Committee have reported that they had had under consideration the notices received from the County of London and Brush Provincial Electric Lighting Committee and the Great Western Electric Light and Power Company of their intention to apply to the Board of Trade for provisional orders to supply electricity in the borough. Although the committee considered it would be expedient to defer any steps for the introduction of the electric light until more experience had been obtained, they were unanimously of the opinion that the control of such supply should be vested in the local authority, and therefore recommended the Council to authorise them to take such steps, if necessary, as they might advise for the promotion of an application to the Board of Trade for a provisional order during the ensuing session of Parliament. The report was adopted.

New Issue. — The London and Continental Investment Corporation, Limited, has been formed with a capital of £1,000,000, in 990,000 ordinary and 10,000 deferred shares of £1 each with the following objects: to acquire and hold any shares, stocks, bonds, debentures, or securities of any company, syndicate, or trust, and generally to act as finance and investment company; to prospect for, purchase, or acquire options over, develop, and work lands, concessions, mines, etc., and turn the same to account; to form and promote companies to take over such rights, and generally to act as an exploration and development company; and to construct and maintain railways, tramways, telegraph lines, gas, water, and electric works, etc. The first issue is of 500,000 ordinary and 10,000 deferred shares, and the whole of the issue of ordinary shares has been subscribed by and allotted to the signatories to the articles of association.

The Proposed Light Railway in Derbyshire.—The chairman of the provisional committee for the promotion of the light (electric) railway from Derby to Ashbourne has issued to the promoters a circular, in the course of which it is stated that "the scheme has been enthusiastically received by the Ashbourne farmers, and several gentlemen, thinking that it would benefit the agricultural community and promote local interests generally, have promised to subscribe towards the expenses of obtaining parliamentary powers, it being understood that in the event of the failure of the scheme any money beyond what is required for actual out-of-pocket expenses shall be returned to the subscribers ratably; but if the Bill is passed into law, and a company incorporated thereunder, £1 shares in such company shall be allotted to each subscriber for every £1 subscribed. Further support, however, is needed to justify the committee in proceeding with the application for the Bill."

Appointment Vacant.—The Ealing Urban District Council require an electrical engineer to superintend the whole of their electric lighting undertaking. His duties will be to take charge of the central electric station, transformer stations, and mains, and to superintend any future extension of mains. He must have had actual practical experience of alternating central-station work, and must devote the whole of his time to the duties of the appointment, and will be required to reside in Ealing within a reasonable distance of the central station. The system is high-tension alternating with transformer sub stations, and the street-lighting is high-tension continuous current. Applications, stating salary required (progressive), age, and previous experience, together with copies of not more than three testimonials of recent date, should be sent to Mr. William Ruston, clerk, Public Offices, Ealing, W., endorsed "Electrical Engineer," by 3 p.m. on November 6.

Birmingham.—As we intimated last week, it is proposed to try the overhead electric traction system upon the Nechells route should the necessary permission be given to the Central Tramways Company by the Birmingham City Council. The scheme, if sanctioned, will be carried out by Mr. Alfred Dickinson, engineer of the tramway company, who had charge of the introduction of the Walsall electric car system. To avoid the chief objection to the overhead system, it is suggested that the present lamp-posts upon one side of the road on the Nechells route shall be replaced by special posts, rising to about twice their height, and carrying the lamp at the middle of their elevation. The *Birmingham Post* says "Nechells is at present served by horse cars, but should the electric system be introduced and be found to give satisfaction, it would doubtless be proposed eventually for some or all of the other routes, upon which the ugly and otherwise offensive steam cars are at present tolerated only for the sake of the cheap means of locomotion they afford."

Stafford.—The Estates and Works Committee of the Town Council have recommended that an arc lamp be fixed in Market-square and that it—with the one in Gaol-square—be kept lighted at the expense of the electricity department to the end of the year, when, if the lighting prove satisfactory, the two lamps will be taken over by the Estates Committee at a cost of £22. 10s. per lamp, the requisities to be found by the department. The former recommendation was adopted; but the latter was referred to the Electricity Committee, it not being in accordance with the offer made by that committee. On the recommendation of the Gas and Electricity Committees, which in future will be amalgamated, the Council decided, in order to reduce the cost of raising steam for driving the machinery in the gas and electricity departments, to lay down a steam-main from the boiler-houses in the two departments at a cost of about £200, it being stated that this arrangement would enable the electricity department to do with two stokers. It was also decided to extend the electric lighting main as far as St. Paul's Church on Lichfield-road, at a cost of about £250.

Kingston-on-Thames.—The Lighting Committee have reported that the Native Guano Company had expressed their willingness

Digitized by Google

to pay for the lighting of the sewage works by electric light, to the same amount as the average sum paid for gas in the last four years—viz., £71. 15s. 8d. per annum—and to agree to any reasonable and workable arrangement to prevent waste or undue consumption of current. It was left to the chairman the town clerk, and the engineer to make the final arrangements on these lines. The committee have instructed the town clerk to enquire whether the gas company would reduce the price for street lighting, and also to ask their terms for lighting the lamps by incandescent gas burners. The electrical engineer was instructed to report as to the cost of lighting the road opposite Surbiton Park-terrace with electric incandescent light. The accounts of the committee showed a debit balance of £102. 11s. 5d. The estimate for the lighting rate showed a prospective outlay for the ensuing six months of £3,160. 7s. 5d., of which £1,117. 16s. was for lighting gas lamps. The sum expected to be received from consumers of the electric light is £1,175, leaving £1,985 7s. 5d. to be raised by a lighting rate. The committee recommended a rate of 4d. in the £. The report was agreed to by the Council.

The New Berlin Tariff.—The Berliner Elektricitätswerke have published their new tariff, according to which after January 1, 1896, the electric light will be obtained in Berlin on more reasonable terms. The cost is to be calculated on the basis of the kilowatt-hour as a unit, by which means the tariff becomes a simple one. The starting price for a kilowatt-hour amounts to 60 pfennige (7¼d., very nearly), so that the price of a 16-c.p. incandescent lamp will be 3 pfennige (·36d.) per hour, while the cost of a 100-c.p. arc lamp, including the cost of the carbons, comes to 3·5 pfennige (·42d.) per hour. For those consumers who undertake to see after and renew their lamps themselves the tariff begins at once. In future it is only proposed to charge them for the current consumed and the rent of the meter. In addition to maintaining the present allowances, the following deductions will be given to all yearly consumers for lighting purposes on the basis of the current taken during the year, as follows:

Up to 10,000 marks	....	5	per cent.
,, 20,000 ,,	....	7½	,,
,, 30,000 ,,	.....	10	,,
,, 40,000 ,,	....	12½	,,
,, 50,000 ,,	. .....	15	,,
,, 75,000 ,,	.....	17½	,,
Over 75,000 ,,	....	20	,,

Separate installations belonging to the same owner, and serving similar purposes, will be counted as one and enjoy a corresponding reduction on their total consumption.

Wolverhampton.—The Coseley District Council have held a meeting to consider the question of public lighting. In the course of the discussion the engineer remarked that it was possible to light up straggling districts with electricity, and it had been accomplished in several places satisfactorily and economically. Councillor Rolinson said every member of the Council was pledged to provide light of some kind, the question for discussion being which illuminant would be the best. They could not erect gas-works of their own, neither could they purchase from the Bilston Gas Company their rights, and if they could, in some of the most dangerous portions of the district there were no mains The Chairman (Mr. Clayton) said the estimated expense of providing and fixing gas lamps was really only an outlay of a few hundred pounds to begin with, while an electric installation to be of any use, and to provide for private consumers, meant an outlay of £12,000, which they would probably regret. He thought they should not land the district into a big expenditure right away. A motion was subsequently carried in favour of gas lighting. Colonel Ducat, inspector of the Local Government Board, has held an enquiry at the Town Hall relative to an application of the Corporation for power to borrow £5,000 for extending the electric lighting station. Mr. Brevitt (town clerk) explained that the Town Council had obtained tenders for laying down additional plant and cables for supplying other public thoroughfares with electricity, and the cost was estimated at £5,000. The Corporation could not take any more customers nor provide further street-lighting without additional plant. There was no opposition.

Tunbridge Wells.—Councillor Ashby Wood, who was down on the agenda of the last Ratepayers' Association meeting to introduce "Electricity as a Motive Power," said he proposed to deal with electric tramways, which were to them the most interesting phase of the subject and a matter peculiarly suitable for any municipal body to take up. Having quoted statistics to show the relative use of electric traction in the United Kingdom and abroad, he explained that the index to success with all these tramways was a quick and constant service The total cost of electric trams was about 4d to 6d. per car per mile, which was about half what horse trams cost, while they travelled at an average speed of nine miles an hour. Having dealt with the three principal systems which might be adopted, the speaker said he should like to see electric trams in some parts of Tunbridge Wells, and suggested that one service might very advantageously be put down Upper Grosvenor-road to the baths and recreation ground. They were spending nearly £4 a week in keeping up those gardens, and he should like to see them brought more within the reach of all the inhabitants. A service to Southborough would also be a great benefit, and he considered if they could only get such a means of transit it would very much increase and maintain the popularity of the town. They had now a central station and machinery capable of working a day load, and there was no reason why they should not have the comfort and convenience of these cars and at the same time make a profit to the ratepayers. Alderman Clifford said they did not offer that convenience to their visitors to see the beauty of the place which other towns did. The subject then dropped.

Plumstead.—The Works Committee have recommended the Vestry to oppose the application of the Woolwich Electric Light Company to the Board of Trade for a provisional order enabling them to extend their mains into Plumstead. Mr. Adshead moved that the recommendation be referred back to the committee. Mr. Harbour, in seconding, said the committee ought to give reasons for their recommendation. If their objection to the company's application was based on the idea that the Vestry would supply the electric light to the parish themselves, then he agreed that that was a good reason, but it should be stated. The Chairman said that that was the reason. Mr. Harbour continued that if the Vestry were not going to supply the light it would be a dog-in-the-manger policy to prevent this company from doing so. Mr. Harper, chairman of the Works Committee, said the reason for the recommendation was, as stated, that it might be thought advisable for the Vestry to supply the light and there would be no room for two sources. Mr. Swift supported the opposition to the company's application, and said it would be a waste of time to refer the recommendation back. He anticipated that the Works Committee would before long take steps to have the electric light in the parish, the Vestry undertaking the work. Mr. C. Coton said that if the Vestry were to allow the company to enter Plumstead they might hereafter, when they decided to manage the electric lighting themselves, find that they had to saddle themselves with a system which was obsolete and useless, as constant changes and improvements were being made in the mode of lighting. The recommendation of the committee to oppose the company's application was agreed to.

Coventry.—In the course of a few weeks, a correspondent writes, the Coventry and district tramways, unused for three years past, will be once more in working order, only under a system infinitely superior to the original steam equipment, which at last had to be abandoned. The headquarters of the new system of the Coventry Electric Tramways Company, Limited, are at Little Heath—the old depôt. The main building at Foleshill, erected by Mr. C Haywood, jun., is 104ft long by 50ft. broad, and under that roof are included the car-shed, 60ft. by 50ft., engine-room, 42ft by 33ft., and boiler-house, 42ft. by 16½ft. In the generating department are two of Browett and Lindley's 120-h.p. engines and two Westinghouse dynamos. Here, too, is the switchboard, with voltmeter, three ampere-meters, four switches, and a couple of rheostats. Trial trips of the trams were to be made this week, and a fortnight later it is hoped to have the line in regular working order. The overhead system is used, and that fact gives reason to hope that these 5½ miles of tramway between Coventry railway station and Bedworth will be remunerative enough to ensure their permanency for locomotive purposes. It is intended to give a 10 minutes' service between the electric station and Coventry, and a 20 minutes' one from Foleshill to Bedworth. Mr. Graff Baker is the managing director of the company who own the property, and Mr. H. O'Neill the secretary. The equipment of the line has been made by the General Tramways Company, of London; Mr. A. E. Winslow has acted as chief engineer; Mr. Fletcher is resident engineer, assisted by Mr. Pritt; and Mr. McMahon road constructor. The charge of the sheds at Foleshill will be with Mr. Wimshurst. When the staff leave here they proceed to Douglas to lay an electric tram along the Head Marine Drive.

Electric Lighting in India.—A correspondent writes to an Indian contemporary: "I have read your article about electric lighting in the city of Calcutta and have been attracted by your remarks on aerial cables. Such cables as you suggest may be seen in Bombay, where electric installations are more numerous than in any other part of India, and where a number of very interesting specimens of cables, suitable for various systems of distribution, are on view. There one firm has laid underground cables which have given no trouble whatever for several years One of the samples examined by me had a diameter of about 2in., and consisted of central copper strands thickly insulated with some special medium, impervious to water and unaffected by the highest ground temperatures On this covering was wound the core for the return current—a layer of copper wires again insulated like the central core. Over the insulation were pressed two tubes of special soft lead alloy with a thin intermediate layer of bituminous substance to render the inner sheath impervious to any water leakage through the outer. The lead was covered by another specially watertight textile preparation, over which two steel tapes were wound in such fashion as to completely protect the cable beneath. One or more coats of impregnated textile stuff completed the cable—the object of these being to prevent moisture from reaching the steel armour." Messrs. Bousted Bros. have been requested by the Colombo Municipality to put up an arc light in Prince-street outside the M M. Office, and another at the lampstand in York-street at the junction of Prince-street and Main-street, and this work will be carried out as soon as their electric main has been laid, while it is expected that the entire lighting of the fort will immediately follow. Messrs Bousted Bros. are putting up the accumulators to better regulate the supply of electricity to the post office and the Queen's House. They expect to receive shortly the plant requisite for connecting the Bristol with the main, as part of it has already been shipped and the rest is to follow quickly.

Leeds.—The Tramways Committee of the Leeds Corporation have met to take steps with the object of carrying into effect the recent resolution of the City Council in regard to electric traction. In the course of a discussion, extending over two hours, various suggestions were made, and eventually it was decided to seek the advice of Dr. Hopkinson. Dr. Hopkinson is to visit Leeds and

Digitized by Google

advise the committee as to the feasibility of working a service of cars by electricity, from the Canal Gardens in Roundhay Park *vid* North-street, Briggate, Boar-lane, Wellington-street, and Kirkstall-road, to Kirkstall. The idea of the committee is to extend the existing overhead wires from their present terminus opposite the Roundhay Post Office to the Canal Gardens, thus completing this section from the park to Sheepscar. The requisite wires are then to be carried longitudinally along a line of posts or standards down the centre of North-street, New Briggate, and Briggate, to the junction of the latter avenue with Boar-lane. From this point to the Queen's Hotel an experiment of the conduit system is to be made by laying the wires underground, and from the Queen's to Kirkstall they are to be suspended, as in Briggate, on a single row of posts along the centre of the road. No wires are to cross the thoroughfares anywhere between Sheepscar and the Kirkstall terminus, and all the streets and roads *en route* are to be illuminated by arc or other lamps attached to the posts or wires, as may be found most practicable. Details as to what the committee may wish to do with the existing plant of the Roundhay Park electric car system was not settled. Whether they may desire to take over any or all of the cars, wires, and generating machinery now in operation will depend to some extent upon the report of the authority mentioned. Dr. Hopkinson is to advise as to where he thinks power for the experiment might most advantageously be generated, and in making recommendations he is to have regard to the fact that the City Council have pronounced an opinion in favour of electricity on the overhead method.

British Electrical Manufacturing and Engineering Company.—We have received a copy of the prospectus of this Company, which has been formed, with a capital of £20,000 in 4,000 shares of £5 each, for the purpose of purchasing as going concerns, amalgamating, and carrying on (1) the goodwill, plant, machinery, stock-in-trade, etc., of the manufacturing department of the business of Messrs Laing, Wharton, and Down, electrical engineers and contractors, of New Bond-street, W.; (2) the goodwill, plant, machinery, stock-in-trade, etc., of the St. Martin's Electrical Manufacturing Company, Limited of Hammersmith, London, W. The Company will carry on the business of general electrical engineers in its various branches, but more particularly as manufacturers of all articles appertaining to electrical engineering, and will acquire from Messrs. Laing, Wharton, and Down a lease for the remainder of their term of that portion of their workshops in Haunch of Venison Yard, Piccadilly (rebuilt about four years ago and used for the manufacturing business), at the rent of £150 per annum, to include rates and taxes. Messrs. Laing, Wharton, and Down have, we understand, entered into a contract binding themselves not to engage in business as manufacturers of similar goods to those hitherto produced, nor will they manufacture for their own purposes, but will give the Company the orders for all such goods as they may require. The St Martin's Electrical Manufacturing Company, Limited, was incorporated with the primary objects of retaining and developing the connection of Mr. T. Duncan Dundas, the well-known electrical engineer, and from the commencement has been a signal success; many valuable contracts for the War Office, the Brush Company, Crompton and Co., and other well-known firms have been carried out, and at the present time it is stated that far more work and contracts are in hand than the limited capital allows it to properly cope with. The Company have secured the services of Mr. C. L Baker, M I E.E., as consulting engineer. Mr. Baker was the founder, and subsequently the managing director, of Chas L. Baker and Co, Limited, of Cornbrook Telegraph Works, Manchester.

Metropolitan Asylums Board.—The Local Government Board have sanctioned the placing of a contract with Callender's Bitumen Telegraph and Waterproof Company, Limited, to supply and lay electric light cables at the hospital ships, at an estimated cost of £125, without advertising for sealed tenders. The Brook Hospital Committee brought up the following report, which was at once agreed to: "We beg to report that in accordance with the authority given us on May 11, 1895, Prof. A. B. W. Kennedy, LL D., F.R.S., has been instructed to prepare plans and specification for the installation of the electric lighting of the Brook Hospital, and we now submit for the managers' consideration the plans and specification which he has prepared. Prof. Kennedy advises that tenders for the engines, dynamos switchboards, and batteries should be obtained from a selected list of firms, but that the remainder of the work, such as wiring, etc., may be put to public tender. We concur in the opinion expressed by Prof. Kennedy, and we submit the following list of names of firms, as advised by him, from whom we recommend tenders should be obtained—viz.: Messrs. Siemens Bros. Woolwich; Messrs. Crompton and Co., Chelmsford; Messrs. Johnson and Phillips, Charlton; Messrs. J. H. Holmes and Co., Newcastle-on-Tyne; Messrs. Thos. Parker, Limited, Wolverhampton; Messrs British Thomson-Houston, Limited, Westminster; Messrs. W. H Allen, Son, and Co., Bedford; Messrs. Mather and Platt, Salford; Messrs. Davey, Paxman, and Co., Colchester; Messrs. Robey and Co., Limited, Lincoln; Messrs. Marshall and Sons, Limited, Gainsborough; the Electric Construction Company, Wolverhampton. We recommend (*a*) that tenders be invited from the list of firms referred to in the report of the Brook Hospital Committee for the dynamos, batteries, switchboards, and engines for the electric light installation of that hospital; (*b*) that the Brook Hospital Committee be empowered to issue advertisements inviting tenders for the remainder of the work (wiring, etc.) connected with the installation of the electric light of that hospital and the adjoining ambulance station." The Ambulance Committee reported as follows: "In accordance with the intimation given in our report of July 20 last, we now submit a specification, prepared by Prof. Kennedy, for the wiring of the Brook Ambulance Station, and for the supply and fixing of all fittings, etc, necessary for lighting it by electricity. The cost of the work is approximately estimated by Prof. Kennedy at £300. In our opinion it will be of advantage if this work could be carried out by the contractor who will be employed to execute similar work in the adjoining Brook Hospital. We therefore recommend (*a*) that the specification for wiring, etc., the Brook Ambulance Station be included, but at a separate price, in the contract for the execution of similar work at the Brook Hospital; (*b*) that for preparing the specification, and supervising the execution of the work, Prof. Kennedy be paid a commission of 5 per cent. on the cost thereof." This was agreed to.

Proposed Electric Tramway between Fleetwood and Blackpool.—This scheme has been approved. The Fleetwood Urban Council held a special meeting on Monday to receive and consider correspondence in connection with the proposed application for powers to construct tramways in the district. The promoting company propose to construct a double line of tramways on the overhead electrical system from Blackpool to Fleetwood, commencing at Talbot-road Station, running thence along Dickson and Warbrick roads to the Gynn, thence along the cliffs to Norbreck and Little Bispham, leaving the cliffs at Anchorsholme, thence following the highway to Rossall, thence across the fields to Flakefleet to a straight line, being a continuation of the Copse-road, following the north-west side of that road to West-street, up North Albert street to North Euston Barracks. Owing to the recent attitude taken up against the Blackpool Corporation by certain of the ratepayers in reference to the purchase of the Gynn Estate, it is very probable that the tramways in the borough will be postponed to another season, but at the same time, provided the promoters can get a satisfactory agreement with the Blackpool Corporation, they will in the first instance make the tramway from the borough boundary to Norbreck This can be done without either Act of Parliament or provisional order. If, however, satisfactory arrangements and assistance can be got from the Fleetwood people, the Local Board, and the large landowners on the route, the promoters will go for a Bill this session and make the tramway from Blackpool to Fleetwood; if not, the tramway will stop at Norbreck. The company asked for the assistance of the Council, authorising by resolution the making of the tramways in their district, and for the erection of an electrical station for creating power to drive the tramway cars. The following resolution was unanimously carried: "That the proposed applications for powers to construct and work tramways within this district, as per letter now read from Mr. B. Sykes C.E., be approved, subject to the plans and working details being approved when ready, and also subject to the draft provisional order or Bill being satisfactory in all respects to this Council."

Willesden.—Mr. O Claude Robson, engineer and surveyor to the Willesden District Council, has issued the twentieth annual report of the Council for the year ended March 31, 1895. In it he says: "A suggestion has been made by the Hampstead authorities to supply electric lighting to the High-road, subject to a moiety of the cost being defrayed by the Willesden District Council. The amount of such moiety, however, was so excessive that the offer could not be entertained. Independently, however, of the cost involved, it is a point for consideration whether it would be possible for Hampstead to supply outside their boundaries without obtaining special powers for same. It is also doubtful if it would be a wise policy for Willesden to forego any possible benefit that might hereafter be derived from electric lighting to premises in the High-road, should the District Council themselves obtain a provisional order in the future for electric light within their district. When the time does arrive for adoption of electric lighting, it is strongly advisable that all supply should be controlled by the Council rather than be in the hands of a neighbouring authority or private company. Should the suggestion, therefore, of the Hampstead authorities be entertained, I would recommend that it be subject to a terminable agreement, and that any future powers that may be obtained by the District Council should be safeguarded, Telephonic communication is provided at the Kilburn fire station Salusbury-road, to the following localities—viz., Public Offices; fire-escape, Storeyard; police station, Kilburn; turncock, Kilburn; isolation hospital, Neasden; sewage works, Neasden; fire station, Harlesden; medical officer, Harlesden; police station, Harlesden; turncock, Harlesden. The whole of the above communication is the property of the Council the work having been carried out by the late Local Board. The former contract with the General Post Office for an annual rental for telephonic service between the police station and the Harlesden fire brigade station has been cancelled. The price formerly paid to the General Post Office for the service before mentioned was £26. 15s per annum, whilst the sinking fund of the loan for the entire work recently carried out by the Local Board, together with maintenance, will represent but £64. 6s 9d. per annum, notwithstanding this work provides treble the communicating length that was included in the contract with the General Post Office, and also includes all wires and apparatus connected with the communication to hospital, sewage farm, offices, etc. The wires are partly conveyed by iron poles along highways, and partly by attachments to houses, but I am glad to report that I was able to obtain easements in every case without any pecuniary compensation or yearly rental. The total length is about 3¾ miles, and the entire cost has amounted to £111. 6s. 11d. The work was carried out by Mr. F. E. Stuart, of Ealing, who maintains the whole of the wires and appliances for the sum of £25 per annum. A portion only of both capital

Digitized by Google

and annual cost is allocated to fire brigade expenditure, as a large amount of the work was connected with the isolation hospital. Two additional alarm posts have been fixed, making a total of 10 now provided throughout the district. The whole of the foregoing posts are supplied and fixed by the General Post Office, who charge a rental of £137. 10s. for the entire system, which represents an average sum of £13 15s per post. With regard to the post at Willesden Green, adjacent to the sub-station at Poplars-avenue, it is most desirable that this should be connected by telephone with the central station in Salusbury-road in a similar manner tc the new sub-station in Dyne-road. The whole of the call-bells and wires formerly con necting the volunteers' residences with the old station in Bridge-street, Kilburn, were removed and utilised as far as possible in the provision of elec'rical calls to the men's quarters at the new station. The system of electrical call still, however, exists at Harlesden, where the houses of the volunteers are connected with the fire brigade station in High-street."

Cork.—Mr. T. W. Smith, of Messrs. Calvert and Co., of Manchester, has submitted to the Town Council of Cork his report on the proposed electric lighting of the city. He advocates the adoption of the low-tension system. For comparison, he has drawn out two distinct schemes—one for public lighting, the other for the necessary plant and mains for lighting the shops, offices, warehouses, etc. Public lighting.—For efficient lighting of the streets he has suggested about 100 arc lamps, each of a nominal 2,000 c.p., fixed on cast-iron pillars about 50 yards apart, arranging them in the centre of the wide streets, and alternating them on either side of the narrow streets. He estimates the cost of this scheme, including duplicate plant in case of breakdown, at approximately £8,000, which is made up as follows: cable and laying, £2,100; 100 arc lamps erected, £2,500; buildings, say, £250; 200 h.p. engines, £920; two boilers, £850; two dynamos, £800; switchboard and instruments, £150—total, £7,570, or, in round figures, £8,000. The annual cost of maintenance of this station would be approximately £2,000, made up as follows: coal, calculated at 2½lb. per horse-power per hour, engines working all night, at 15s. per ton, £200; 3½ per cent. interest on £8,000, £280; 5 per cent. depreciation, £400; carbons, £200; two enginemen, £200; two firemen, £100; two trimmers, £80; resident engineer, £200; oil and sundries, £70—total, £1,730, or in round numbers, £2,000. Alternative scheme.—In drawing out an alternative scheme for incandescent lighting—that is, for plant and mains to supply consumers—he has included heavy mains to certain points of the city, from which any after extensions can be taken at very little cost. He has also included mains large enough to admit of the public lights being taken off the same wires as the consumers', and has quoted a price for a system suitable for electric lighting. He estimates the cost of this scheme, which includes plant for 100 arc lamps, plant and mains for 5,000 8-c.p. incandescent lamps, and mains for an extension of 10,000 more 8-c.p. lamps, or the equivalent of same, to be approximately £20,000, made up as follows: cable and laying, £7,000; one 200-h p. and two 100-h.p. engines, £1,500; three 150-h.p. boilers, £1,725; three dynamos, £1,300; buildings, £250; fixing engines, £500; mason's work, £500; meters and house connections, £1,000; switchboard, etc., £500; arc lamps and fixing, £2,500—total, £16 775; or, in round figures, £20,000. The cost of running this plant per annum he estimates to be £3,000 made up as follows: 350 h p (or the power required for 5,000 8-c.p. lamps and all the public lighting) to run from dusk to 9 p.m., or approximately 1,000 hours per annum: coal account, £220; 100 h.p., or the power required to run the public lights only from 9 p.m. to daylight cost account, £100; 3 per cent. interest on £20,000, £600; 5 per cent. depreciation, £1,000; labour, two men at £100 per annum, £200; six men at £50 per annum, £300; engineer, £300; repairs and sundries, £200—£2,920, or, in round figures, £3,000. With reference to the public lighting, this estimate is a liberal one, as, no doubt, arrangements could be made to put out a certain number of lamps, say, at 12 p.m., and thereby reduce the cost of upkeep. In estimating the prospective revenue, he is assuming that the 5 000 8-c.p. lamps, or their equivalent in 16-c.p. or arc lamps, would be taken up by the various residents on the mains, and that one unit of current will supply 40 lamps for one hour. We have, therefore, 125,000 units per annum sold, which, at the small sum of 6d. per unit, would bring in a revenue of £3,125 per annum. This being exclusive of the public lamps we have maintained free, and a profit of. say, £125 in cash. Again, this profit is exclusive of any revenue which might be derived from the sale of current in the daytime for traction work, etc. In conclusion, he has prepared a rough plan showing the area proposed in this scheme, and would suggest that before lightly selling the provisional order to any private company a deputation be sent to enquire more fully from stations working on the proposed system what their views are. The committee report on this: "Without committing themselves to the various details of either scheme, your committee are, however, of opinion that sufficient has been shown by the report under consideration to warrant them in recommending, and they do accordingly recommend, the Council to authorise the town clerk to take all necessary steps to obtain for the Corporation a provisional order enabling them to borrow money, erect works, provide and work all necessary plant, machinery, etc, for the production, storing, distribution, and sale of electrical energy, for all public and private purposes, within the compulsory area defined by Mr. Smith's report, or such modification or extension thereof as the Corporation may meanwhile determine; and also, at the option of the Corporation, within such larger area, not exceeding three miles from the borough boundary, as the Council may in like manner determine and the provisional order define. When the Corporation shall have obtained the provisional order above referred to, it will then be open to them to consider whether they should themselves exercise the powers thereby to be conferred, or contract with some company duly authorised, to carry out the work of electrical supply for public or private purposes, or for both, as may be determined, and on such terms, conditions, and powers of resumption as may be agreed upon between the Corporation and such company. As a corollary to the foregoing recommendation, your committee further recommend that the Corporation dissent from the applications proposed to be made for provisional orders by the Cork Gas Consumers' Company, the Cork Electric Light and Power Company, Limited, and Mr. Edward Felton on behalf of a company to be formed, respectively, and of which notice has been severally given to the Corporation." The Council have adopted the report.

Cardiff—Mr. W. J. B. Clerke, M.I.C.E, the inspector appointed for the purpose, has held an enquiry into the application of the County Council of the borough of Cardiff to the Local Government Board for sanction to borrow £12,885 for purposes of electric lighting, £1,576 for the improvement of Roath Park, £500 for the purpose of public lighting, and £200 for laying out Windsor Esplanade Gardens. The Mayor (Alderman P. W. Carey) and the Borough Engineer (Mr. W. Harpur) gave evidence in regard to the item of £12,885, his Worship stating that the compulsory area was now lit; £5 385 of this sum was for extensions in Newport-road, Castle-road, West grove, Charles-street, Bute street, Guildford-crescent, Park-place, Corbett-road, Royal and High-street arcades, and Trinity-street, as well as the erection of a testing-room. The remaining £6.500 was for defraying the excess of expenditure over capital already borrowed and for other purposes. Mr. S. Walker, electrical engineer, criticised in certain particulars the Cardiff electric lighting scheme, and alleged that the expenditure was greatly in excess of what it should have been. Mr. Harpur was confident the scheme would pay. Mr. Massey, Corporation electrical engineer, said the applications were increasing at a phenomenal rate. Mr. Harpur: For the last two months they have equalled nearly 1,000 lamps per month. Mr. Walker: What is the capacity of the maximum load? Mr. Harpur: Between 8,000 and 10,000. Mr. Walker knew as a fact that mains had been laid a second time, in one case starting a leak big enough to light an eight-candle lamp. Mr. Massey: That is not so. Mr. Harpur: It is absolutely false. Mr. Walker: I tested it myself. Mr. Walker next asked if any portion of the money was for the lighting of the market and Town Hall. The Inspector: It is not mentioned in the figures before me. Mr. Harpur said he had given all reasonable information to Mr. Walker, who was absolutely wrong in the statements he had made. Mr. Walker: What are the facts of the Town Hall and market hall lighting? The Inspector: That cannot be entered into at this enquiry. We cannot go into irrelevant matters. Mr. Harpur said that Mr. Walker's tender for the work was double £500; so that if it cost £600 or £700, surely it was a cheap job. Mr. Walker insisted that it was a public matter, and said he didn't want the contract if that was any information to Mr. Harpur. Mr. Harpur: You were anxious to tender, at any rate. Mr. Walker: No, I was not. I tendered as I tender for everything else. Mr. Harpur informed Mr. Walker that in reference to the Town Hall and the market they had two contracts—one for the wiring and the other for supplying the fittings. Mr. Walker wanted to put those accounts together. Mr. Walker then said if Mr. Harpur had given him information there would have been less trouble in the public Press The Town Clerk (Mr. J. L. Wheatley) remarked that if Mr. Walker had applied to Mr. Harpur he would have been furnished with all particulars, and saved himself a lot of trouble. Mr. Walker next asked if he could not get into the electric lighting station. The Town Clerk: Make the application, and you will have an official answer. Mr. Harpur: I have not refused admission to Mr. Walker or any other person. Mr. Walker: I have been refused. The Town Clerk: There is always a right way and a wrong way. Make a written application, and it will be received with every courtesy. Will that satisfy you? Mr. Walker: It will satisfy me now. The Lighting and Electrical Committee recommended on Monday that the rectifiers be removed from the Town Hall to the central station at Canton, at an estimated cost of £700 or £750, as such removal will effect a saving in wages of about £175 per annum. Councillor Riches pointed out that the recommendation was on all fours with his own contention at the very outset of the project. It was reported that the borough engineer considered that the installation of the electric light was now completed so far as the compulsory area was concerned. The Mayor explained that the placing of the rectifiers in the Town Hall meant a saving at the time of the cost of laying the necessary mains between Canton and the Town Hall, so that their removal really meant no additional cost. Having the rectifiers at the central station would enable three men having charge of them to do work in other departments also. Applications for installations were coming in in a very satisfactory manner, and he hoped that 12 months hence the electric light at Cardiff would prove not only a public boon but a paying concern. The borough engineer was instructed to start a day load forthwith. Mr. Massey, the late consulting engineer, has offered to be a member of the deputation to confer with the Local Government Board on the subject of electric lighting, at no expense to the ratepayers. The Electrical Committee, however, decided that Mr. Appleby, the chief electrical engineer at Canton, was the proper person to accompany the mayor, the town clerk, and the borough engineer. A deputation from the Machinery and Lighting Committee of the Cardiff Exhibition asked the committee to assist them in the lighting of the exhibition. It was stated that the probable number of lamps required

Digitized by Google

would be about 1,200 incandescent, of 15 c.p., and 200 arc lights. After conference with the engineers it was announced that this amount of lighting was equal to half the amount now created at Canton, and that to supply the lamps required the town would be put to an expenditure of at least £10,000. Eventually it was agreed that the Mayor, Alderman Jacobs, and Councillor Evans be selected to meet a sub-committee of the Exhibition Lighting Committee, an understanding being arrived at that, it being impracticable for the town to supply the energy, the exhibition promoters should lay down an installation plant of most recent type, to be approved by the borough and electrical engineer, so that it could be utilised by the town afterwards.

PROVISIONAL PATENTS, 1895.

OCTOBER 21.

19734. **Improved means or apparatus for electrically igniting petroleum and other like motors.** Count Albert de Dion and Charles Bouton, 78, Fleet street, London.

19745. **Improvements in and in the manufacture of plates for electric accumulators or secondary batteries.** Johannes Körner, 6, Lord-street, Liverpool.

OCTOBER 22.

19815. **An electromagnetic apparatus for actuating railway brakes and switches** Charles Melbourne White, 27, Southampton-buildings, Chancery-lane, London. (The St. Louis Brake Company, United States). (Complete specification.)

19828. **Improvements in electrolytical apparatus.** Richard Heathfield and William Stepney Rawson, 28, Southampton-buildings, Chancery-lane, London.

19832. **Improvements in connection with electric propulsion.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

19833. **Improvements in connection with the electrical propulsion of vehicles.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

19837. **Improvements in electric arc lamps.** Thomas Edgar Adams, 18, Buckingham-street, Strand, London. (Complete specification)

19838. **Improvements in electric arc lamps.** Thomas Edgar Adams, 18, Buckingham-street, Strand, London. (Complete specification)

19839. **Improvements in dynamo generators or motors.** Albert de Puydt and Maximilien Poncin, 60, Queen Victoria street, London. (Complete specification.)

19860. **Improvements in regulating electric motors.** James Devonshire, 70, Chancery-lane, London (William B. Potter, United States) (Complete specification)

19861. **Improvements in three-wire electric railways.** James Devonshire 70, Chancery-lane, London. (William B. Potter, United States). (Complete specification.)

19862. **Improvements in dynamo-electric machines.** James Devonshire, 70, Chancery-lane, London. (Elihu Thomson, United States). (Complete specification)

19863. **Improvements in regulators for alternating currents.** James Devonshire, 70, Chancery-lane, London. (Charles P. Steinmetz, United States). (Complete specification.)

OCTOBER 23.

19925. **An automatic cut-off for atmospheric gas-burners and electrical heating stoves.** Charles Goodwin Norton, 38, Marchmont-street, Russell-square, London.

19947. **Improvements in electric contact devices.** Carl Moradelli, 323, High Holborn, London. (Complete specification.)

19973. **Improvements in or connected with electric lamps.** William James Davy, 40, Chancery-lane, London.

OCTOBER 24.

19989. **An electrical "tell tale" or watchman's recorder.** John William Fletcher, The Homestead, Cale Green, Stockport.

19992. **Improvements in the method of laying an electric cable for tramways or railways and in the means of communication between the conductor and the car.** Crawford Barlow, 154, St. Vincent-street, Glasgow.

20028. **Improvements in the brushes of dynamos.** Frederick John Chaplin and Robert Chaplin, 77, Colmore-row, Birmingham.

20047. **An improvement in the caps of incandescent electric lamps.** The Edison and Swan United Electric Light Company, Limited, and Arthur Woodley, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

20048. **Improvements in or pertaining to electrically-driven pumping apparatus.** Francis Edward Elmore, the Old Hall, Knostrop, Leeds.

20071. **Improvements relating to electric railways.** Alfred Philippi, 18, Southampton-buildings, Chancery-lane, London.

20073. **Improved means to be employed in the production of sheets or strips or equivalent forms of metal by electro-deposition.** Sherrard Osborne Cowper-Coles, 47, Lincoln's-inn-fields, London.

OCTOBER 25.

20131. **An improved manufacture of secondary or storage battery plates.** Paul Opitz and Wilhelm Petschel, 45, Southampton-buildings, Chancery-lane, London.

20132. **Improvements in generating gases or steam by electricity from water, oil, or other suitable material.** John Henrique Dunn and John Parsons, Saville House, Wood Green, London.

20164. **Improvements in or connected with the production of metal in sheets or other form direct from zinc ores, applicable in part for use in the electrolytical deposit of metals generally.** Sherrard Osborne Cowper-Coles, Maurice Ulcoq, Walter Murray Guthrie, and Carrington Riddell Gordon Smythe, 47, Lincoln's-inn-fields, London.

OCTOBER 26.

20214. **Improvements in tubular galvanic batteries.** Edward Stanley Boynton, Prince's-chambers, Wolverhampton. (Complete specification.)

20215. **Improvements in double-fluid galvanic batteries.** Edward Stanley Boynton, Prince's chambers, Wolverhampton. (Complete specification.)

20216. **Improvements in galvanic batteries.** Edward Stanley Boynton Prince's chambers, Wolverhampton. (Complete specification)

20237. **An improvement in electric safety fuses.** The Edison and Swan United Electric Light Company, Limited, and Charles Faraday Proctor, 28, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

NOTES.

African Natives and Telegraphy.—A correspondent says that the telegraph in Central Africa will in time be worked entirely by natives, who are wonderfully quick at learning the system. Their keen eyesight makes them especially proficient in heliographic work.

Light Railways.—Mr. Ritchie, the President of the Board of Trade, accompanied by the Earl of Dudley and Sir C. Boyle, the parliamentary and permanent secretaries of that Department, left London last Friday on a short visit to Belgium and France, for the purpose of seeing certain of the light railways in operation in those countries. Mr. Ritchie intended to return to town to-morrow.

Cheap Telegraphy.—It may be remembered that cheaper telegraphy to Australia was introduced by the Governments of Colonies guaranteeing the cable companies against a portion of the loss. In last year, ending with April, the heavy traffic through gold-mining led to the receipts rising above the guaranteed sum. Hence, the Colonies get cheaper telegraphy without cost after three years of small contributions.

Royalty Patronises Electricity in Austria.—Considerable prominence is given in the new number (November 1) of the *Zeitschrift für Elektrotechnik* to the fact that "His Imperial and Royal Highness the Most Serene Herr Archduke Carl Ludwig has been graciously pleased to undertake the patronage of the Elektrotechnischer Verein in Vienna." The Archduke makes the announcement in a letter in which he dwells upon the importance and the great development of electrical engineering.

Glucinum.—The metal glucinum, hitherto a chemical rarity, is likely to come forward as a useful material, especially in electrical work. It is only twice as heavy as water, and is therefore even lighter than aluminium. It is a good deal less extensible than iron, and it has an electric conductivity nearly equal to that of silver, greater than that of copper. It is more durable than iron. At its present price, 71s. 4d. per pound, it is one-tenth the price of platinum, weight for weight, and 1-160th the price, volume for volume.

Institution of Electrical Engineers.—The Institution of Civil Engineers have kindly consented to permit the meetings of the Institution of Electrical Engineers to be held in the new building of the former institution, but as there is some doubt as to whether the building will be sufficiently advanced to allow of the use of its lecture hall on the 14th inst., the Council of the Institution of Electrical Engineers have decided to postpone the opening of their session until the 28th inst. The annual dinner of the Institution will take at the Freemasons' Tavern on Friday, the 29th inst.

Electric Traction for Army Purposes.—M. H. Maigne has called attention to the facilities which would be afforded for mobilisation and the transport of army supplies if some system of electric traction were provided on the canals leading to the frontiers. *L'Eclairage Electrique* of October 26, after remarking on the superiority of water transit for the removal of the wounded, says that the canals leading to the eastern frontier of France would be able to take the heavy transport of five army corps, and considers the question worthy of the attention of the military authorities.

Heriot-Watt College, Edinburgh.—The professorship of applied physics and electrical engineering having become vacant by the appointment of Prof. Mullineux Walmsley to be principal of the Northampton Institute, Clerkenwell, London, the Governors of the Heriot-Watt College announce that they will be glad to receive applications from candidates for the appointment. The new professor will commence duty on January 1, 1896. Applications, accompanied by 30 copies of testimonials, should be sent to Mr. David Lewis, treasurer, 20, York-place, Edinburgh, before 22nd inst. The salary attached to the professorship is £400 per annum.

Flywheel Accidents.—Just a few hours before the recent fatal flywheel accident at Hoboken a 15ft. wheel burst at the station of the Homestead (Penn.) Electric Light and Power Company, instantly killing the engineer. The plant was damaged to the extent of 2,500dol. Pieces of the wheel tore through the sheet-iron roof and demolished the floor, and one fragment went through a 3ft. brick wall. A large piece was thrown high in the air and fell into a neighbouring newspaper office, causing a loss of 500dol. The plant had not been operated for three weeks before the accident occurred, and it will take two weeks to repair the damage, during which time the station will be shut down.

"Holding Up" a Trolley Car.—Five armed and masked men "held up" a trolley car of the North Shore Electric Street Railway Company near Berwin-avenue, between Chicago and the suburb of Evanston, one night recently, cut the wire, thus preventing assistance from following cars, and putting out the lights, and then robbed the 18 passengers of their money and valuables. A passenger named T. P. Nesbitt, of Evanston, drew his revolver, but it was knocked from his hand by one of the robbers and discharged, the bullet striking Nesbitt in the leg. The conductor saved his money by dropping it down between the walls of the car and the window openings. The robbers, of course, escaped.

Electricity and Tadpoles.—Some curious experiments on tadpoles are described in a lecture by Dr. A. D. Waller, published in the current issue of *Science Progress*. A cell fitted with suitable electrodes and filled with water in which one or more tadpoles were placed, was traversed by an electric current. If the direction of the current was such as to pass from head to tail, the tadpole waggled his tail; but if passed in the other direction he lay quiescent. A large trough in which a number of tadpoles were swimming about in all directions was also traversed by the current, which excited great commotion among its occupants for a few moments, but finally the whole of them came to rest with heads and tails lying in line with the direction of the current.

The Spectra of Carbon Electrodes.—Mr. W. Noel Hartley contributes a reply to Herren Eder and Valenta's criticisms on a previous paper by Messrs. Hartley and Adeney. The author still thinks that the lines with the wave-lengths 3881·9, 3870·7, 3589·9, 3584·8 are carbon lines, and not the edges of cyanogen bands, as Herren Eder and Valenta state. These same lines are obtained from the combustion of cyanogen and from carbon electrodes surrounded by saline solutions, but are not given by cyanides. A list is given of the lines which appear under different circumstances when condensed sparks are passed between graphite electrodes. This list includes the lines of dry electrodes in air, in carbonic anhydride, and in oxygen.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on the 4th inst., Sir James Crichton-Browne presiding. The following were elected members: H.R.H. Prince Louis Philippe, Duc d'Orleans, Sir John Evans, K.C.B., F.R.S., the Hon. Adrian Verney Verney-Cave, Mr. Walter Allcroft, and Mr. James Beale. The managers reported that the late Mr. John Bell Sedgwick, M.R.I., had bequeathed £300 to the Royal Institution in aid of the fund for the

Digitized by Google

promotion of experimental research at low temperatures. The special thanks of the members were returned to Sir Frederick Abel, Bart., for his donation of £50 to the fund for the promotion of experimental research at low temperatures.

A House Railway.—There are rumours that the well-known entertainer, Mr. George Grossmith, intends to convert his house railway, popularly known as the Dorset-square Railway, into an electrical line, he having been smitten with the charms and possibilities of the subtle current. The railway, it seems, runs through his residence from the main terminus, the reception-room, through the hall to the stables, the other terminus being the coach-house. The present steam-engine is 3ft. high, and is capable of attaining a comparatively high rate of speed. The whole plant complete originally cost about £500. It is stated that one of the most humorous sights imaginable is to watch Mr. Grossmith as, seated in the tender in company with one or two juvenile friends, he starts the train, peering anxiously in front in order to avoid any possible accident, turning on and shutting off steam as occasion requires, and invariably arriving at the journey's end with passengers and train intact.

"Autocars."—The new journal, the *Autocar*, referring to the Chicago *Times Herald* having offered a prize of 5,000dol. for the most satisfactory vehicle in a performance over the 100 miles of road between Milwaukee and Chicago, says it will show to what an extent the movement is laying hold of the American public when they say that over 60 different firms have entered vehicles. One of the first entrants is a machine to carry a complete load of 4,250lb., and to do 50 miles by electricity without recharging. The accumulators weigh 1,600lb., and the carriage can do 16 miles an hour. Amongst the others will be an aluminium-bronze engine of 6 h.p., weighing with the carriage only 140lb. It is probable, therefore, the journal adds, that some very remarkable results may be the outcome of this race, although in point of mere speed possibilities the vehicles will be at a disadvantage compared with their Continental competitors, as the course is a rough and trying one, and not to be compared with "the sand-papered roads of France."

Safety Fuse Competition.—The Verband deutscher Elektrotechniker offers a little prize of 300 marks (£15) for the best form of unchangeable fusible cut-out, with the view of obviating the insertion of fuses for higher current strengths than may be determined upon. As standard figures for this purpose are given—for the current, 50, 100, 400, and 1,000 amperes, with average distance between the fuse screws 70, 80, 95, and 110 millimetres, and as diameter of the screws $\frac{1}{4}$in., $\frac{5}{16}$in., $\frac{1}{2}$in., and $\frac{3}{4}$in. respectively. The judges in the competition are to be the Committee for the Introduction of Uniform Contact Sizes and Screws, whose recommendations were accepted by the recent Munich meeting of the Verband. Competitions, furnished with a motto, and accompanied by a sealed envelope containing the name of the sender, are to be forwarded up to April 1, 1896, to the Geschäftsstelle des Verbandes deutscher Elektrotechniker, Berlin, Monbijouplatz 3. The announcement of the winner of the premium will be made at next year's meeting of the Verband in Berlin.

Tractive Power of an Electric Locomotive.—On October 6 electric locomotive No. 1 (which has often been referred to in our columns), used in hauling freight trains through the Belt Line tunnel of the Baltimore and Ohio Railroad, demonstrated that its drawing power far exceeded the expectations of its builders. Forty-four loaded freight cars, and three steam locomotives, not working, which had been used to haul the heavy train on the surface, were coupled to the electric giant at the tunnel entrance and pulled up the heavy grade of the tunnel, a speed of 12 miles an hour being developed. The total weight of the train was 1,900 tons. The drawbar pull exercised in starting this unusually heavy load was more than 60,000lb., and continued throughout the trip at more than 40,000lb. Baltimore and Ohio officials claim that no steam locomotive ever approached this record. No. 1 has been in regular service day and night since August, hauling freight trains through the tunnel, and has not missed a trip. Two smaller locomotives are building at the General Electric Works at Schenectady, N.Y., and upon their arrival in a few weeks the passenger service will be taken up and the tunnel operated entirely by electricity.

Electricity in Plant Growth.—Lieutenant Stuart-Smith suggests a reason for the great variation in the plant growth when there is but little apparent difference in the climatic conditions; he also offers a possible explanation of the action of light in producing chemical decomposition. In connection with the first part he states that bare wires placed in the ground, so that the current passing between them tends to pass through the roots of the plants, will greatly enlarge the roots of certain vegetables and the tops of others; and he suggests that earth currents, such as are known to exist, might have such an effect on the crops. A carefully-kept record may possibly show that over a large area during some years these earth currents may be much above the normal, while during other seasons they may be much below, and an examination of the crops might show heavy and light crops during those periods. Some correspondence has been found between crops and sun spots, and he suggests that earth currents may be the cause, as they certainly correspond with the activity of the sun. He then discusses at some length the effect of light on plants, and offers an explanation of the action of light in producing chemical decomposition on the basis of a true resonance effect.

Dr. von Stephan on Electrical Progress.—The resumption meeting of the Berlin Elektrotechnischer Verein on October 22 was marked by the presence in the chair of Dr. von Stephan, the postmaster-general, who expressed the hope that the members had come back from their summer holidays considerably reinvigorated, that the summer had acted as a good accumulator for storing their reserve force, and that contacts and batteries, leads and resistances and insulators would be found in good order. He alluded with satisfaction to the very excellent results achieved by German electrical engineers in the past year. Electricity had, he said, won for itself a very high place, both from a practical and scientific point of view. Through its many-sided applicability to nearly every branch of industry, every year witnessed an increase in the number of fields in which it was indispensable. Even in uncivilised lands electricity was forcing its way, and the savage now receives his bible with one hand and takes the electric light with the other. Dr. Stephan, in conclusion, made enthusiastic reference to the electrical installations carried out abroad by German firms. Subsequently, Dr. O. Fröhlich read a paper on "A Device for Compensating the Effect of Electric Railways," the demonstrations in connections with which were postponed.

Electric Alarm for Railway Carriages Wanted. A correspondent calls attention to the necessity of fitting all railway carriages with some simple and efficient system of electric alarm with which to call the attention of the guard or engine-driver of the train. The lighting of trains that pass through long tunnels in the daytime is also insisted upon by the writer, who relates the experiences of three lady friends who travelled on Wednesday by a Great

Digitized by Google

Northern train from Wakefield to Leeds. On the departure of the train, the ladies found themselves in the company of a man who was evidently insane. The train had left the platform before the discovery was made, and a run of about 20 minutes to Leeds without stopping was the sole alternative. His gestures and threats caused the lady passengers genuine alarm; but to add to their annoyance and risk a tunnel of some length intervened, and no light had been provided in the carriage. "It is idle," adds the writer, "for the railway authorities to call attention to their cord of communication with the guard, for all alike must recognise the utter futility of such means of alarm under circumstances of danger such as this; for the person who sits at the right-hand window can obtain full control over this communication, and the person in this case was the lunatic in question." Probably the Great Northern Company may soon find it advisable to equip more of their trains with the electric light, which is so easily switched on or off as the train enters or leaves a tunnel.

Electric Heating.—Mr. A. F. Nagle, writing in *Cassier's Magazine*, says no electrical appliances "are looked upon by the public with more favour than those designed for electric heating. They are simple and neat in construction; perfectly free from dust, smoke, or ashes; and are easily managed, requiring no skill or special training or fitness for the work; in fact, a child can manage them. Altogether the electric system is an ideal one of heating, except for one thing—its cost." Mr. Nagle goes on to consider the latter in comparison with steam for house-heating. He estimates that the loss in conveying current to the heater will be about 5 per cent. Taking 90 per cent. as the efficiency of the generator, and 10 per cent. to represent the mechanical friction of the engine, we get down to 77 per cent. for the efficiency of the mechanism from engine to heater. But the efficiency of the engine will probably not exceed 13 per cent. of the energy contained in the steam, so that the ultimate efficiency is 10 per cent., whereas if the steam were used directly for heating the efficiency would be between 90 and 75 per cent. Worked out on the basis of coal consumption, the result is no better—the ratio coming out 11 to 1 in favour of steam, instead of 10 to 1. In practice, however, as an ordinary house-heating system has to be compared with a first-class electric generating plant, the ratio is really 2 to 1 in favour of steam. The cost of attention, etc., is not, however, estimated in either case, the above figures applying only to the coal bill.

Etheric Lighting. — The fundamental principle employed in the Moore system of "etheric" lighting, as the inventor prefers to call it, consists in generating electric waves or vibrations suitable for producing luminous effects by interrupting the flow of electric current through a circuit of induction in a high vacuum as contradistinguished from a partial vacuum or one in which the rarefaction has not been carried beyond the point suitable for exhibiting luminous effects. The electric waves or vibrations so generated are made to produce luminous effects by action upon a receiver containing a rarefied gas. In order to produce etheric or phosphorescent light there is required a high E.M.F. with a short wave-length. Heretofore high E.M.F.'s have been obtained by the utilisation of counter E.M.F., due to the breaking of a circuit of high induction; but the degree of the counter E.M.F., or the final voltage obtained, as is well known, depends very largely on the suddenness with which the circuit is disrupted. In Mr. Moore's apparatus the circuit through the magnet is disrupted at a contact placed within a vacuum tube, the interposing dielectric being, instead of air, which is a comparatively good conductor, a vacuum of almost infinitely high resistance and inserted in the circuit in a minimum space of time. Another reason for the results obtained is that, as the vibrator is within a vacuum, it is free to move. That is, it has no air resistance, and practically it is proved that it vibrates at a rate of between 4,000 and 5,000 vibrations—that is, three or four times as fast as the same vibrator would vibrate in the open air.

The Training of the Young Engineer.—The inaugural meeting of the fifteenth session of the Institution of Junior Engineers was held on November 1 at the Westminster Palace Hotel. In the absence abroad of the retiring president, Mr. Alexander Siemens, the chair was taken by Prof. A. B. W. Kennedy, F.R.S., past-president. It was announced that Mr. Archibald Denny had been elected president, Lord Kelvin vice-president, and Mr. Hiram S. Maxim honorary member of the institution. The Chairman, in acknowledging a vote of thanks to Mr. Siemens and himself, said that he had the honour to be the first president of the institution. Since the year 1884 its membership had increased something like seven-fold, while its subscriptions had increased twenty-fold. The new president's address was devoted to an examination of the qualities and training necessary to a young engineer in order that he might be successful in his profession. He thought that all young men should start with a good English education, with Latin and Greek curtailed to the minimum possible amount. Mathematics, and the elements of mechanics, chemistry, and physics, should be thoroughly mastered, so that at the age of 16, or at the latest 17 provided the boy's physique was fairly developed, his apprenticeship might begin. The lad should spend the six summer months at the bench, and the six winter months at a first-class technical school or college. At the end of three years, or four years at the most, the youth should be quite ready for the drawing office; the shorter period should suffice in the shipbuilding yard, and the longer period for the marine engineer.

Copper Safety Fuses.—In the current number of the *Transactions* of the American Institute of Electrical Engineers are printed some remarks made by Mr. C. P. Steinmetz at the Niagara meeting of the institute, criticising the statement that copper fuses are superior to any other fuse. This statement Mr. Steinmetz believed to be based upon a misunderstanding of the object of the fuse. A fuse, he said, is not in circuit only to open the circuit at a dead short-circuit. It is not even the best means for this. A magnetic circuit-breaker, or any other circuit-breaker, is far superior to guard against short-circuits, because fuses will not always open on dead short-circuit with unlimited power behind. The object of a fuse is to open the circuit if the loads exceed the carrying capacity of the lines or the rated load. In this case, where the fuse is used in its proper place to guard against excessive load by cutting out the circuit at, say, 50 per cent. overload, the comparison between copper and lead fuses leads to quite different conclusions. Neither of these fuses will blow with such an explosion as on dead short-circuit. Both will be perfectly safe to open the circuit, but as soon as the load approaches fusing point the copper fuse will be red hot, due to the high melting point of the copper, and thus liable to ignite dust or other combustible material, and set the building on fire. Thus the lead fuse is preferred to the copper fuse, not because it behaves better under a dead short-circuit, but because it opens the circuit and blows a temperature below that which will ignite combustible material, and for this reason copper or any other metal with a high melting point is absolutely unsuitable for fuses,

Digitized by Google

except in particular instances where the conditions are such that it can ignite nothing.

The Propagation of the Magnetism of Iron.—Herr W. Peukert discusses this subject. When a long straight iron bar is excited by a magnetising coil situated at the centre, the lines of force, all of which pass through the coil, do not keep in the iron up to its extreme end, but emerge into the air at all points along its length, so that the induction in the bar falls off continuously as the distance from the central source of magnetisation is increased. With a periodically varying magnetising force the same effect is produced, and, moreover, the corresponding periodic changes in the induction induce eddy currents in the iron. These cause a lag in the phase of the induction, which increases as the end of the bar is approached. Experimental proof of this was carried out on rods of about one metre length of wrought and cast iron, and on a large bundle of soft iron wires of 1mm. diameter. The induction at various points was measured by search coils placed at intervals on the bar, and readings of the instantaneous values of the induction were taken through a complete period for each coil. The readings were obtained by means of a contact-maker fixed on the alternating-current dynamo used for exciting the magnetising coil, the momentary currents being indicated by a Wiedemann galvanometer. Magnetomotive forces of 288 and 1,306 ampere-turns were used. The curves of induced E.M.F. obtained from all three samples show a shift of phase which increases with the distance of the search coil from the centre of the bar, both at the lower and at the higher values of the induction. The curves are not symmetrical with the zero axis, the difference being attributed to residual magnetism. There is no marked difference between the changes of phase produced in the solid and in the laminated specimens, the amount of shift not being sufficiently clearly defined to show any distinct difference. The magnitude of the deflections continuously falls off along the bar, showing the diminution in the induction.

The Trend of Electrical Development.—In years gone by, remarks *Electricity* of New York, almost the entire energy of investigators into electrical science was devoted to the improvement of the primary battery. There was indeed reason for this in that its efficiency was comparable to that of the steam-engine and far in advance of any known methods of obtaining any available energy from fuel. Its drawbacks, however, were many. The fuel, which was zinc, and the atmosphere in which it was consumed, which was the acid or saline solution, were far more expensive than coal and atmospheric oxygen, and the care required to keep the batteries in working order was excessive and burdensome. It seemed very possible, however, to so improve the details of the battery as to render its care less irksome, and invention turned its attention with considerable success in that direction. How to produce a cheaper fuel and atmosphere, however, was not so apparent, and practically no progress was made in that direction. With the advent of dynamo electric machines producing electricity from ordinary coal and atmospheric oxygen through the intermediary of the boiler and steam-engine, notwithstanding an inefficiency of over 90 per cent. as against about 20, the primary battery came into disfavour, and those who continued the investigation of the great problem connected with it became themselves the subject of obloquy and derision. The dynamo electric machine, the journal considers, has now been developed so nearly to its theoretical limit as to leave no reasonable expectation of any further advances in the way of efficiency. In the meantime electro-chemical science has been advancing with giant strides, and many metallurgical operations which before were dependent directly upon the combustion of coal are now performed more quickly and more cheaply by the intervention of the boiler, engine, and dynamo. It is the dynamo itself that has rendered this possible, and the next step will be that the dynamo by familiarising us with electro-chemical processes will enable us to produce electricity itself by electro-chemical processes. There seems to be no question, in the opinion of our contemporary, that galvanism is to be re-enthroned in the near future. It will not entirely supplant dynamo electricity, however, for the latter will always have its field of usefulness, and there will always doubtless be conditions where, even with its 90 per cent. inefficiency, it will be cheaper than the battery method, but it is not to continue to hold undisputed sway as it has done during the past decade and more. It is idle, the writer imagines, to suppose that any method can be devised of consuming zinc to compete with coal. The economic possibilities of batteries consuming zinc have been almost as nearly reached as have those of the dynamo, and no further progress can reasonably be expected in this direction. Nor is it reasonable to expect that electricity will be generated by chemical means directly from coal. The fuel for our boilers requires some preparation before it can be economically employed there, and it is to be anticipated that it will require some special preparation to adapt it to the direct production of electricity. Under our boilers the admission of atmospheric oxygen has to be carefully regulated, else the results obtained are unsatisfactory. It is not unreasonable, then, to expect that the method of burning our fuel for direct electrical production will have to be carefully considered. The direct production of electricity from fuel does not therefore mean the burning of an unprepared fuel in an uncontrolled atmosphere, but means a proper preparation of both, and their especial adaptation, so that the latent energy may become manifest in the electrical instead of the heat form. These, the journal concludes, are all problems for the electro-chemist, and they are problems that are being attacked by so many vigorous thinkers that their solution must be in the order of things.

Brazilian Telegraphs.—The official report of the Brazilian Minister of Telegraphs to his Government in reply to the memorandum which Sir John Pender submitted to it has been published. The memorandum, it may be remembered, contained the bases of an agreement which Sir John Pender desired to conclude with the Government for the working of the submarine cables now belonging to the Western and Brazilian Telegraph Company in conjunction with those of the Brazilian Submarine Cable Company, of which he is the chairman. The Brazilian Government has virtually concluded arrangements for the purchase of the Western and Brazilian lines, which are laid along the coast of Brazil, and give communication with the other republics in South America, and Sir John Pender, in his memorandum, intimated that unless his proposals were accepted the benefits of that purchase would be to a great extent lost by the laying of a competing cable direct to the River Plate, thereby avoiding the present route over the Government's proposed acquisition. The Minister deals at length with the facts alleged in the memorandum in connection with the past history of both undertakings; in effect it is claimed that full consideration has been shown in the past to the Brazilian Submarine Telegraph Company, while the conduct of the managers of that undertaking, together with the attitude now taken by Sir John Pender, warrants the suspicion with which his actions are obviously regarded in Brazilian Government circles. It is clear that if Sir John Pender's object be to prevent

Digitized by Google

the purchase of the coast cables, he has adopted the very course most calculated to drive the Government into a speedy completion of their arrangements. The veiled threats in the memorandum, and the tone of the speeches since delivered in London, are not of a character that a responsible Government can submit to from a private individual, even of the high standing of the head of the telegraph "ring." One other point in the dispute of a personal character may be mentioned. The Minister of Telegraphs writes in his report: "With respect to the complaint that Despecher, Sir John Pender's agent, had not received the consideration which was to have been expected, I have to state that the latter was always received with the greatest courtesy by this Department under the orders of your predecessor, and if his mission was negative in its results, this was due to his not conforming with the original requirements of the concession." In commenting upon this report the *Daily News* says: "The question of the respective benefits to the public and to the proprietors of the defeat or establishment of a cable monopoly is, however, a matter of less immediate concern in this connection than the international complications which have arisen through the taking possession and present retention of the island of Trinidad by the British Government, ostensibly in connection with the cable schemes of Sir John Pender. A perusal of the document now under discussion shows that the Brazilian Government obviously has special reasons for attaching importance to the island, the possession of which is regarded as the key to the telegraphic situation. If this isolated barren rock be Brazilian territory, it cannot be utilised for cable communication in opposition to the existing systems, the Government having two years ago given a guarantee against such competition. The possession by a foreign Power would facilitate the rival schemes with which Sir John Pender threatens the authorities at Rio, with the alternative of confirming his own monopoly. British capital and the good relations which have hitherto subsisted between this country and Brazil are seriously imperilled for no better cause than a not too creditable telegraphic intrigue. A careful consideration of the circumstances, as embodied in the document to which we have alluded, may assist the Government to withdraw from what would appear to be a false position. It was doubtless assumed under a misapprehension of some of the facts involved." An interesting sidelight is thrown on this affair by the correspondence between the Western and Brazilian and Brazilian Submarine Companies which appears in another column.

Protection from Lightning.—A circular of information bearing this title, by Mr. McAdie, of the United States Weather Bureau, is published as Bulletin No. 15 of the United States Department of Agriculture. The pamphlet is rich in statistics, and contains numerous practical deductions; it has illustrations of lightning conductors, of objects struck by lightning, and some photographs typical of lightning discharges. Among the more important and interesting statistics and deductions are the following: During the five years, 1890 to 1894, an average of 224 lives a year were lost in the United States due to violent wind storms, tornadoes, and lightning; during the nine years ending in 1893 there were in the United States 4,175 fires caused by lightning, representing a total loss of over 14,000,000dol.; during the 10 years ending in 1893, 2,679 barns, 129 churches, and 831 dwellings were struck by lightning; their geographical distribution is given; the loss of life and property in 1894 is discussed in detail; the region of the greatest number of thunderstorms is in the south-eastern part of the United States; an interesting result of the statistics is that there is a decreased liability to accident in thickly-settled communities, the risk in the country being five times as great as in the city; lightning rods are hardly necessary for dwelling-houses in city blocks, a considerable protection being afforded by the tin roofing, cornices, etc. If 1 represents the frequency of lightning strokes in a chalk formation, 2 will represent it for marl, 7 for clay, 9 for sand, and 22 for loam; the oak is the tree most frequently and the beech the one least frequently struck; the statistics show that the trees which are struck are not necessarily the most prominent, but rather those which are near ditches full of running water or near temporary watercourses. A theory of lightning conductors is discussed: the function of the lightning rod is twofold, that of conducting the charge to earth and that of preventing a disruptive discharge by silent neutralisation of the cloud electrification. Lord Kelvin, at the British Association meeting of 1888, stated that there is "very strong reason to feel that there is a very comfortable degree of security, if not of absolute safety, given to us by lightning conductors, made according to the present and orthodox rules." A set of rules for the erection and maintenance of rods is given: one should use a good iron or copper conductor, and if the latter, one weighing about six ounces to the foot, preferably in the form of tape; iron appears to be as efficient as copper, and it should weigh about 35oz. to the foot; a sheet of metal is better than a rod of the same cross-section; the nature of the locality will determine the need of a rod; the very best ground obtainable is a very poor one, and one can therefore not overdo the matter in the making of a good ground; the earth-plates should be buried in damp earth or running water; when the conductor is near water or gas mains it should be connected with them; the neighbourhood of small fusible gas-pipes and indoor gas-pipes should be avoided; the top of the rod should be protected from corrosion and rust; independent grounds are preferable to water and gas mains; clusters of points are recommended; chain or link conductors are of little use; very little faith is placed in so-called area protection; some uncertainty exists in regard to the return shock, which is caused by the inductive action of charged cloud on distant objects; regarding the indifference of lightning to the path of least resistance, Lodge says "it is simply hopeless to pretend to be able to make the lightning conductors so much the easier path that all others are out of question"; the path will depend largely on the character of the flash; while parts of a building protected by a rod may be struck, the majority of flashes in our latitude are not so intense but that a well-earthed lightning rod makes the most natural path; there are many instances, however, where buildings were struck below the rods; buildings may be damaged without having been struck at all, as by an induced spark near escaping gas; there is no good reason why a place once struck may not be struck again. It sometimes makes but little difference whether trees are higher than the adjoining buildings or not—the lightning may strike them indiscriminately; it is not judicious to stand under trees, in the doorways of barns, close to cattle, or near chimneys and fireplaces, but there is no reason to try to insulate oneself; small steel objects do not attract lightning; if a person is struck people should at once try to restore consciousness, as lightning often brings about suspended animation rather than death; instructions for resuscitation are reprinted. No better illustration of the value of lightning conductors can be had than the one on the Washington monument. It appears that a barn is more liable to be struck when filled with crops than when empty.

THE WESTINGHOUSE UNDERGROUND SYSTEM FOR ELECTRIC TRACTION.

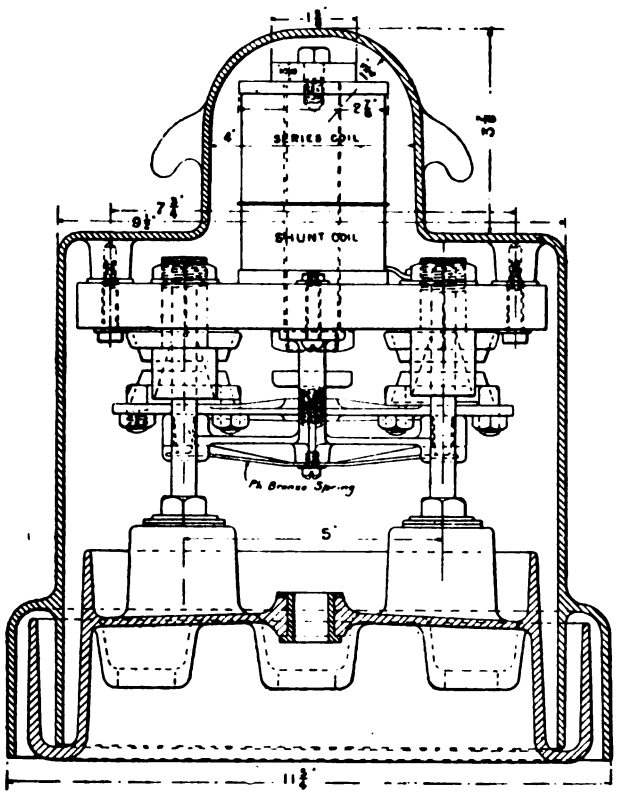
(Concluded from page 505.)

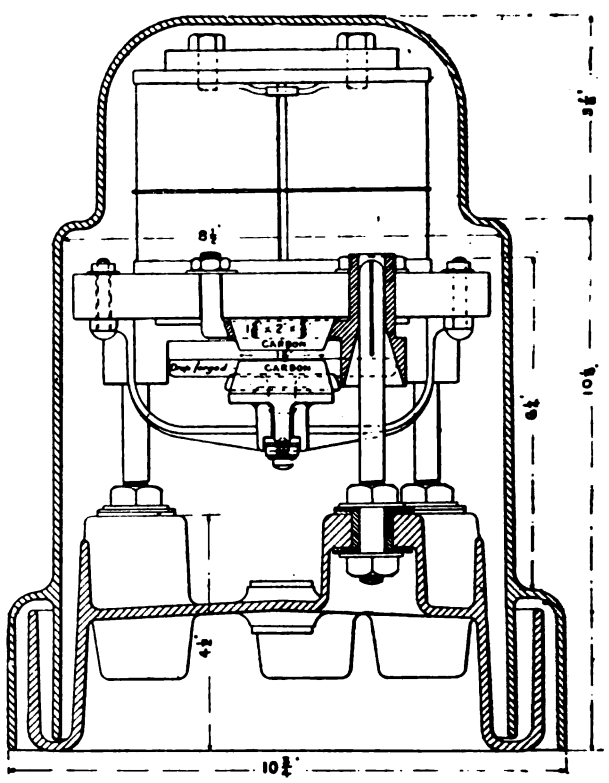
As promised in our list issue, we are now able to give an illustration of the automatic switching gear designed for the system described there. The apparatus has many points in its construction which are novel. The details of the switch, etc., can be seen in Figs. 4, 5, and 6, which represent a plan of the apparatus and two sectional elevations.

The electromagnet used has two coils—one of fine wire, which receives the current from the small battery carried by the car; the other of larger wire, which takes the current passing from the main to supply the motor on the car when contact is made. The action of this second coil is simply to reinforce that of the first coil, and to strengthen the pull of the electromagnet in order to secure a firmer contact. On this electromagnet being excited by the battery in the car its armature is attracted, thereby bringing into contact two sets of double carbon blocks. The carbon blocks mounted on the moving armature are connected together, while those fixed to the upper part of the mechanism are insulated from the frame. One of these carbons is connected to one of the points in the road through the thick wire of the series coil, and the other is connected to the main. It will thus be seen that when the four carbon blocks go together, the connection is made between the main wire and the third contact point. Carbon contacts are used, because they will not stick together by the action of the current, nor arc destructively when breaking the current accidentally. This switch is mounted in a cast-iron case similar to a diving-bell. The base on which this diving-bell fits has a circular groove, which is filled with oil.

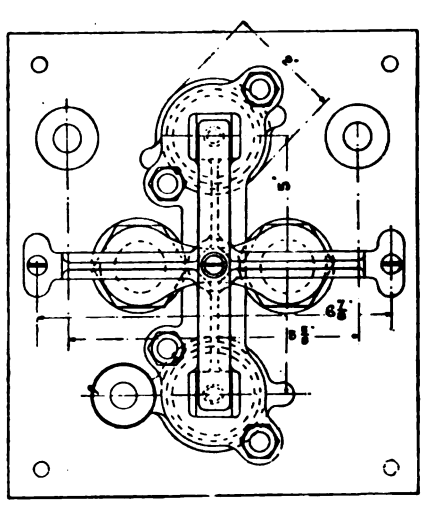
The mouth of the bell itself contains a somewhat smaller groove, so that when the two are placed together an S-shaped channel is formed, and a complete oil seal is obtained, which prevents the entrance of dirt or moisture. The base has knobs on it carrying insulated pins, which are permanently connected to the various wires on the surface of the road and the main wires. The pins have their heads split, and fit into holes the openings of which are tapered, so that the mere effect of placing the bell into position on its base will make all the contacts necessary for the switch; and in the event of the switch going wrong the bell can easily be lifted off and a new one placed in its position, such an operation occupying but the space of a few seconds.

The diving-bell construction and oil seal make an absolutely water-tight case for the switch, which will remain dry even if the whole surface of the road is covered with water. These bell switches are generally placed two in a manhole in a 6ft. way, one controlling the up line, and the other the down line. It can therefore be readily seen that the chances of leakage and accident to the wires are very much reduced, as by the construction of the switch shown, the insulation of the mains can be practically made as high as may be desired, and everything being buried underground no accidental damage can be done to the wires. Fig. 7 shows two sections through the contact points on the track. The contacts are of wrought iron set in earthenware blocks.





FIGS. 4, 5, AND 6.—Details of the Westinghouse Automatic Switch.



A SUCCESSFUL AND SIMPLE METHOD FOR PREVENTING ELECTROLYTIC DECOMPOSITION BY RAILWAY CURRENTS.*

BY MR. FOREE BAIN.

A great deal has recently been said in regard to the deleterious effects of railway circuits in their action on water-

* From the *Electrical World* (New York).

Digitized by Google

pipes, etc., and several more or less complicated remedies have been suggested, some of such embracing special dynamos connected in various novel if not effective ways to special and additional circuits. All of such might meet with careful consideration if the evil could not be entirely cured and prevented by the simplest and most rational method, which is free for use without royalty, and which may be used by any one afflicted with the trouble to which this article refers. The remedy, in a nutshell, consists in having underground conducters equal or greater in current-carrying capacity than that of the overhead conductors, not considering the rails as a part of the circuit. The integrity of the underground circuit must be as carefully preserved as that of the overhead conductors. A failure in this may not lead to immediate disaster, as with the overhead conductors, but it will result in disaster postponed.

Local disintegration of uninsulated conductors laid in the ground is continually going on. The damp earth forms the electrolyte through which parasitic currents will flow between the copper conductors and other metallic bodies adjacent thereto, which are either electro-positive or electro-negative to the copper. This action is galvanic, and continues quite independent of the dynamo current flowing in the conductors, and constantly tends to change the carrying capacity of the underground conductors; added to this is the oxidising of the contacts, and the corroding action of other joints and contacts, all tending to increase the resistance of the circuit. Therefore, it may be seen that the carrying capacity of the underground leg of the circuit is constantly becoming smaller, so that it becomes necessary to start with it abundantly large, and to protect it against these effects as intelligently and as persistently as we maintain the insulation of the overhead conductors.

Local galvanic action, such as I here describe, is not that which damages the water-pipes or which makes enemies of our telephone friends, for it is only a small thief, the servant of time and the anti-fat of our underground circuits, reducing the carrying capacity of our meagre, niggardly provided underground conductors to such a degree that the current must stray away to water-pipes, gas-pipes, telephone lines, and other conductors which happen to be approximately in the path, and at many and divers points, leave such to again return to the rails or to other systems of pipes. In its ramifications it performs work by electrolytic decomposition at every point in the circuit where a marked difference of potential exists, and where the current passes from the underground piping where in contact with an electrolyte, such as damp earth.

Now, supposing an ideal construction in which the rails were electrically continuous, and of amply large carrying capacity and low resistance, so that there would be but a slight difference of potential between the extreme ends where the current enters and where it leaves them; when the maximum current is flowing, the path of the lowest resistance being through the rails themselves, then there would be no appreciable electrolytic decomposition of the water and gas pipes in the neighbourhood of such a road, for the reason that the legitimate circuit provides a much lower resistance than the extraneous conductors. The rails as electric conductors cannot, however, be depended upon in practice, and should not be considered as a part of the circuit for an electric railway system. There should be a sufficiently ample conductor in the return circuit, in addition to the rails, such conductor at least equaling the joint capacity of the trolley wires, the mains and feeders of the overhead leg of the circuit, in order to secure desirable results and maximum economy.

I have equipped in this manner several notable, important, and successful roads, which have been in successful operation for about five years, and which have been entirely free from causing electrolytic decomposition of water and gas pipes and any objectionable telephone disturbances. The rails were bonded in the usual manner, and a No. 0 copper wire was laid between the rails and connected by cross wires to each bond wire. A large stranded, uninsulated copper wire, in some instances as large as 1,000,000 circular mils, was laid just outside of one of the rails in a trench and connected to the central No. 0 copper conductor at intervals of every 100ft. or more, according to the traffic on that portion of the road. This large stranded conductor was thoroughly insulated in the following manner: A continuous trough made of 2in. pine lumber, previously boiled in fernolene, was constructed. This was made about ½in. larger all around than the conductor or conductors it was to contain; the trough was laid in a trench outside of and parallel with the rails, and deep enough to be below the street paving. The conductor was laid in the box, and the taps leading out were attached at desirable intervals. The conductor was supported from the bottom on small cross sticks of prepared wood at intervals of 5in. or 6in. The box or trough was then filled up with hot pitch, the top nailed on, and the trough covered over. The taps connected to the central conductor were thoroughly insulated. It is more convenient to lay the underground circuit whip-stock fashion than to follow the feeder plan. The ground terminal of the power plant was connected to this conductor, and not to the rails as usual. In one instance I noticed that the telephone service was greatly disturbed at one time when I connected the ground terminal at the power-house to the water-pipes for the purpose of testing the efficacy of the arrangement, and I also noticed that the disturbance disappeared at once as soon as the water-pipe connection was removed.

The value of a plan such as I have outlined is determined by its successful and continuous operation for a reasonable period of time, and I can therefore safely say that the

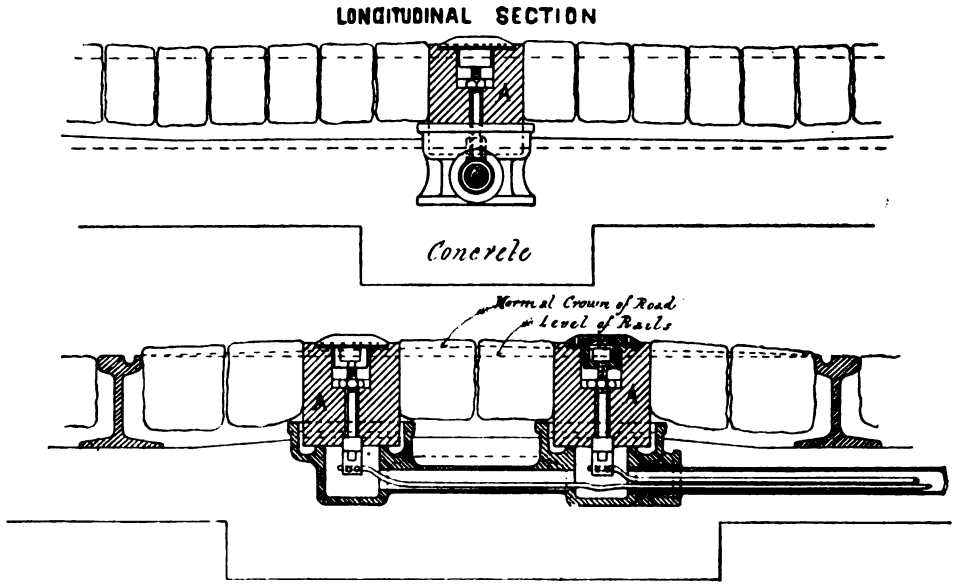


FIG. 7.—Sections through the Road Contacts.

Digitized by Google

suggestions which I have offered have had a sufficient test in practical operation to render the plan valuable and reliable. The auxiliary track conductor may be placed on poles if desirable. In this case it may or may not be covered with insulation; being approximately at the same potential as the earth there is no danger, and the leakage will be negligible, and being removed from the ground the galvanic action is also nil.

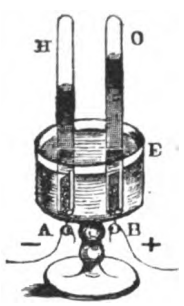
LECTURE XV.—SIMPLE PRINCIPLES AND USE OF ELECTRIC MEASURING INSTRUMENTS—AMPERE-METERS, VOLTMETERS, DELICATE MIRROR GALVANOMETERS, RESISTANCE COILS.

(Specially Contributed.)

(Continued from page 508.)

Voltameter.—The apparatus used to decompose these compound liquids is called a voltameter, and consists in one form of a vessel, E, containing, say, acidulated water, in which are two strips of platinum—each strip of platinum is connected, as shown, to its respective battery terminal, A B.



In this case, when the connections are duly made with the battery, bubbles of gas will be given off from each platinum plate. In order to store and to enable an examination of these gases to be made, test tubes or similar tubes are first filled with the acidulated water, and carefully inverted over the platinum strips. Then, when the battery connections are made, the gases from the platinum strips collect in the tubes, H O, forcing out the liquid as they collect. In the case of acidulated water, one tube fills with gas at double the rate of the other. The reason of this is that water consists of two elements—hydrogen and oxygen. These two elements in the elemental state are gases, and so when the water is decomposed are given off and collected as gases. The combination water consists of *two* parts of hydrogen by volume and *one* part of oxygen by volume, so that the platinum strip giving off hydrogen gives off twice the volume of that gas as the other strip does oxygen. Chemists symbolise the composition of water as H_2O, meaning that two parts by volume of hydrogen combine with one part by volume of oxygen to form the combination known as water. It is not my intention, however, to enter into the chemistry of electrolysis, though, I may say, I believe it to be one of the most fascinating, one of the most important, and one of the least investigated phases of electrical work. *The* important point to which I wish to direct your attention, is that *similar quantities* of electric current always give rise to the same amount of chemical decomposition. Thus 10 amperes of current for one minute will decompose exactly the same amount of acidulated water as one ampere of current for 10 minutes. This brings me to another unit of importance, especially in electrolytic work,

The **ampere per second**, which is named the **coulomb**.

If C = amperes, and t = time in seconds,

then $C\,t$ = coulombs.

Terms used in Electric Decomposition:

Electrolysis—Chemical decomposition by the aid of an electric current.

Electrolytes—The chemical compounds capable of being electrically decomposed.

Electrodes—The ends of the conductors from the battery or other source to the electrolyte.

Anode—The electrode by which the current enters.

Kathode—The electrode by which the current leaves.

Ions—The products of electric decomposition.

Anions—The products of decomposition at the anode, sometimes called the negative ion.

Kations—The products of decomposition at the kathode, sometimes called the positive ion.

In the decomposition of water, hydrogen is found given off at the kathode, hence is called a kation. Similarly, when metallic solutions are decomposed the metals are deposited on the kathode, hence the metals are kations; while oxygen, chlorine, etc., are given off at the anode, hence are anions.

Quantitative Laws of Electrolysis—The current flowing through any section of a circuit is the same as that flowing through any other section, hence:

i. The amount of chemical action is the same at all points of the circuit.

ii. The amount of an ion liberated at an electrode in a given time is proportional to the quantity of the current—*i.e.*, as above stated—to the coulomb ($C\,t$).

iii. The weight of an ion liberated at an electrode in a given time is equal to the quantity of the current multiplied by the electro-chemical equivalent of the ion.

We have already seen (Lecture III.) that an ampere per second, or a coulomb, deposits from a solution of silver nitrate 0·001118 gramme during that time. Thus 0·001118 is the electro-chemical equivalent for silver. Similarly, 0 000010384 is the electro-chemical equivalent for hydrogen. Knowing one of these—say, that of hydrogen—other electro-chemical equivalents can be calculated.

To Calculate Electro-Chemical Equivalents.—

1. Experimentally determine that of hydrogen—that is, determine the weight of hydrogen liberated per coulomb. This is 0·000010384 gramme.
2. To obtain the electro-chemical equivalent of another element, multiply the electro-chemical equivalent of hydrogen by the *chemical* equivalent of the other element. Thus, the *chemical* equivalent of silver is 107·67, hence the electro-chemical equivalent of silver is

$$0{\cdot}000010384 \times 107\,67 = {\cdot}0011804528.$$

Electrolytic Action as a Practical Measurer.—From what has been said it ought to be seen how electrolysis can be used to measure coulombs—that is, ampere-seconds—for

$$\text{Coulombs} = \frac{\text{weight of metal deposited in grammes}}{\text{electro-chemical equivalent of the metal}}$$

Thus, if silver is deposited, then

$$\text{Coulombs} = \frac{\text{weight of silver deposited in grammes}}{0{\cdot}00118}$$

If copper is deposited, then

$$\text{Coulombs} = \frac{\text{weight of copper deposited in grammes}}{0\,000328.}$$

However, for practical purposes—that is, for electric lighting or power work—the electrolytic method of measurement is not widely adopted. Too many errors are likely to creep in connected with time, weight, temperatures, checks, and inspection, although Mr. Edison has introduced and brought to considerable perfection a measuring instrument of this kind.

Electrical engineers use energy during intervals of time, or, they use power.

The Board of Trade unit is the kilowatt-hour—that is, 1,000 watts per hour.

A watt-hour is 3,600 volt-coulombs; for a coulomb is an ampere per second.

A kilowatt-hour will therefore

= 1,000 × 3,600 volt-coulombs.

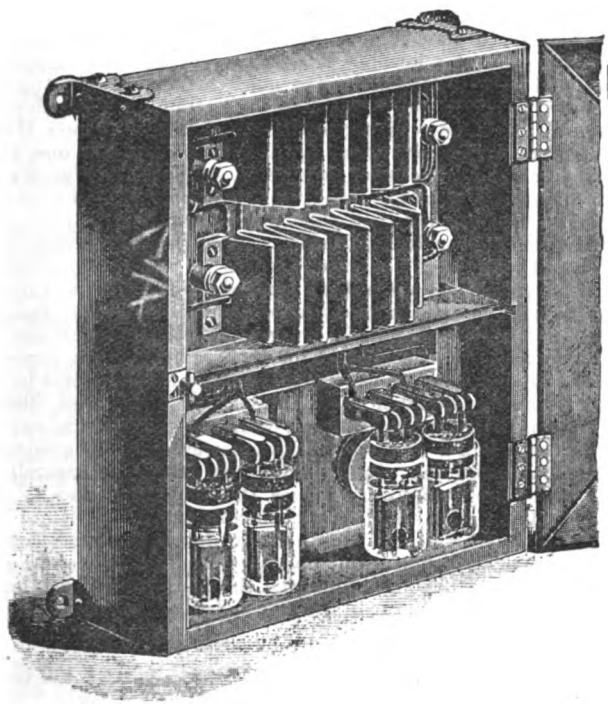
= 3,600,000 volt-coulombs.

So that if in distributing electric energy we maintain the volts constant, knowing the voltage and determining the

Digitized by Google

coulombs, we can find the Board of Trade units; and if the charge per Board of Trade unit is, say, 6d., the user's bill is easily made out. Unfortunately for this kind of measuring instrument, the voltage is rarely, or never, constant over any length of time.

Edison's Electrolytical Meter.—A recent form is herewith illustrated. On the lower shelf are four voltameters



with plates of pure zinc alloyed with 2 per cent. of mercury in a solution of pure zinc sulphate. The voltameters are shunts on the circuit so arranged in order to use only a small fraction of the total current, the main current going through the zigzag German-silver resistance on the upper shelf. In order to get rid of the disadvantages arising from variations in temperature, a copper coil resistance is put in the shunt circuit. The variation of resistance of the German silver is little with the variation of temperature, and that of the copper coil increases or decreases as that of the zinc sulphate solution decreases or increases, so compensating the resistances and keeping the total resistance on the whole fairly constant. The kathode plates are carefully weighed each month to know the number of coulombs, or of Board of Trade units, to be charged to the customer.

$$\text{Coulombs} = \frac{\text{weight of zinc deposited in grammes}}{0{\cdot}000337}.$$

ELECTRO-CHEMICAL EQUIVALENTS.

Hydrogen	0·0000104
Gold	0 0006791
Silver	0 0011181
Copper (cupric)	0 0003281
Zinc	0 0003369
Lead	0 0010716

A formula may be given for the weight of metal deposited in time, t, by a constant current, C.

Let E.C.Q. = electro-chemical equivalent,

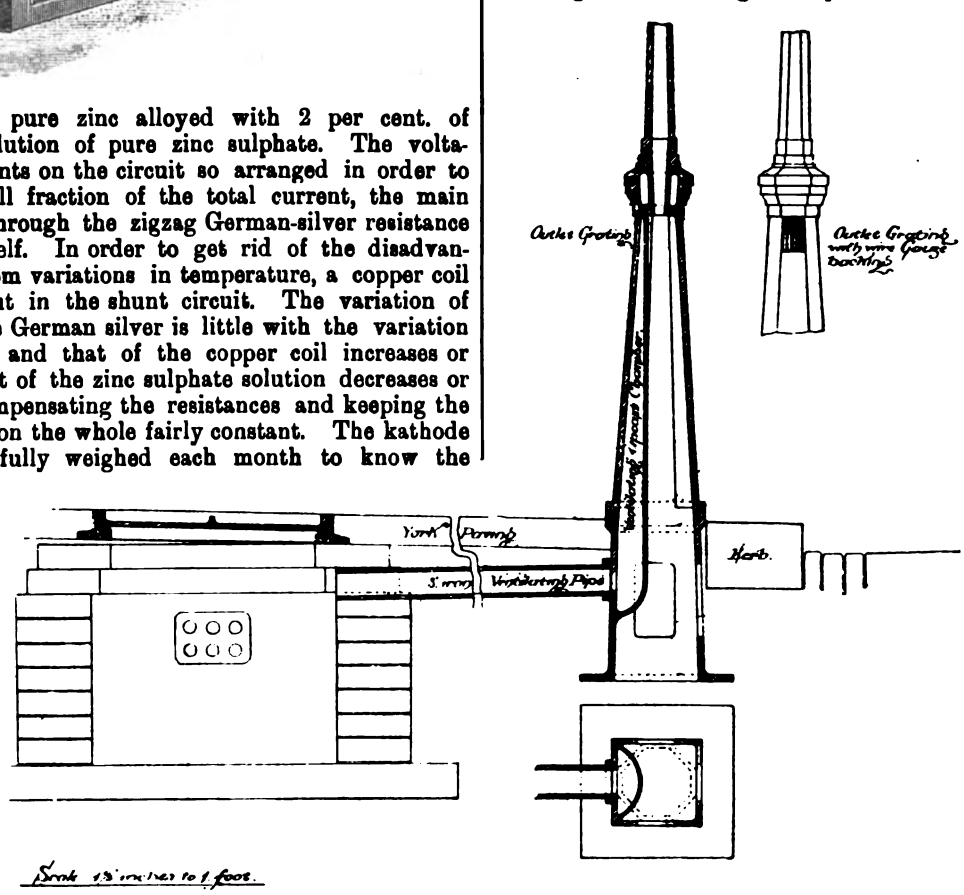
then

E.C.Q. (of metal, m) $\times$ Ct = w (weight in grammes).

WEAVER'S VENTILATING LAMP-POST.

The explosions which have taken place from various causes in electric light distributing boxes have called attention to means for preventing such explosions. One of the simplest, best, and least expensive which has come before our notice is that designed by Mr. W. Weaver, C.E., chief surveyor of Kensington. The designer has utilised his extensive knowledge of what may be termed street work in towns, and, instead of interfering in any shape or form with the curbed path or street, prefers ventilation through a specially designed lamp-post. This obviates increase of obstruction and interference with the public highways necessitated by the fixing of special dwarf ventilating posts, perforated gratings, and other suggested methods.

Mr. Weaver's post, as will be seen from the illustration, is extremely simple, and differs only from ordinary lamp columns by having an inner chamber cast in the lower half of the column, with a ventilating outlet grating at the top of the chamber, and a collar at the bottom for receiving a pipe laid from the box or culvert to be ventilated. The outlet gratings, which can be made of various sizes, are protected with gauze to prevent back-firing. The posts are being used extensively in Kensington, the Vestry allowing the electric light companies £1 for each ordinary lamp-post (worth £1. 15s.) removed and delivered to them, and fixing and making good round the special posts free of charge. The agents for the post (which is provisionally protected) are the Safety Tread Syndicate.



Weaver's Ventilating Lamp-post.

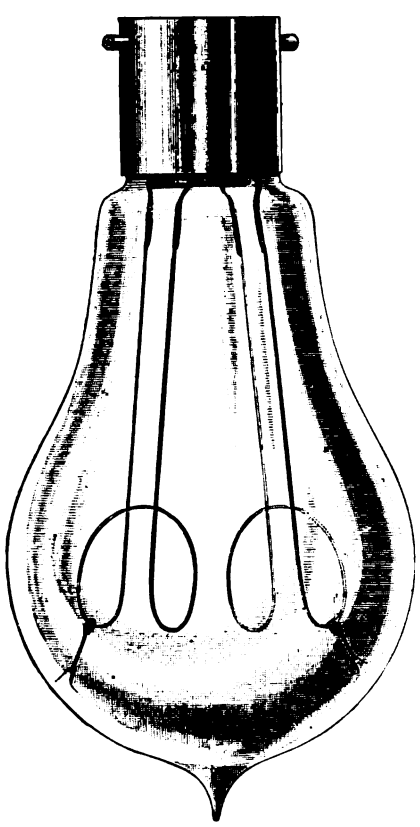
HIGH-VOLTAGE LAMPS.

We have received from Messrs. G. Straus and Co., Limited, of 130, Queen Victoria-street, London, E.C., and Schwechat, Vienna, their catalogue of incandescent lamps and accessories. We note that in the lamps listed the

Digitized by Google

candle-powers range from ¼ to 1,800, the voltage from 1 to 280, the watts from 1½ to 3½ watts per candle-power. Especially classified are the following lamps: "Long Life," or 3½-watt lamps; "High Efficiency," 2½-watt lamps; ditto, 1½-watt lamps; low candle-power, or battery lamps, for small accumulators, for decorative, dental, surgical, and microscopic purposes; high candle-power lamps; high-voltage lamps, of 8 c.p. and upwards; fancy tubular, olive, crinkled, grooved, festooned, filigree, conical spirola, candle flame and flat lamps, switch lamps and focus lamps; and illustrations are given of 34 various sockets which this firm supply.

We illustrate herewith a specimen of the Straus high-voltage lamp. The firm claim that, with their special carbons, even lamps of from 8 c.p. to 10 c.p. can be supplied with the same efficiency and durability as at the usual voltage of 100, and they reproduce in this catalogue a *fac simile* of a letter from Mr. S. W. Baynes, dated Bradford electrical engineer's office, July 4, 1895, in which he says: "I put on test about 12 or 14 of the 230-volt 16-c.p. lamps you originally supplied. They were burnt continuously for over 3,000 hours without a single breakage. The average watts per candle-power was about 3·2 and 3·1



during the early stages of the test. On examining the bulb after so long a test you could scarcely tell that the lamps had been in use, there being little or no deposit of carbon on the glass."

The establishment at Schwechat, near Vienna, where these lamps are manufactured, consists of the arc-lamp carbon works of Messrs. Schiff, Jordan, and Co., and the printing and colour lithographic works of Messrs. Schiff, Srpek, and Co., with common offices, etc. Soot is used in both trades, and the soot furnaces form an important part of the works plant. The joint establishment comprises some 30 buildings, covering an area of about 20,000 square metres, and includes houses for the officials and artisans employed. In the testing building, 60 arc lamps, of both Austrian and foreign manufacture and of various systems, are used for testing each brand of carbon. The machinery is for the greater part of English origin. For supplying power there are two boilers and a 360-h.p. compound steam-engine. The transmission of power from one works to another and the lighting of the whole establishment is electrical. Electric accident alarms and electric ventilators are also provided. In addition to the employés' houses, there are dining-rooms, baths for males and females, and an ambulance and first-aid room. The annual capacity of the carbon works is nearly 20,000,000 lineal feet.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D SC., F.R.S.

LECTURE I.

Physics of the Arc.

It is narrated of Faraday that he had a particular dislike for what he called "doubtful knowledge"; and it was one of his great achievements in electrical researches to clear up a number of things that came under that category. Some small fact had been discovered, it was obscure, it was not correlated to anything else. So long as it was not correlated to anything else, and not explained, it was unsatisfactory. And though science has gone on since Faraday's time, has developed, extended itself, become correlated all round, while now there are a hundred workers where formerly there was but one, still there are some branches of science in which knowledge is still in a very doubtful state. Into the category of doubtful knowledge I venture to put that phenomenon which was discovered by Humphry Davy during the last year of the old century, and received the name of "the arc."

Although arc lamps are to be counted by the million, though the arc light is used publicly in every town and city, though electrical engineers handle it every day, yet it still remains to be true that on the subject of the arc itself as a physical phenomenon, those of us who know most feel ourselves to be very ignorant. So much is still obscure and unknown, that—in spite of the researches of many workers—the physical nature of the arc is still a mystery. Many, however, of the complications that beset the enquiry have been gradually unravelled, and every fresh discovery brings the workers nearer to the explanation of that which is still unexplained.

To the physics of the arc, then, we devote this first lecture of the present course; the optics of the arc will claim our attention in the second; while the third lecture will deal with the recent developments in the mechanism of arc lamps.

Early Discoveries.

To introduce the subject of the physics of the arc I will begin at the beginning and briefly recapitulate the things which were discovered in the first instance. It is sometimes said—and you will find it repeated in text-books—that the discovery of the arc dates from about 1809. I venture, however, to put the date earlier. It was in June, 1800, that Volta wrote an account of his then newly-discovered pile to Sir Joseph Banks, the then president of the Royal Society. The pile having in that way been made public, a few workers in science immediately precipitated themselves upon that invention, and tried to find out all that could be found about voltaic piles. Amongst those who thus set to work to build voltaic piles for themselves was Humphry Davy, then apprentice with Dr. Beddoes, of Bristol. In September, 1800, Davy recounts how he was able to produce sparks that were visible in daylight from the discharge of his primitive pile; and he found in trying sparks between terminals of different materials that those sparks were of different degrees of brightness. Amongst other materials that he names, he mentions that the bright spark visible in daylight was obtained by using well-burnt charcoal. He found that to render charcoal well conducting it must be hard, dense, well burned, so as to be metallic in lustre, and, best of all, if it were suddenly quenched in quicksilver. This early experiment of Davy's is recounted in the October number of *Nicholson's Journal*, to which it was communicated in September. Within one year several other accounts are to be found. In the *Philosophical Magazine*, in the February number for 1801, Mr. Moyes, of Edinburgh, narrates how he had produced sparks in broad daylight from a pile with some 60 or 70 elements. Then we find Davy again (having in the meantime removed to London and become lecturer at the Royal Institution) describing, in the very first volume of the *Journal* of the Royal Institution, how he also had obtained sparks of vivid brightness, using still pieces of well-burned charcoal. He describes an apparatus for taking the spark in fluids, and he continued to show this in his lectures on electricity. In that same year—1801 or 1802—Tyndall records that "Davy showed the carbon light with a battery of 150 pairs of plates in the theatre of the Royal Institution." Some six or seven years ago I was hunting up in the British Museum, for an entirely different matter, some of the early numbers of the *Journal de Paris*, and in the course of that search I came across something I had not at all expected. Under the date 22 Ventôse, An X. (March 12, 1802), I found the following entry: "Le citoyen Robertson, auteur de la fantasmagorie, fait dans ce moment, des expériences intéressantes, et qui doivent sans doute avancer nos connoissances sur la *galvanisme*. Il viente de monter des piles métallique, au nombre de 2,500 plaques de zinc, et outant en cuivre rosette. Nous parlerons incessament de ces résultants, aussi que d'une experience nouvelle qu'il a faite hier avec deux charbons ardens. Le premier étant placé à la base d'une colonne de 120 élémens de zinc et argent, et le second communiquant avec le sommet de

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

la pile ; ils ont donné, au moment de leur réunion, un étincelle brilliante, d'une extrême blancheur, qui a été aperçue par toute la société. Le citoyen Robertson répétera cette expérience le 25."

This same Robertson was a Frenchman of Scotch extraction, whose name comes into the outskirts of science in two or three ways. He was the man who introduced the phantasmagoria, and visited London with it at a later date. It is also said that in the same year, 1802, two other persons showed the carbon light, a German of the name of Curtet, and Ritta, of Jena, the famous experimenter upon the polarisation of copper plates ; but the references are so scanty that one cannot verify the fact. But it is quite certain that in those two or three years of the century it became perfectly well known that a light could be produced in that fashion between two pieces of charcoal.

I may here take two pieces of charcoal well metallised, and connecting them to the wires from a powerful source of current I will perform Davy's fundamental experiment by putting them together, and then separating them to a distance of about $\frac{1}{10}$in. apart from one another, when at once we get this little flame of dazzling brightness between the two. The flame in this case is really very bright, both the tips of the carbons themselves shine brilliantly, and the flame itself, when using soft carbon of this kind, is very bright indeed. Holding the pencils horizontally, as Davy did, the flame is seen to take an arched form, as the result of the ascending air current. This circumstance originated the name arc, which we retain, though nowadays we hold the pencils vertically one above the other, and have no arch.

If anyone doubts still that the arc light was a known thing before before 1808, let him look at this book, John Cuthbertson's "Practical Electricity and Galvanism," published in 1807, wherein, on p. 260, there appears the following : "*Experiment* 209 : *Deflagration of Charcoal by Galvanic Action.*—The charcoal for this experiment must be made of some very close-grained wood, such as boxwood or lignum vitæ, well charred, cut into pieces about an inch long, one end being scraped to a point, and the other so that it can be held by a port-crayon fixed to the end of one of the directors ; then approaching the point of charcoal to the end of the other director, light will either appear or the charcoal will be set on fire. The particular management required should be obtained by trials. The light, when properly managed, exceeds any other artificial light ever yet produced."

Further on, at the last page of the book, the very last sentence runs as follows : "The quantity of electric fluid given out by the galvanic trough when compared with the quantity given out by an electric machine is worth attention. The deflagration of charcoal (experiment 209), which has been accomplished by the galvanic trough, has never been effected by common electricity."

Now, in those early years when Davy was showing this experiment at the Royal Institution, and other people were repeating it, there does not appear to have been any very careful distinction drawn between the mere spark obtained by breaking the circuit between the points and the continuous flame, which, as I have shown you, can be produced by putting the points together and then separating them. If I steady my hand on a stand and hold the points a little distance apart, I get a flame which persists, although the carbons no longer touch one another. If I merely put them together and separate them wide asunder, I get a momentary spark. It is not very clear from the records that the permanent flame, what we now call the arc, could be obtained ; it is rather implied than described. The term "deflagration," used by Cuthbertson to describe a phenomenon which could not, as he plainly says, be produced, as momentary sparks can, by "ordinary electricity," is decisive. However, from the year 1808, there is no question whatever on that point. It was in that year that Davy drew up a kind of circular, addressed to the managers of the Royal Institution, saying that he hoped great things in the relation of electricity to chemistry to come from the voltaic pile, and begging them, if possible, to provide the means for purchasing a much larger battery. As a matter of fact, that famous battery of 2,000 cells was obtained by private subscription, and with this battery of 2,000 cells it was that Davy produced the phenomenon that created so much attention—viz., the production of a permanent flame of a great length and dazzling brightness arching over from one piece of charcoal to the other. If one substitutes for the comparatively soft charcoal that Davy first used, and that the earlier experimenters used, one of the hard carbons of the modern sort, one can manage the flame a little more conveniently. It was well known from about 1820 that the hard carbon obtained from the inside of gas retorts was a really good conductor of electricity compared with charcoal and many other things. It was in that respect comparable to the metals, and, indeed, by Babbage and Herschel the hard retort carbon was actually classified amongst metals in conducting power. Hard retort carbons were introduced for the purpose of battery plates a little later by Walker, and about 1834 were used by Grove, when he wanted to employ nitric acid. He found that nitric acid would dissolve copper or iron or silver, such as had been used in some of the earlier voltaic cells, and he was compelled to employ some materials which nitric acid would not attack. He employed both platinum and retort carbon cut into slips. But his battery became known as a platinum battery, and when, in 1843, Bunsen returned to the matter and employed carbon, many people imagined that carbon was Bunsen's invention for the purpose. At any rate, the use of hard carbon was coming into use in the arts. Foucault, in 1843, found that hard carbon sawn in strips was a better material than charcoal for producing the arc light, and artificial carbons were being made. By this time Bunsen himself had suggested the moulding of materials for the making of battery plates. Several patents were taken out for making artificial carbons by Greener, Staite, and Jabez Church in England, and by Le Molt, Archereau, and several others in France. One finds, in fact, that the electrical industry was being provided with the very material required, a hard carbon of good conducting qualities. About 1844* Foucault definitely proposed the use of pencils of retort carbon for the purpose of making the arc light. It was in 1846 that the first mechanical arc lamp was combined by William Edward Staite. Staite was one of those men whose inventions miss fire by being much before their time. He not only devised the necessary mechanism for an arc lamp, but proposed, among other things, to use two carbons parallel to one another, exactly in the same fashion that Jablochkoff did some 30 years later. Staite made a number of suggestions and improvements in detail, but does not seem to have worked much at the phenomena of the arc itself. Others, however, worked at it ; Grove, the sole survivor of all the men of that time, happily still with us, not then a judge, made some experiments on the loss of weight of the carbons, to find out how much carbon was consumed by the light in a given time. He also tried other materials than carbon, and found that the addition of volatile matters, such as sodium or potassium or their salts, increased the length to which the flame could be drawn out without breaking when supplied from a given battery. Daniell made some experiments, and found, amongst other things, that if you took your carbons and produced the arcs and let the tips get very hot, and then separated them so that the light goes out, and bring them near together, they still do not light unless you bring them into actual contact for an instant. But Daniell found that they could be made to relight by simply passing the spark from a Leyden jar discharge across—to begin the discharge, as it were. This was rediscovered by several persons later : Herschel, Van Breda, and Fusinieri all claimed to have discovered the rekindling of the arc by means of a spark from a jar. I here repeat the experiment, using a little Wimshurst influence machine to charge a suitable jar. Even Hertz waves can kindle the arc under favourable circumstances. De la Rive experimented with the arc, and examined various other phenomena, including the beautiful rotation of the arc round an iron pole, under the influence of magnetism, which had first been observed by Walker. Foucault, in 1844, made the observation that if the current was passed to form an arc between carbon and silver the arc was unstable ; whereas if the arrangement was reversed, so that the current flowed from silver to carbon, a long and stable arc was produced, giving out that magnificent green light which is characteristic of the spectrum of silver. He made the acute suggestion that the stability of the arc depended on the volatility of the material used as poles. He also drew attention to the action of the heat of the arc in metamorphosing retort carbon from the anthracitic into the graphitic state.

Before I go any further I may mention several additional points that were discovered in those early years. One of the first things Davy discovered was that the arc would burn under liquids. I will take these two carbon pencils and dip them into a vessel containing paraffin oil. On touching them together and separating them, I obtain a fitful, uncertain light ; there is a great deal of heat produced and it gives off vapour, but as long as the oil itself remains cool, there is no fear of the vapour taking fire. The light is also toned down to a more agreeable golden tint than is the case when one takes the arc in air. If I put these carbons down into water, and in the same way make contact, I get a whiter arc, which also is still more fitful. A quantity of gas is given off, some of which is mere steam, which condenses very rapidly, some is hydrogen, some is oxygen, and there are some compounds of carbon and oxygen also given off.

Arcs Between Metal Electrodes.

Returning to the arc in air, if I were to replace one of the two carbons by a bit of metal, I should get a very different effect. It is impossible to get a very steady arc between two pieces of metal, or even between a piece of carbon and a piece of metal. The kind of arc one gets depends very much on the metal one uses, and also on whether one is employing a metal as a positive or a negative electrode. Here, for instance, I am using a carbon rod for one electrode, and a bundle of iron rods for the other. There is an arc between the iron and the carbon, and the iron deflagrates off in a beautiful way in a fountain of ruddy sparks. It looks much more dangerous than it really is. If I take

* *Comptes Rendus*, xviii., p. 696, 1844.

Digitized by Google

copper I get a very uncertain and flickering light, while the arc is of one colour if I employ the carbon as the negative pole, and another colour if I employ it as a positive pole. The copper disintegrates off more readily if it is made the positive pole than if it is made the negative pole. I am now employing solid iron; it does not deflagrate so much as the iron wire that I had before. Now I will take zinc, and I obtain this horrible roaring, hissing arc. But I may show you zinc under more favourable conditions. I will replace my metal electrodes by carbon ones, and take an ordinary stick of zinc, such as is used in battery cells. I will then make contact to it by touching it with these two carbons. If I make contact a moment with both, and then remove one of them, I shall have an arc between the carbon and the zinc. First, I will so operate that the zinc is the positive and the carbon negative. Then I will reverse the operation so as to have the zinc negative and the carbon positive. In one case the arc is much bluer than in the other, and it hisses much more. The arc is quieter if the carbon is positive, and the zinc negative than when the zinc is positive and the carbon negative. If I employ quicksilver in the same way, I shall obtain an arc which will differ in brightness according to whether the quicksilver is positive or negative. More vapour is given off when the quicksilver itself is the negative pole. The quicksilver now is positive—that is, a yellower light, and not so bright. The vapour is horribly poisonous, so we will not continue the experiment long. Prof. Way, an inventor of a mercurial arc lamp, 30 years ago lost his life by the poisonous fumes.

Arcs and Sparks.

Many of the earlier experimenters are extremely vague in the way they describe the arc. They do not give definite statements about the actual amount of the current they employed, and one can only judge of the E.M.F. at their disposal by counting the number of cells, and trying to find out what sort of cells they had. Modern science gives us the opportunity of being more precise. We can say exactly what E.M.F. we are using, and how much current we are actually sending through an arc. Such arcs as we have in modern practice require an E.M.F. of something more than 20 and something less than 70 volts—varying generally from 40 to 50 in the case where continuous currents are employed. Under those conditions the arc produced is a very different phenomenon from that which is produced by sending a much smaller current at a much higher pressure; for then the discharge takes the form of a thin spark. If one sends a spark or a succession of sparks from an induction coil, or from a large influence machine between two brass knobs at a distance from one another in the air, the discharge that one gets resembles the arc to some extent, but really is a very different phenomenon. The discharge one gets in vacuum tubes, between terminals of platinum, across the highly attenuated air, is again a different phenomenon. For in neither of those two cases does the material of which the electrodes are formed play any important part in the phenomenon. In these cases, as we now know, from the recent researches of Schuster and of J. J. Thomson, there occurs an electrolysis of the gaseous medium. What you produce in these cases is a discharge carried on by gaseous particles, which move about no doubt and pass to and fro and shine, but the light mainly comes from the volatile or gaseous particles, and does not come from the solid matter which constitutes the electrodes; whereas in the true arc itself the main light comes from the solid matter of the electrodes, and not from the gaseous matter of the flame in between. So in the production of the arc, a great deal depends—in fact, everything depends—on what that solid matter is. By universal consent carbon is found to be the only workable material. Moreover, the carbon is consumed at one or both of the electrodes during the continuance of the arc. This circumstance alone constitutes a distinction between the two cases. Now, the normal sort of arc produced between two carbon pencils is a thing that will engage our attention far more than any other arc, because it is the normal arc produced between two carbon pencils which is of industrial value. The others are mere curiosities, so to speak; they may hereafter have an industrial interest, but at present they have only an abstract scientific interest.

The Normal Arc.

What, then, are the conditions of producing the normal arc? We have carbon pencils of the purest and best carbon one can obtain. In most cases one wants a good conducting carbon, and a fairly hard one. The pencils must be put together, and after having been put together, they must be separated to the requisite distance; then the flame springs forth. In technical language, "the arc is struck." The tips become brilliantly white hot: one of them—viz., the positive one—burns away faster than the other. They assume different shapes, and the light is found to come almost entirely—by far the greater part of it, at any rate—from the white-hot end of the positive carbon.

To examine the conditions of the arc, a lens is arranged so as to throw a magnified image of the arc on the screen, where we can see the shape without being blinded. You will now see in the image on the screen what justifies my statement that the light does not come from the flame in between the two. The arc is now burning steadily, and silently; the current being sent in so as to flow downwards. The top carbon, which is therefore the positive electrode, is seen (Fig. 1) to have assumed a flattened form. That is the form assumed by the positive electrode, after being allowed to burn for a few minutes. There is a sort of slightly hollowed crater full of light. The current is coming out from that crater into the flame. There is an almost invisible pale-blue flame in between the carbons. The lower pencil has taken a more pointed form—a sort of peak having formed upon it. This negative peak also shines white hot, but we do not get so much light from it as from the other, nor is its light so white in quality. If I hold the carbons at a proper distance apart, you will notice that the arc burns quite quietly, and we have a silent flame. If I were to pull the top carbon up too much, and make the arc too long, it would begin to flame more and to roar, and would probably go out. On the other hand, if I make the arc too short, it would begin to hiss.

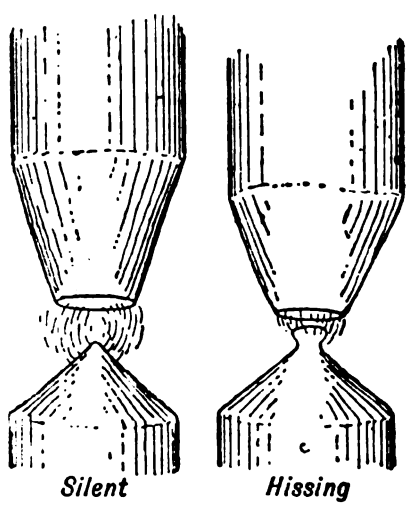


Fig. 1.

Sometimes it hisses persistently when the arc is too short. You then notice another phenomenon taking place—viz., that the negative tip, which ought to be burning away while keeping of a peaked shape, acquires little lumps. There are little projections, technically known as "mushrooms," which appear upon the peak. These mushrooms always occur when the arc is hissing. When the arc is burning silently the mushroom disappears, burning away until the negative carbon comes to its proper conical shape. In the case where alternating currents are used there is no such difference in shape between the two tips, as we shall see in due course. For the present I am considering the arc as produced when the current is of the continuous kind.

There is some difference in the circumstances attending the production of the normal arc. In America, the practice is to use two pencils of equal size, and of the same quality of solid carbon, usually coppered, and to work with arcs about 1-10in. long for a current of 10 amperes, many lamps being run in series. In England, where parallel running of lamps or groups of lamps is more common, the practice is to use as upper pencil a carbon of larger size than that employed for the lower pencil, and the upper carbon is usually "cored" (*i.e.*, made tubular and filled with a core of softer quality); while the length permitted the arc seldom exceeds 1-16in. to 1-12in.

Now, there is a great difference in properties between the arc that hisses and the arc that is silent. Not only have you this characteristic difference in shape, but the light is distributed differently from the surface. The quantity of current consumed, other things being equal, is different, and, in fact, as I shall show presently, the conditions are completely changed. Now, I would like you to contrast the effect produced in an arc burning quietly in that way with what one gets if one tries to form a current between two carbons in the same fashion at a distance from one another, using also a steady current, but employing much greater E.M.F. I have the means here, by a small continuous-current transformer, of generating a small current of about one ampere, at a pressure of 1,000 volts. The wires from that small continuous transformer are joined up to two carbons here. This long flame is obviously quite a different thing from what one gets by using the same amount of power in the form of a larger current at a smaller pressure. It is totally different from a 10-ampere arc at 100 volts, or a 20-ampere arc at 50 volts. There is a little streak of light, but that is really more of a flame colour, and the light from the carbon tips is comparatively insignificant.

Relations between Voltage, Resistance, and Length of Arc.

As soon as electricians began to think about making arc lamps, they had to discuss how much current to provide, and

Digitized by Google

at what pressure. They had to decide as to the thickness of the carbons that was required, and what length they must allow. In fact, they had all manner of things to find out, and amongst the things they did experiment upon was what was the relation between the E.M.F., the current, the resistance, the length of the arc, and the size of the crater. They came across a very strange fact. If you consider the arc as a conductor, as a column of flame, or vapour conducting the current, you will find that it does not follow the laws of ordinary conductors; when you double its length it does not offer twice the resistance. It was a very puzzling fact, and the Swedish physicist Edlund, who first drew attention to this fact, thought it could be explained by supposing that in the arc itself there is a sort of polarisation as there is in a secondary battery when you are charging it, or as in a voltameter when you are decomposing water.* This polarisation manifests itself as a back E.M.F. opposing the current. Many researches have been made upon this matter, and I have tried to tabulate them:

FORMULÆ SUGGESTED FOR THE ARC.

Edlund	$r = a + b\,l$
Edlund	$V = C\,a + C\,b\,l$
Ayrton and Perry*	$V = 63 + 2{\cdot}1\,l$
Frölich	$V = m + n\,l$
S. P. Thompson	$V = m + \frac{n\,l}{C}$
Mrs. Ayrton†	$V = \alpha + \beta\,l + \frac{\gamma + \delta\,l}{C}$

* Their formula had a small correcting term here omitted.
† Added since the delivery of the lecture.

VALUES OF THE CONSTANTS m AND n (l BEING EXPRESSED IN MILLIMETRES).

Authority.	Date.	m.	n.
Ayrton and Perry	1882	63	2·1
Frölich	1883	39	1 8
Penkert	1885	35	1 9
Von Lang	1885	39	—
Von Lang	1887	37	—
Cross and Shepard	1886	37 to 39·7	1 9
Luggin	1887	40·04	1·77
Uppenborn	1888	40·1	2·24
Duncan and Rowland	1892	40·6	1 6

The E.M.F. applied to the arc to drive the current through we may call V. It may be otherwise described as the difference of potential across the carbons. Edlund found it to consist of two parts, a part independent of the length, and another proportional to the length, l, which symbol, in these formulæ, stands for the length in millimetres. As Edlund wrote the formula, it was an expression for the apparent resistance, r, in terms of the length, l, and two constants, a and b. This we may transform into an expression for the voltage, V, by multiplying both terms by the current, C, as in the second line in the above table of formulæ. The terms $C\,a$ and $C\,b$ are respectively the same things, as are denoted by m and n in the formula used by Frölich. They simply mean that the voltage consists of two parts, one a constant, the other varying (like a true resistance) with the length of the arc. Edlund did not himself determine the numerical value of those constants. They were not determined, as far as I know, until 1882 or 1883, and the earliest determination of that constant and the variable part is, so far as I know, due to Profs. Ayrton and Perry, but I do not understand the figures in their paper, because they make out that the constant part is 63 volts, and the part which is proportional to the length is in volts 55 times the length in inches, minus a correcting term (omitted from the formula for simplicity). The diagram which they gave, which corresponds to these figures, is to me entirely unintelligible, unless one supposes that in 1882 the voltmeters employed measured the voltages nearly twice too high. The other figures here given, with their dates, show a much more consistent tale: Frölich, in 1883, found the fixed part 39 volts, and the variable part to be 1·8 times the length of the arc in millimetres; Von Lang found 39 or 37 for the fixed part; Penkert found 35; Cross and Shepard 37 to 39·7; and Luggin over 40.

If we take 39 as about the average of these we shall not be very far wrong. Now, these 39 volts that one finds as the fixed part apparently having something to do with the properties of the carbons, for if you try arcs with any other material than carbon you get also a fixed number, but a very different one. And if you put into the carbons any other material to make them longer—for instance, soda, potash, alumina, or any metallic salt or metal—the maximum flame may be longer under different conditions, but as a matter of fact the light will be less for a given consumption of energy, and the fixed part of the voltage will also be less. Probably these low numbers of 35 and 37 are due to the presence of impurities in the carbons.

Now I should like to illustrate this matter by a diagram or two, in which some of these researches are set forth.

* Edlund considered that he had proved by experiment the existence of a measurable polarisation a fraction of a second after the current had been cut off. Although this persistent back E.M.F. was confirmed by Latchinoff, more recent experimenters, such as Stenger and Luggin, deny its existence.

Fig. 2 is a diagram illustrating the results of Frölich's researches. The length of the arc from the crater to the peak is plotted out horizontally, the voltage is plotted vertically. In the shortest arc which could be used without hissing Frölich found about 40 volts to be the amount of the E.M.F. which maintained the arc. As he lengthened the arc the voltage went up in this slightly irregular way. The irregularities may be due either to bad quality of carbon or to the circumstance that the current was not maintained constant, or possibly to the experiments being made too rapidly to allow the arc under each of the successive conditions of length to burn long enough

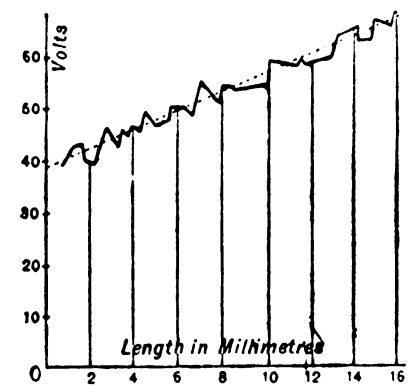

FIG. 2.

for the electrodes to assume the forms which they would acquire if left long enough. You will note that this curve slopes as though it intended to come down to 39, when the arc is of no length at all. To make a flame of this sort carry a current across from the positive to the negative carbon requires 39 volts, and the additional voltage indicated by the additional height to any point on the sloping line is that which is necessary to drive the current through the flame when the flame has various lengths. The longer the flame the more are the additional volts required.

Fig. 3 relates to some of the researches of Cross and Shepard. These researches are in many ways very full. For the first time statistics are given, not only for silent arcs, but for hissing ones. They made a number of determinations, trying various kinds of carbons, and also tried the effect of putting in different materials, such as soda and potash. The experiments shown in this figure relate to one particular kind of carbon, but using currents of different strengths; one set when using a current of five amperes, another when using 7·9 amperes, another 10 amperes; and they found that if they pursued the thing down, beginning with a long arc, and gradually shortening it, and

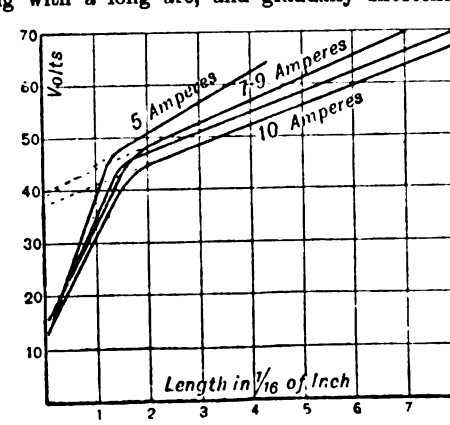

FIG. 3.

adjusting the current to the same amount as before, that the voltage fell, in all cases, as though it intended to go down to 39 volts, when the length is reduced to an appreciable amount. But as soon as the arc begins to hiss, then the curve changes; there is much less E.M.F. required to maintain the hissing arc than the silent arc, and the hissing arc appears to point somewhere to 15, 14, or 13. The hissing arc is very unsteady, however, and the exact form of the curve is uncertain here. To maintain a hissing arc wants very much less E.M.F. than to maintain a silent arc of no appreciable length; but in each case there is a part of the voltage fixed, and a variable part depending upon the length of the arc. I might give you, in similar curves, the results of nearly all these experimenters; but I should be only giving you the same thing over and over again.

I have found that, by gently blowing sideways on the arc, so as to cause it to take a long curved path, its resistance is increased: it then requires a higher voltage to maintain the current. The arc is indeed curiously sensitive to winds and draughts. It can quite easily be blown out like the flame of a candle.

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

BRIGHTON TO ROTTINGDEAN.

From the very first inception of the project to the present time our readers have been made acquainted with the fortunes of the proposal to connect Brighton and Rottingdean by an electric tramway. Many years ago Mr. Volk designed and constructed an electric railway or tramway at Brighton which runs parallel to the Madeira-road. Knowing that a large summer traffic exists between Brighton and Rottingdean, he naturally looked into the matter of continuing the existing line to Rottingdean. That, however, was not deemed feasible, and another scheme for a line commencing but a few yards from the existing line was adopted, a company formed, and an Act of Parliament duly obtained. The proposed line will, for the greater part of the day, be under water, and at high spring tides the rails will be fourteen or fifteen feet below the surface. It may truly be described as a line under the sea. Ordinary tramway conditions do not apply in such a case. Originally it was thought that the car might be self-contained, carrying accumulators and motors, the latter communicating with the wheels of the car through gearing. We gather, from recent developments of the matter, that the idea of accumulators has been given up, and the scheme now favoured is to use the trolley system. Sanction for the erection of poles for this system has to be obtained from two or three authorities, and according to our information such sanction has been obtained for the line except the part under the jurisdiction of the Brighton authority. The most recent reports, discussions, and conclusions of this authority are given elsewhere in our columns. We have not to decide the question for Brighton, and we have no doubt but that permission will be given for the erection of the necessary poles. Usually a council will only consider a new scheme submitted for their approval as regards its being a nuisance or a danger. Brighton, however, must also consider the value of the completed scheme as an attraction to the town. We quite understand that a certain influential population of the town condemns everything in the way of attraction. They would have a quiet, residential, seaside resort; they would abolish excursions and excursionists. Those views are excellent in their way, but unfortunately it is too late now to keep Brighton select; and as a very large part of its wealth and prosperity is due to the expenditure of excursionists and visitors, their wishes must be considered. Now, visitors do not go to Brighton to sit in their hotels or lodging-houses, and there must be something for them to do. Some go the Devil's Dyke, some to Rottingdean, some on the water, some on the pier, and so on. Surely the ability to go to sea on a kind of moving pier-head, to be surrounded by water and pure air without danger of sea-sickness, to go on a unique kind of railway, forms just one of those attractions a popular sea-side place requires. Blackpool rejoices in its Winter Gardens, in its Eiffel tower, and will, ere long, rejoice in its big wheel; but then Blackpool acknowledges its indebtedness to visitors. Brighton, in part, wishes these visitors

Digitized by Google

at the Dyke. Of course, the people on the spot are those in the best position to speak of nuisance and danger. From our own knowledge of this part of the Brighton beach, we should say that the nuisance from the proposed railway would be a minimum and the danger nil; while, again, the convenience would be great. No doubt a considerable part or weight of opposition to the scheme emanates from cab proprietors, and their views ought to be considered. They, no doubt, think that many carriages now hired to go to Rottingdean would not be required if the railway was in competition with them. This view is, we think, erroneous. The class of people who ride in carriages is not the class that ride in tramway cars. The increased accommodation would lead to increased numbers going to Rottingdean, and with increased accommodation there, in the shape of a good hotel, or good tea-gardens, the hire of carriages would probably in the long run increase rather than diminish. With regard to the details of the scheme. Being somewhat unique, it was but natural that some of the details would undergo alteration as the work progressed. This has occurred: the outside rails are now only eighteen feet apart, as against twenty-four feet originally contemplated; the car is increased in size and weight—hence the power for its propulsion is greater than was spoken of at first. Of all the means of supplying the fluctuating power required for tramway work, the electric trolley or conduit are the best. In this case the conduit is impossible, while the trolley is convenient and practical. By it you can convey all the fluctating power required. There is little noise and no nuisance attached to its use. We are pretty certain that neither compressed gas nor oil can be used with so little nuisance, and under the circumstances we doubt the practicability of using either gas or oil. From the æsthetic point of view, a post here and there is no more a nuisance than the mast of a boat or masts of boats in the foreground. From another point of view, Brighton having the credit of being the first place in this country where an electric tramway was inaugurated, should be glad to further add to its laurels in being the first to patronise another unique scheme of electric traction.

CITY AND GUILDS EXAMINATIONS REPORT.

The annual report of the Examinations Committee has been issued, and gives the usual statistics relating to classes, students, candidates, successes, and failures—marking time by reporting progress. A few sentences culled from the abstracts of examiners' reports are, however, of more interest than the statistics and conclusions founded thereon. In telegraphy and telephony, we are told, "the general results may, perhaps, be not considered to be so good as they were in 1894, yet the very satisfactory answers given by the best (a large number) of the candidates has rendered the examination a decidely creditable one." Often the candidate fails, not from want of knowledge, but from injudicious questions set by inexperienced examiners. In this case the fault is not with the examiners. The questions set are such as ought easily to be answered correctly, and if not satisfactorily answered by the candidate he ought to fail. The examiners in "Electric Lighting and Power" are somewhat hard upon their candidates, and here we think the fault is with the examiners themselves. Three or four of the questions are hardly of the kind we should expect to be set to young students at a preliminary examination. On the other hand, the candidate has a large selection of questions, and ought to be able to gain full marks without answering the doubtful ones. We always prefer the system of grouping questions on the same branch of the subject, and permitting a selection from each group. Otherwise, the candidate may gain full marks by ignoring altogether one or two important sections of the syllabus. In this particular paper the preliminary syllabus consists of nine sections. Why not put the questions in nine sections of three to a section or two to a section, giving full marks only when one at least in each section is correctly answered? The examiner in mechanical engineering makes one or two remarks very much to the point. We should be inclined to agree that many of the candidates have never been inside a workshop; also in the remarks that "there is considerable evidence of the attention of the candidate being strictly confined to his subdivided branch of work." It is a very difficult subject to suggest a remedy for this state of things. In many factories each man works year in and year out at one particular bench at one particular class of work. He becomes expert and experienced in this particular work, and knows practically nothing of the why and the wherefor of any other branch of work in the factory. Hence, in an examination, his special knowledge must be prominent, and his general knowledge usually of the weakest. We cannot say more on this subject at present, but would impress upon teachers the necessity of carefully studying the examiners' remarks, and taking to heart the lessons contained therein.

REVIEWS.

Polyphase Electric Currents. By SILVANUS P. THOMPSON, D Sc., B.A., F.R.S. E. and F. N. Spon.

This volume is the outcome of a series of lectures on the subject delivered at the Technical College, Finsbury, in the autumn of 1894. The author states that a good deal of matter has been added, and that he is indebted to the various firms and designers for valuable information as to recent progress and modern types of machines. From a cursory glance, the reader is at once struck by the numerous abstracts from various authorities on the subjects, and on reading more closely he will be confused by the absence of explanatory notes to many of these abstracts. In fact, while acknowledging the value of a volume collecting, as the one before us does, the opinions and theories of notable workers on polyphase currents, we hold that a text-book on a definite subject should at least show sufficient mark of the individuality of the author as to use the same methods of mathematical treatment in developing the different steps of the theory of the subject. In the present volume the elementary theory of the polyphase motor is commenced by a few pages of simple algebra, presumably by the author; we then pass to an abstract from Mr. Gisbert Kapp's last edition of "Electric Transmission of Energy," where graphical methods are employed; then the conclusions of Steinmetz

Digitized by Google

are given without proof, and we pass on to the analytical theory based on the work of Mr. A. Potier, where integral and differential calculus is employed. Again, with the theory of monophase motors, we find three methods of treatment are employed, but here each is more complete in itself. The author commences by assuming that the reader already possesses technical knowledge, and hence much valuable space is saved. The first chapter deals with polyphase generators. It contains a good detailed description of the historical three-phase alternator used at Lauffen for the transmission of power to Frankfort. A dimensioned section of the revolving magnet and armature is given. Generators made by Brown and Boveri, the Oerlikon Company, and the Westinghouse Company are also illustrated, but the only other useful section shown is one of the 5,000 h.p. generator used at Niagara, which is taken from the *Journal* of the Institution of Electrical Engineers. It is in the next chapter, which is on the combination of polyphase currents, that the want of editing in the abstracts becomes more noticeable. Thus, on p. 50, a conclusion from a French book on the same subject is quoted to prove that a common return wire with the two-phase system increases the difference in phase between the two circuits. The reader is led to infer that the shifting in phase is due to the resistance of the line. We doubt the fact, and also are sure, that the illustration referred to as showing the connection—*i.e.*, Fig. 49 has no common return wire in it. Further on, when treating of the economy of copper with the various systems, we come to the following novel assertion on p. 55: "If, on the other hand, we take the maximum pressure between any two lines as a basis of comparison, we are now equating, not the risks of breakdown of the lines, but the risks of breakdown of the apparatus, machines, transformers, etc., in which the goodness of the insulation must be considered equal." No authority is given for this statement, so that we presume it is original, but the author does not bind himself by the "considered equal goodness." He proceeds to discuss the matter as though the risk of breakdown on the line was, after all, a function of the maximum pressure. A few pages after this we find an abstract from a paper by Mr. Goerges on the same subject which is unintelligible without more context. Chapter III., dealing with the properties of rotating fields, is historically interesting, and contains descriptions of some ingenious lecture models. This is followed by a chapter on the early development of polyphase motors, in which the author is quite at home. It commences with a description of Mr. Bailey's model, made in 1879, on the Arago principle, and gradually merges into a series of cuttings from patent specifications, illustrated by drawings taken from the same sources. The chapter ends with a good account of the Lauffen-Frankfort transmission of power scheme. The structure of polyphase motors is then discussed, and the useless endeavour to use the old terms "armature" and "field magnet" for rotary-current machines is wisely abandoned. The terms employed instead, "rotor" and "stator," must, of course, be considered to apply strictly to the moving and stationary parts respectively, although generally the alternating currents are supplied to the stator. Some useful hints on the practical construction of such motors are deduced from the commercial Continental types, one of these being the fact that the conductors on the rotor and stator should not be symmetrical in number or position. The chapter on the elementary theory of these motors we have referred to above. The theories given of the monophase motors, although perhaps the best available for abstraction, are not built on satisfactory assumptions. A few types of two and three phase transformers are described, and then the problem of a means of converting two-phase currents into three phase is treated. The method is simple, and consists of a ring of laminated iron provided with internal radial spokes. A rotary field being produced in the core, it follows by sequence that windings on different parts of the ring will have E.M.Fs. of varying phases produced in them, according to the relative positions of the coils. This idea is claimed by the author as being first published by him in February, 1894. It is a natural deduction from the patents of Bradley, Tesla, and others, for converting direct currents into alternating currents of different phases. We then come to a method by M. Désiré Korda which is stated, in the heading, p. 182, to convert monophase currents into currents of two or three phases. The next line contradicts this statement, and says it has the same function as the author's own device. From the mathematics, we gather that the inventor hoped to get the first result, but the apparatus as described will certainly give neither a constant phase-difference nor E.M.F. with varying loads. Perhaps the term "movable self-induction coil," which is said to be employed, does not mean that the coil is portable, but rather that the self-induction used is varied by hand as the load changes. The important subject of the measurement of polyphase power is dismissed by a chapter extending over 2½ pages, and the author then gives some notes on the design of rotary-field motors. As these are based on a motor actually made by the Oerlikon Company from the designs of Mr. C. E. L. Brown, which is illustrated by an end view and section, they repay close study; but it must be remembered that Mr. Brown's connection with the Oerlikon Company ceased in 1891, so the design cannot be up to date. The next chapters deal with the mechanical performances of these motors, and descriptionss of starting devices. The tables of tests are supplied by the makers themselves, and hence must be taken *cum grano salis*. The details of more recently-designed Brown motors which follow are decidedly useful. The appendix, which comes after the last chapter, contains 17 pages of references to literature on the subject from books and papers all over the world, and we note that the *Electrical Engineer* has not, in the author's opinion, added anything to the readable literature.

A second appendix, giving a list of patents, will be convenient should the legal right to manufacture polyphase currents ever be fought out in England.

COMPARATIVE COST OF ENERGY IN CENTRAL AND PRIVATE PLANTS.

Prof. Zickler discusses the comparative cost of electric energy from private installations and from central stations. Among a number of deductions he gives a diagram which shows that for an installation of 150 incandescent lamps of 16 c.p. consuming about 50 watts per candle, running for a mean of about 600 hours per year, it is cheaper to obtain the energy from a central station, while for 400 lamps of the same kind and running 1,000 hours per year, a private installation running with gas-motors is more economical. If there are 100 lamps running 1,000 hours per lamp per year, the diagram shows that for a consumption of one cubic metre of gas per horse-power hour the central station is more economical, for 0·9 cubic metre the two systems are alike, and if the consumption of gas is as low as 0·8 it is more economical to put up a private installation.

BRIGHTON AND ROTTINGDEAN TRAMWAY.

The following is a brief description of this line, which is now causing a considerable amount of discussion on the Brighton Town Council.

The line commences at the eastern end of the electric railway, Brighton, and extends a distance of three miles to the village of Rottingdean, a favourite summer resort. Here a small iron pier has been erected for the cars to run alongside; the pier is available for steamer traffic and promenading. At the Brighton end of the line an iron jetty has been erected, and a building containing commodious waiting-rooms and offices has been erected on it. The rails are laid on concrete block (made *in situ*) spaced about 3ft. apart, morticed into the sound rock, the height of the blocks varying with the irregularities of the shore. A shifting sand of very moderate depth covers the rock in places; the rails, however, have been laid sufficiently high to prevent any trouble from accumulations on the rails.

Digitized by Google

The steepest gradient is 1 in 300, and the radius of curves 40 chains.

The line consists of four rails (54lb. per yard) laid as two tracks of 2ft. 8½in. in gauge, spaced 18ft. between outer rails, thus giving an effective gauge of 18ft. This is rendered necessary to give the required stability to the cars. The rails are secured by steel clips and bolts, the latter being embedded in concrete; oak blocks, through which the bolts pass, being placed between the rails and the concrete blocks. Tie-rods are also used every 10ft. on the straight and every 5ft. on the curves; heavy angle fishplates are used for the rail joints; the rails are in 30ft. lengths. The section of the track, and showing the proposed trolley poles, is shown in Fig. 1, which also shows a plan of the portion of the line within the boundary of the borough. The depth of water over the rails at high tide is about 15ft. Although the most violent gales experienced for many years occurred during the winter of 1894-5, no damage whatever was done to the permanent way, so the fact that it possesses ample strength to resist the force of the sea has been demonstrated in a satisfactory manner, and no accumulation of seaweed, etc., has taken place at any time.

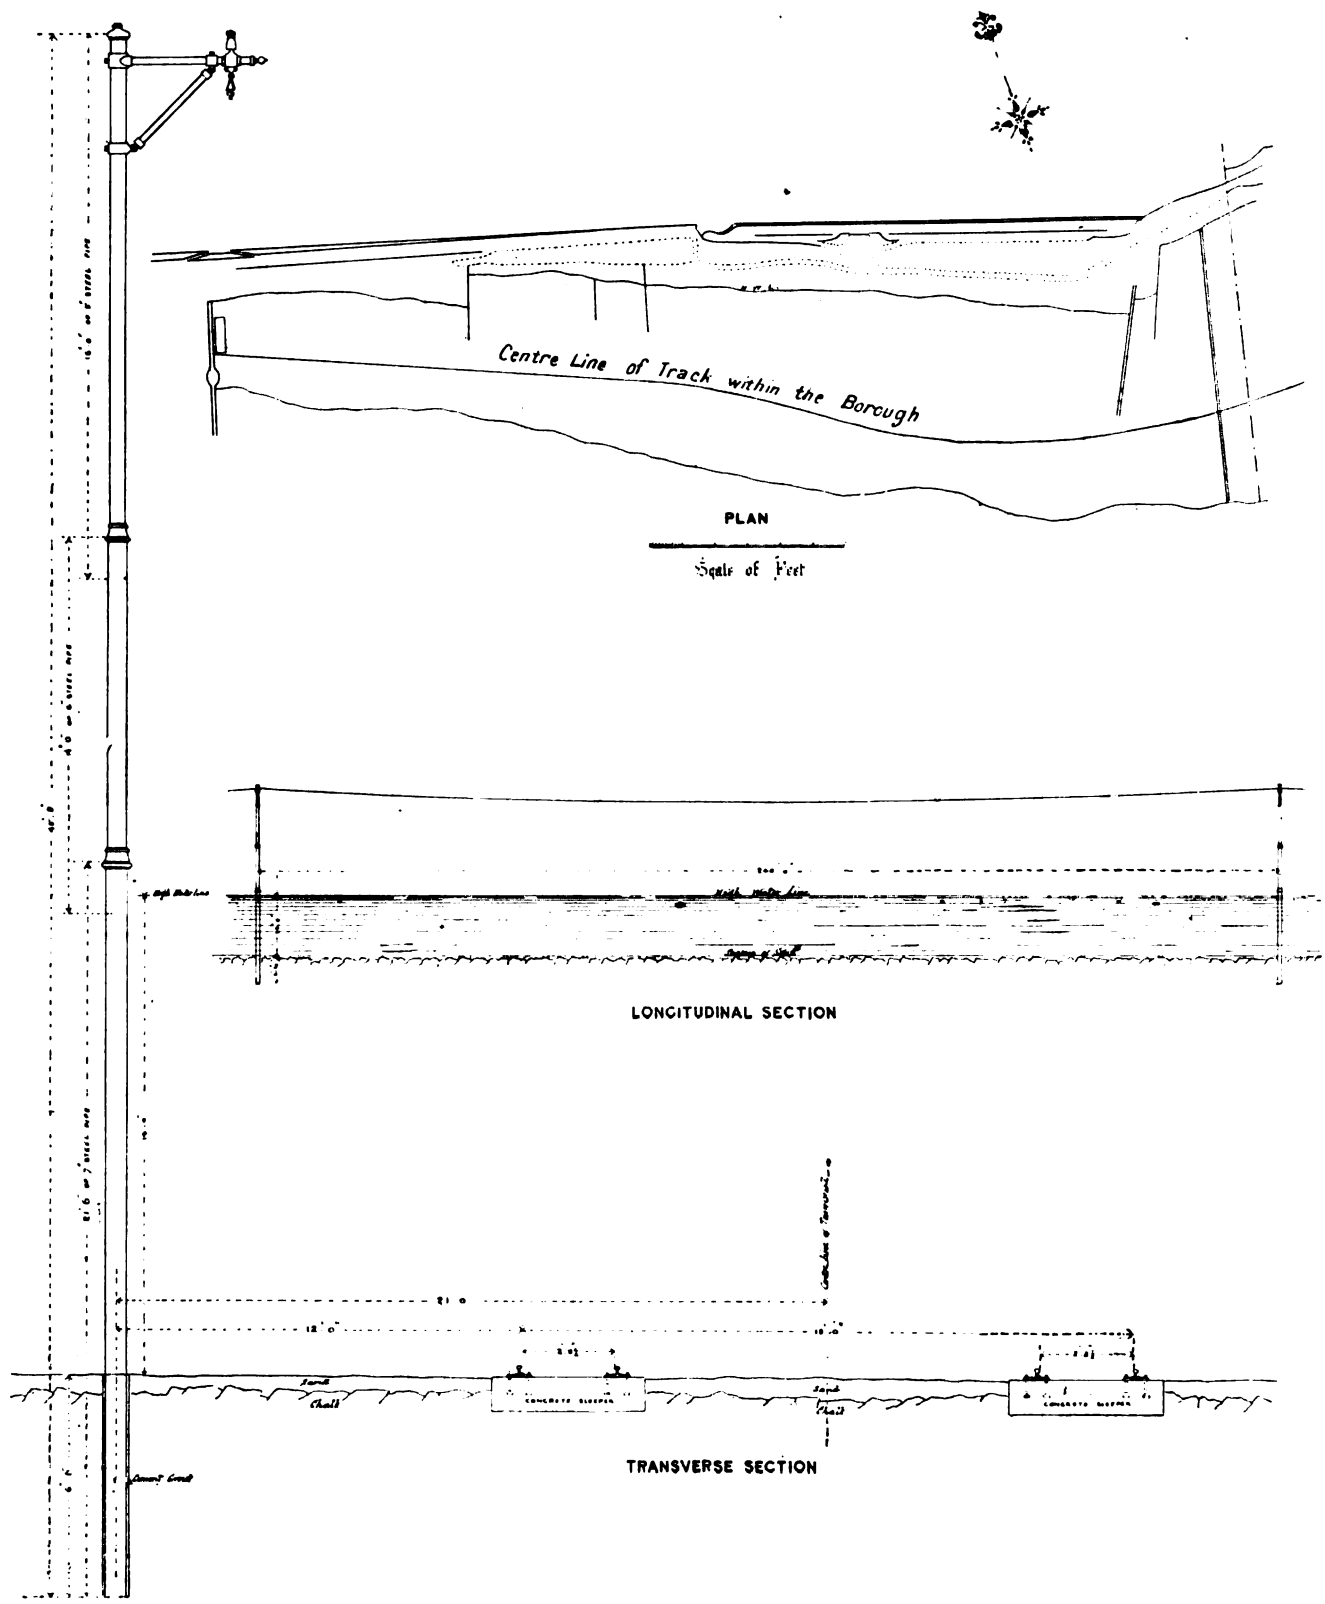

FIG. 1.—Sections of Track and Details of Trolley Pole Connections.

The line is now practically completed, but the work, being tidal, has been greatly delayed by bad weather.

The car (Fig. 2), which has been built by the Gloucester Railway Carriage Company, is a structure carried on 16 wheels, 33in. in diameter. The main deck for the passengers is at a height of 24ft. above the level of the rails. The four main legs are tubes of drawn steel, 11in. in diameter. At the bottom of each leg is placed a bogie truck having four wheels, the outside of the bogie being shaped like an inverted double-

Digitized by Google

ended boat, to facilitate its passage through the water, and also to remove any obstructions from the rails. The four bogies are firmly held together by steel tubular struts. The wheel base, about 28ft. long and the effective gauge 18ft., round and forms a promenade deck, seats being placed over the glass dome and over the centre of the saloon. On this upper deck will be placed the controlling apparatus for driving and stopping the car. As the journey, in short,

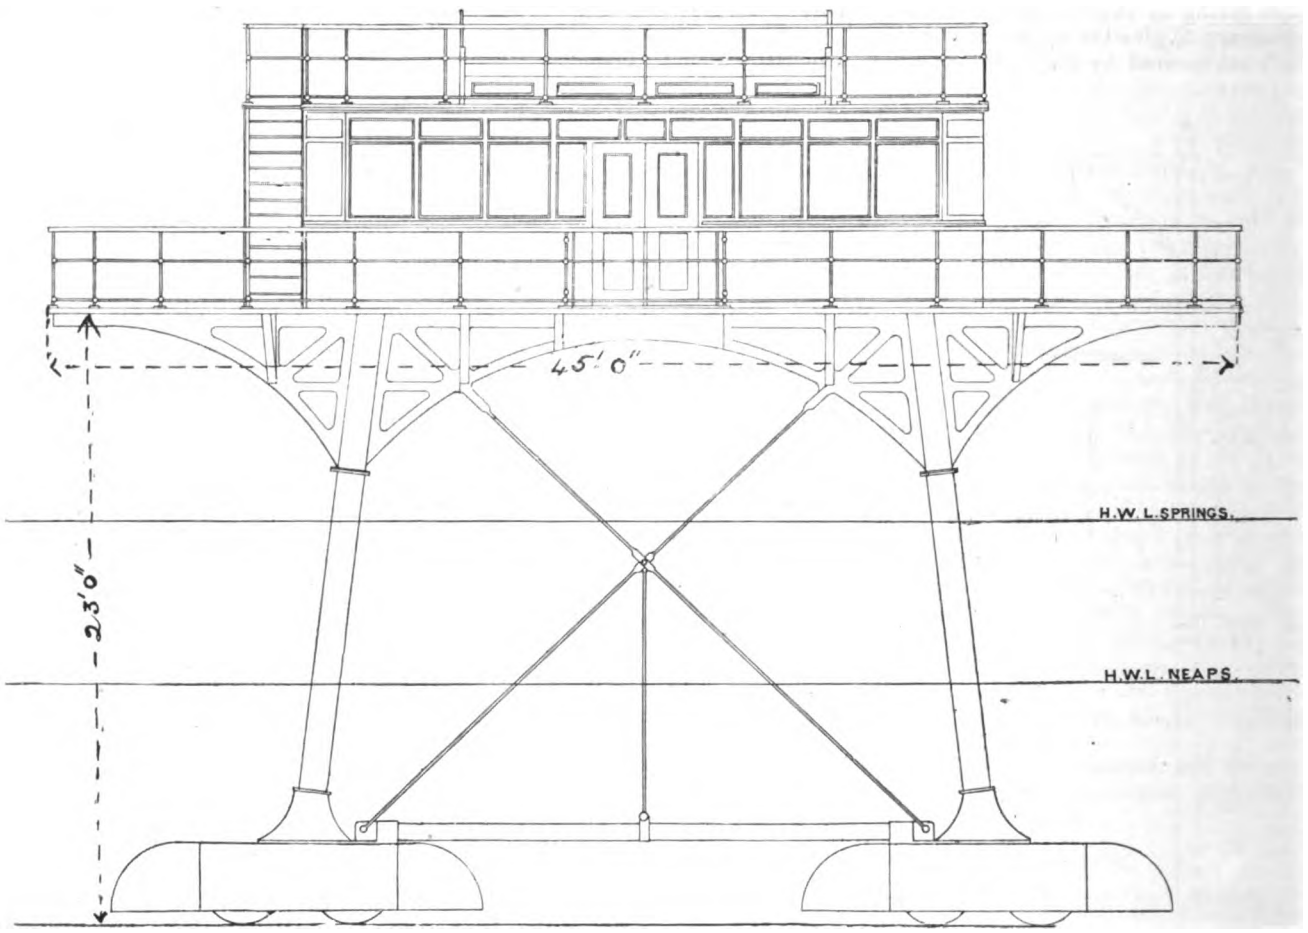

FIG. 2.—Side Elevation of Car.

give great stability to the car. The top of the main legs are firmly built into lattice girder work carrying the deck, and the whole structure is firmly secured by cross-ties. It is of great strength, although offering but a small surface to the force of the waves. The main deck appurtenances and erections will be undertaken more for the sea air than for quickly making the trip, it is proposed to keep the speed between six and eight miles an hour.

The driving machinery will consist of two 30-h.p. electric motors placed vertically over two of the main legs, one on

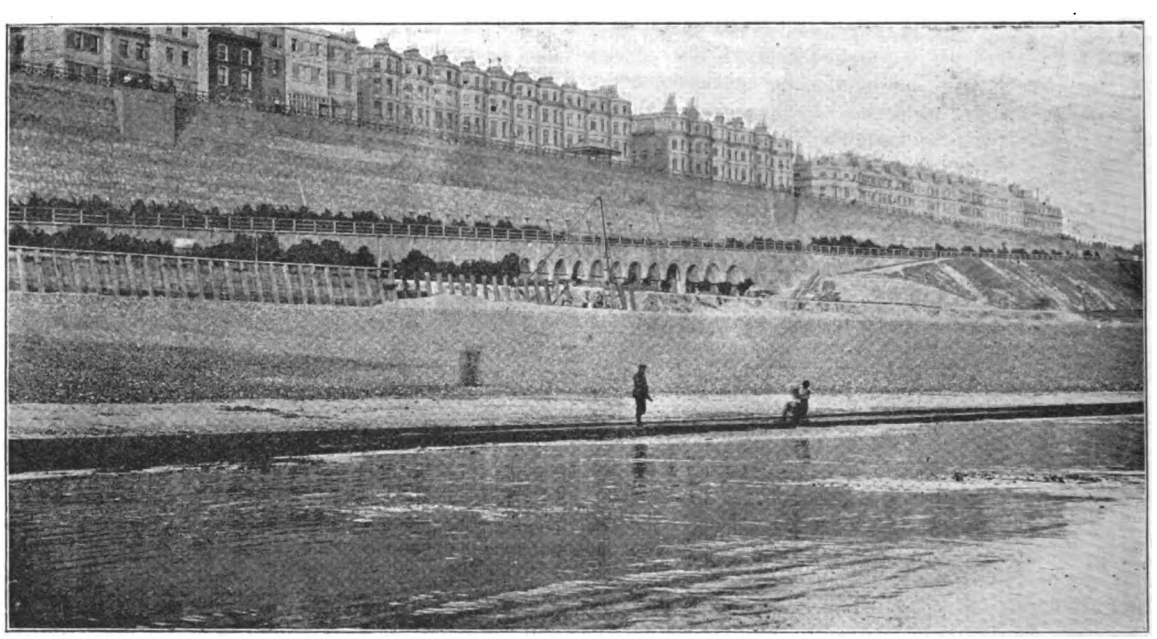

FIG. 3.—View of Track within the Corporation's Boundary.

are carried out exactly as if for a steam yacht. The deck measures 50ft. by 22ft., the railings round the deck being of iron with a wooden top rail and wire netting. The centre space of the deck is occupied by the saloon, a structure 12ft. wide by 25ft. long. The roof of the saloon is railed each side of the car, the shafting being carried down inside and communicating with toothed gearing which actuates the wheels. The brakes are worked by rods passing down the remaining two legs. The current, at 500 volts, will be conveyed to the car by means of a trolley pole and overhead

Digitized by Google

wire, provided the consent of the Corporation of Brighton be obtained for the portion within the borough.

Fig. 3 shows a view of the track and foreshore within the borough boundary, from which the reader can gather an idea of the surroundings, which certainly will not be prejudicially affected by the erection of ornamental poles 80 yards apart.

At the meeting of the Brighton Council on November 1 various reports concerning this tramway were considered. Those of the borough engineer (Mr. May) and the borough electrical engineer (Mr. Wright) arise out of the application of the company for permission to carry their wires on poles. The Works Committee had written to the Board of Trade calling attention to the matter, and enquiring whether the Board had required the car to be so increased in strength as to make the weight of the car quite double what was originally contemplated, the company alleging that this extra weight necessitated the use of the poles. The reply came in the form of a copy of a letter which had been addressed by the Board to the company in the matter. In this letter the company were asked: 1. What is the weight of the car as now being constructed? 2. In what manner, and at whose request, the design of the car has been altered so as to increase its weight? And 3. The number of passengers to be carried (*a*) in the original pattern car, (*b*) in the pattern now proposed?

The Works Committee also instructed the surveyor and the electrical engineer to draw up reports on the subject, and the documents are appended, the first being from Mr. MAY, the borough surveyor:

"In obedience to your command to place before you all the facts relating to the construction of this tramroad, I beg to say that when the promoters first submitted for your consideration the Bill by which they proposed to seek for parliamentary powers to construct their tramroad, and the plans which are always deposited with such Bills, your committee were distinctly informed: 1. That there would only be two lines of rails, about 26ft apart. 2. That these rails would only project 4in. above the surface of the chalk, or sand, forming the foreshore or beach. 3. That the line would not interfere in the least degree with the construction of any new groynes, as it could easily be carried over any such groyne, or round the south end of it at any point. 4. That the car would be of light construction. 5. That the car would be easily driven by electricity from accumulators carried on the car.

"If these arrangements had been adhered to there would have been: (*a*) Practically no risk to bathers or boats (*b*) The groyne at Black Rock would have been constructed as originally designed and approved by the Town Council solely as the best method of protecting the eastern foreshore. (*c*) There would have been no obstruction to the free use of the sea, nor anything visible above the water.

"The original proposals have been departed from in the following particulars: (1) There are four lines of rails about 18ft wide between the outside rails. (2) Without having first obtained the sanction of the Town Council, the minimum projection of the rails above the chalk has been raised from 4in. to 18in., and rises from this to 2ft 3in. at Paston-place groyne; but the consent of the Council has been obtained on the recommendation of your committee to raise the line to 3ft. above the chalk at Black Rock groyne (3) By the special request of the company, and on the recommendation of your committee, the Town Council has agreed that the concrete groyne at Black Rock shall be reduced from 7ft 6in to 3ft. solely for the accommodation of the company, to enable them to carry their line over the groyne, instead of constructing it in low water beyond the south end of the groyne (4) The car and the gantry on which it is carried, as it is now being constructed, is designed to carry 150 persons, and is estimated to weigh when finished upwards of 40 tons exclusive of the weight of the motors and driving gear, and of the weight of the passengers The total weight of the car and passengers will therefore probably be little short of 60 tons. (5) It is the intention of the company to abandon the use of accumulators and to drive the car by overhead wires carried on poles, a method known as the 'trolley system,' if the Council will give their assent to the proposal.

'The effects of these deviations from the original proposals are: (*a*) The lateral obstruction caused by the rails is doubled (*b*) The additional height of the rails is likely to be a source of danger to bathers and to boats when hidden from view by shallow water only. (*c*) The reduction of the height of the groyne at Black Rock as originally designed, although perhaps unimportant at the present time, may in future years seriously detract from its usefulness. (*d*) The increased weight of the car and its gantry will make it of such unwieldly and ponderous proportions that it will have a very different appearance to that of the little elegant toy car at first proposed to be used by the company, and of which a model was submitted to you. You will gather some idea of the proposed car if you will realise that it will be equal to the weight of five or six steam road-rollers or of an ordinary railway steam locomotive. (*e*) The proposed poles and overhead cables are likely to be an obstruction to the sailing craft at high water in rough weather and at night, owing to the poles and wires being invisible.

"With regard to the application of the company for your permission to erect within the borough 13 cast-iron poles 21ft. above the high-water line, with arms 4ft. long, to carry two lines of cable, or overhead wires, for the purpose of driving the car by what is known as the 'trolley system,' you instructed me to confer with the Corporation electrical engineer, and to call in other expert assistance if we required it, to consider whether the overhead wire system is the only one that can be adopted by the company. I beg to say that we have conferred together as directed, and your electrical engineer will send in his special report upon the subject of electric traction and its method of application; also as to the practicability of adopting a motive power other than electricity in order to avoid the use of overhead wires; therefore, I need not refer to that part of the subject.

"It is, however, within my province to report to you that in considering the subject from a broad or general engineering point of view, it was necessary that we should be supplied with further information respecting the scheme than that which had already been furnished. I therefore put the following questions in writing to the engineer of the company, but I have not yet received any written replies thereto: 1. What is the weight of the proposed car? 2. At what speed will it be driven? 3 What is the maximum horse-power required to drive it at any part of the line at the time of high tide? 4. On what data is this power estimated? 5. Send a detailed drawing of the car with the motors and trolley attached.

"The company's engineer and their electrical engineer, however, afterwards called together to see your electrical engineer and myself. They courteously offered to give us all the information they could, and we elicited from them at the interview that it was impossible for them to give us definite information in reply to the questions I had put to them, because, as the project is entirely a new departure in engineering, there is no known data or formula on which they could base their calculations. They assured us they had done their best to arrive at correct conclusions from their own experience, and such other information they possessed as could be applied; but at the same time, frankly confessed that their conclusions are, to a great extent, problematical, and that it is by experience only, after actual experiments made on the line, that more reliable information can be obtained or given.

"I quite believe this to be the true state of the case, and in view of the facts that the company have found it necessary to depart entirely from the first arrangements—that they have no reliable knowledge that the present proposals are workable—that they need knowledge which can be gained only by actual experiments—that your electrical engineer is of opinion that a motive power other than electricity may, in practice, be found better and cheaper than electricity—and having been informed by the company's engineers that neither the engines, dynamos poles, or wires have yet been ordered, I recommend your committee to endeavour to make an arrangement with the company for them to complete so much of their line as is outside the borough, and to make their experiments thereon. This line is two miles two furlongs two chains in length and, therefore, affords sufficient scope for the purpose. The line within the borough is only four furlongs eight chains in length and could be easily finished when the company had ascertained all the necessary particulars for working it successfully. These experiments and their results would afford your committee and the public an opportunity of forming a correct opinion as to whether the project is likely to be beneficial or prejudicial to the interests of Brighton."

The following is the report of the electrical engineer, Mr. ARTHUR WRIGHT:

"As requested by your committee, the borough surveyor and myself have carefully considered the new proposal of the Rottingdean Tramway Company for driving their car, and we agreed that it would be well for us to put our views in the form of two separate reports. I therefore beg to state that, judging as best I can from the unfortunately very scanty information obtainable from the engineers of the company as to the horse-power required by a car running under such novel and difficult conditions, I am of opinion that, as steam power is considered by the Corporation to be inadvisable, the only two remaining systems known to me by which there is any probability that such a line could be worked so as to be a mechanical and, possibly, a commercial success are:

"First, the ordinary trolley overhead wire electric traction system, as used in America, Bristol, and other places. This method, although it involves the use of overhead wires, has the advantage of great flexibility, in that an almost unlimited amount of power can be conveyed to the motors on the car. I consider this, under the circumstances, a great advantage, as it appears that only the most hazy ideas are obtainable as to the horse-power required to drive the tramcar through the water at anything like a reasonable speed. Other advantages are that the trolley system has been well tried and worked out, and is very cheap to instal.

"Second, the compressed gas-motor system, as about to be used at Blackpool and in use on the Continent, in which the necessary gas is carried in tubes under the car in a compressed state. This method has the great advantage over the first of being practically self-contained. Theoretically, it certainly ought to be cheaper in initial cost and maintenance than the other system, and considering the particular line of route I am not aware of any feature which would render it unsuitable for the tramway in question.

"In my opinion it is quite possible to drive the car by the ordinary electric accumulators, but I consider this system to be unsuitable by reason of its much greater expense, both initial and maintenance, than either of the other two systems, and I do not

Digitized by Google

consider that any combination of the electric accumulator and trolley systems could be satisfactorily worked in practice, as there are serious technical difficulties involved in the suggestion of working the car by accumulators while in the Brighton borough, and the trolley system when beyond it.

"Owing to the impossibility of ascertaining the horse power required to drive the car with its full complement of passengers, as neither the weight to be moved nor the amount of resistance due to wind and water or other friction appear to have been ascertained, and as no drawings have been submitted to me showing the proposed method of driving the wheels from the motors, I am quite unable to express a more definite opinion as to the practicability of the project beyond stating that I think it would be quite as possible to drive the car by compressed gas as by the overhead-wire trolley system, especially as I understand it is only intended to run one or at the most two cars."

The committee reported that they had also received communications from Sir Albert Sassoon and Colonel Wilson stating that they had no objection to the carrying out of the proposal, and from Mr. Mellor, on behalf of the Kemp Town Enclosure Committee, objecting to the erection of the poles.

The committee submitted the application of the company for the decision of the Council.

The following was forwarded to the town clerk, being the engineer's reply to the above reports:

17, Victoria-street, Westminster, S.W.
October 29, 1895.

The Chairman and Directors, Brighton and Rottingdean Seashore Electric Tramroad, Brighton:

Gentlemen,—In accordance with your instructions, I herewith beg to report on the subject-matter of the report of the Works Committee to the Town Council as follows: With reference to the gauge of the rails being altered from 24ft. to 18ft., and the number of lines of rails being increased from two to four, I beg to point that these alterations were sanctioned by the Corporation prior to the commencement of the work. The alteration in the level of the rails was rendered necessary by the height of the sand while the works were being carried out. The borough engineer stated to the Works Committee on their visit to our works that, judged from an engineer's point of view, he did not consider the rails had been laid one inch higher than was necessary to enable the line to be worked. I beg to enclose with this report two drawings to the same scale—A being the "model car" referred to by the borough engineer, and B the car as now being constructed.

I beg further to report that on the 15th inst. I received a letter from Mr. May asking for certain information as regards the car, and in order to save time I went to Brighton on the 15th inst, saw Mr. May and Mr. Wright early on the 16th inst, and gave them the following replies to their questions:

Question.—What is the weight of the proposed car? *Answer.*—The weight of the structure would be about 40 tons, and the weight of the electric machinery and people would bring it up to from 55 to 60 tons.

Question.—At what speed would it be driven? *Answer.*—We expected that the power we proposed putting on board would enable us to travel at an average speed of six miles per hour.

Question.—What is the maximum horse-power required to drive it at any part of the line at the time of high tide? *Answer.*—That we proposed putting two 30-h.p. motors on the car, which in our opinion would suffice.

Question.—On what data is this power estimated? *Answer.*—On the resistance (1) due to traction on the level, (2) due to the greatest incline, (3) due to the curve, (4) due to the wind, (5) due to the water, (6) due to the skin friction.

Copies of the drawing sanctioned by the Board of Trade were handed to them the same day. Pending the settlement of the question now before the Corporation, detail drawings of the electrical arrangement have not as yet been made, so I was unable to supply them with these, but at the same time explained that the trolley pole would be as sanctioned by the Board of Trade for the Bristol tramways. I did not understand from Mr. May that he wished me to repeat this information in writing. I cannot understand what experiments Mr. May desires should be made outside the borough boundary, and what object would be gained by the stoppage of the works within the same. In reference to this, I must point out to you that owing to the short time the work within the borough boundary is uncovered by the tide, we have only been able to complete 50 yards of the line between September 5 and October 21, so that any further stoppage of this portion of the works would render it impossible to complete the same within the time allowed by the Act of Parliament, which expires in July next.

The only point which now remains to be determined is, what speed will the car travel at with a certain amount of power? The great flexibility of the overhead wire system (as stated by Mr. Wright, the electrical engineer to the Corporation), in that an almost unlimited amount of power can be conveyed to the cars, coupled with the following facts: (*a*) the system has been well tried and worked; (*b*) the large range of power that can be obtained from electric motors; (*c*) that the motors can easily be changed, are the reasons which had led the advisers to the company to adopt this system, thereby ensuring that there will be sufficient power available to drive the car at a satisfactory speed.

With reference to Mr. Wright's (the electrical engineer to the Corporation) suggestion as to the adoption of gas-engines—this method of driving was carefully considered, prior to applying to the Corporation on May 14 for permission to temporarily use steam, and was abandoned for the following amongst other reasons: (1) No gas engines for traction purposes have been made approaching the power required. (2) The vibration in the compressed gas-motor cars to which Mr. Wright refers, although the motors are close to the ground, is considerable, therefore it is evident that if motors 10 times the power of these were placed on our high car, the vibration would be so excessive that passengers would not travel on it. (3) The objectionable smell and noise. (4) Serious mechanical difficulties in reversing and starting in the case of large powers, and where the inertia of our large car would have to be overcome. (5) The manufacturers, although willing to make an engine of sufficient power, would not, on account of the above-mentioned difficulties, undertake any liability as to the effective working of the arrangement.—Yours obediently,

R. St. Geo. Moore, Engineer to the Company.

The following notes, also, are the company's commentary upon the surveyor's report:

(2) This was an impossible condition imposed in the Corporation protection clauses owing to the undulating surface of the chalk and the shifting sand and was not in our original Bill at all. (*a*) The line as constructed does not cause any additional risk either to bathers or boats. (*b*) The following letters will show the site of the line was moved to allow the new groyne as originally designed to be constructed, and the line as now laid is 100ft. from the timber groyne, and that it was an amended proposal, of which we had no notification for 12 months afterwards, that caused all the difficulty. (*c*) The poles would be a distinct advantage as indicating the position of the line.

(1) The total width of the line is now only about 16ft. instead of 24ft., as originally intended.

(2) The words "or sand," which are in our Act, have been omitted after the word "chalk." The line was laid to conform to these conditions as far as possible, but the sand was withdrawn by gales when the surveyor measured the work; since then on two occasions the rails have been covered with sand. A photo showing the sand level with the rails will, if possible, be in the Council-chamber. (*a*) The rails being at one level the lateral obstruction is the same whether two, four, six, or any other number be laid. (*e*) With regard to this matter, the wires would be erected high enough to clear all small sailing craft. The submerged ends of the groynes, which project considerably further to sea than the line of rails, would cause all vessels to keep a course far outside them, whilst in stormy weather, when the whole shore is covered with breakers, a vessel getting within their influence would be wrecked any way, and the poles and wire would offer no obstruction to her coming ashore; and as at such times no current would be in the wire, no inconvenience could arise from this cause.

The following report of the Council's proceedings is from the *Sussex Daily News* of November 1:

Alderman Brigden moved that the report of the Works Committee on the application of the Brighton and Rottingdean Seashore Electric Tramway for leave to erect steel poles on the foreshore from Paston-place eastward be entered on the minutes. The committee, he pointed out, made no recommendation, but left the matter entirely in the hands of the Council. He wished the Council, however, to understand that the committee to a man had no hostility to the electric railway. It was a unique and novel venture, and they were all desirous of seeing it carried out satisfactorily.

The motion was put and carried.

Councillor E. A Dell: I move the adoption of the report.

The **Town Clerk**: There is no recommendation to adopt.

Councillor E. A. Dell: None whatever?

The **Town Clerk**: The committee have left it to the Council either to grant the request or not. It was now for any member of the Council to move a resolution.

Councillor E. A. Dell: I move that the report be acted upon. Well, I move that the request of the petitioners be granted.

Councillor Daniel: Which petitioners?

Councillor E. A. Dell: If you don't know, go to Rottingdean.

Councillor Booth, remarking that he had now entered on his anniversary of 25 years' service, said he would esteem it a great privilege if Councillor Dell would permit him to move a resolution.

Councillor Dell: Certainly; very pleased to see you returned to the Council without opposition.

Councillor Booth moved the following resolution: "That the application of the Brighton and Rottingdean Seashore Electric Tramway Company, dated September 23, for permission to erect 13 tubular steel poles, 80 yards apart, on the foreshore between Paston-place jetty and the borough boundary at Black Rock, for the purpose of carrying the electric trolley line, be, and is hereby, granted, provided that the company pay a rental of £1 per annum, and enter into a covenant to remove the poles on receiving three months' notice." He contended that the railway would be of the utmost benefit to the town, and would bring people to Brighton from the ends of the earth. (A **Member**: There are no ends of the earth.) Only a sixth of the whole line was within the jurisdiction of the Council, and he maintained that as the Board of Trade had more knowledge and greater responsibility in the matter than the Council, they would have been the first to raise objections if there had been any of a substantial character. As to the changes that had been made in the plans, he contended that they were essential in any invention. There was no comparison between the gas first introduced and the gas of the present time, and the same thing applied to the steam.

Digitized by Google

engine or the electric light. He urged that the Council should assist those who were making this courageous venture to secure its success, and warned members that if this resolution were rejected there would be no electric marine railway for two or three years.

Councillor Titcomb seconded the motion.

Alderman Abbey urged that the present scheme was a complete departure on the part of the railway company from the old scheme that was partially assented to by the Town Council. It embraced all the objectionable parts of the whole scheme, and now were added these poles and the overhead wires, the result of which would be that the inhabitants of Brighton would be deprived of a quarter of their foreshore. The foreshore of Brighton was nearly 4,000 yards in length, and it was proposed to destroy the use of it for about 1,000 yards. In granting this the Council should have some guarantee, some security in the way of a deposit, that in the event of the railway not being carried out the *débris* would not be left, probably for years, as a monument of their foolhardiness His amendment was that the application be granted conditionally on £1,000 being deposited as a security for the whole of the *débris* being cleared away if the railway did not answer, and that the whole matter be referred to the Works Committee to carry out.

Councillor Willett said he would second that.

After some little delay, **Alderman Abbey** put his amendment in this form: "That the motion be amended by adding the following words: Provided that the sum of £1,000 is deposited by the company with the Corporation by way of security for the removal of the tramway in the event of its being abandoned at any time hereafter, and that the details as to the application of such security be embodied in an agreement to be approved by the Works Committee."

Councillor Willett refused to second the amendment in this form, but **Councillor Wishart** said he would do so, as he thought this would be a sufficient safeguard of the interests of the town.

Councillor Daniel said they all knew Councillor Booth was very considerably interested in this matter. He was not speaking financially, and he might say that he was himself equal interested in it—for the good of the town. But Councillor Booth entirely ignored the fact that the surveyor had, at the request of the committee, reported on this application, and had practically told them point-blank that they would be doing a very foolish thing if they granted this application. Unless the Council got a more efficient control over the foreshore than was proposed, they would be making a great mistake in the interests of the town and in the boating and fishing interests.

Councillor George pointed out that the Council had already granted the company the power to raise their line 3ft. above the proposed groyne. That might be a very great obstacle to the boating interest, but it had been done.

Councillor Sutton said he supported the application almost entirely on the two reports furnished by the Council's own officials. The reduction in the height of the groyne was a matter already settled by the Council; and, moreover he thought it unfair to press for the company being bound down to full details when the surveyor admitted in his report that it was at present impossible to give them. But in the report of their own electrical engineer the Council would find all the justification necessary for granting the application. Mr. Wright said the trolley system was the best means to work the line to ensure financial success.

Councillor Titcomb urged that there was guarantee enough in Councillor Booth's motion, coupled with the fact that the promoters were putting their capital in the undertaking.

Councillor Blaker said he was going to give one of the most painful votes that it had been his unhappy pleasure ever to record Conscience spoke louder than his admiration of Mr. Volk, and as an east-end member he would vote against Councillor Booth If those 13 poles had been in the original proposal it would never have been listened to, and he considered the present scheme a violation of the rights of the people.

Councillor Dutton Briant said he found in an inspired article on the railway that the sand had shifted very much since the commencement of the undertaking, from which one might fear alteration in the future that would seriously affect the railway. Then the lines, he understood, were placed on concrete blocks "morticed into the rock." But the only rock was chalk, and with the vibration of a 60 ton car going over them was there any likelihood of the concrete blocks being able to hold on? He was anxious to see the railway a success, but these objections, in his mind, would have to be removed before he could support the proposal at all.

Councillor Halliwell said the company had shown by their action that they were anxious to meet the Corporation and carry out any additional suggestions possible. He contended that Mr. Wright's report was strongly in favour of the company's application, and urged the Council not to do an injustice to a private company. Let them carry on the farce no longer, but pass the resolution Councillor Booth had moved.

Alderman Moon said that Mr. Wright, instead of recommending the trolley system, really recommended the gas motor system He reminded the Council that in the first instance the promoters said the car would be run by means of accumulators. This, it turned out, was not impossible, but would probably prevent the railway being a commercial success This was not the fault of the Council, nor of the Works Committee They naturally supposed that when gentlemen commenced an undertaking they counted the cost, and did not begin until they knew they could finish. It seemed to have dawned on the promoters in some way that the car, instead of a light thing, would have to be 40 tons in weight, or with passengers and motors 60 tons—about five times the weight of a road-roller, or about the weight of a locomotive. That was not the fault of the Council, nor the Works Committee. Then the company raised their rails from 14in. to 18in. without any notice to the Corporation, and now they asked for leave to erect thirteen steel pillars of a considerable height with brackets to carry a cable about ½in. in diameter, probably with suspending cables. It was not only a question of the danger to boating and bathing, but of how far this was going to interfere with the beautiful view. Alderman Lowther had suggested to him that it might be practicable to extend the present electrical line to the eastern boundary, so that the steel poles would not be necessary.

Councillor Titcomb: That belongs to another company.

Alderman Moon: That is not an insuperable difficulty. We are dealing with men of genius and resource.

Councillor Weston said he had always been an opponent of the electrical line on the front, because it took the beach away from the people. He thought the rent fixed should be at least £100.

Alderman Reeves suggested for the consideration of the Council whether, at a private meeting of the Council in about a fortnight's time, with the electrical engineer, the surveyor, and the engineer to the company present, they would not be able to arrive at a better understanding on the matter, and a more just conclusion than at present. Alderman Reeves afterwards explained, in reply to Councillor McClean, that the meeting need not necessarily be held *in camera* He meant a meeting of the Council held under the rules for committees.

After some hesitation, **Councillor Booth** accepted this proposition, and amendment and resolution were withdrawn by leave of the Council.

On the motion of **Alderman Reeves**, it was then formally decided that the debate be adjourned to a convenient time, about a fortnight after the election of the new Council, that the company be invited to send their engineer, and that the borough surveyor and electrical engineer attend.

LEGAL INTELLIGENCE.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY v. EBBSMITH.

On Monday, in the Court of Appeal, consisting of the Master of the Rolls and Lords Justices Lopes and Kay, Sir F. Lockwood, Q.C (with whom was Mr. Scrutton) appealed from an order of Mr. Justice Hawkins refusing the plaintiffs leave to inspect the books and take copies of the banking accounts of the defendant (Mr. Ebbsmith) and of the Dickinson Tramway Appliance Company at the branch office of the Metropolitan Bank of England and Wales, and to inspect as well the books of the Staffordshire Joint-Stock Bank and their successors for the years 1885 to 1894. The plaintiffs were bringing an action against the defendant Joseph Ebbsmith and William James Carruthers Wain for the rescission of certain contracts for the purchase of the patents and certain land at Wednesbury, and the return of the money paid for the same, with interest at the rate of 5 per cent.

Lord Justice Kay said it was a strong step to ask for leave to inspect the banking account of the Dickinson Company, as well as the banking account of Mr. Ebbsmith, the defendant in this action.

Sir F. Lockwood said that Ebbsmith and the Dickinson Tramway Appliance Company were one and the same. The plaintiff company was brought into existence in 1889. It took over the property and rights of the South Staffordshire and Birmingham and District Steam Tramways Company, of which the defendant was a promoter, and was from March, 1887, until April. 1889, local solicitor of that company, and from the latter date he was its parliamentary solicitor. Both defendants are promoters of the plaintiffs, and as such they are in a fiduciary position to the limited company and the plaintiffs. They had, as the plaintiffs alleged, made "secret profits."

The **Master of the Rolls**: And you want to inspect the bank books to get evidence against them?

Sir F. Lockwood: Yes; we say that the defendant Ebbsmith sold us patents which were worthless, and land that was unnecessary at Wednesbury, and if inspection of the bank books be granted we can show that Ebbsmith—whose name was formerly Smith—was in fact the Dickinson Appliance Company, and that the money we paid to that company went to his account. He owned 1,500 out of the 1,507 shares in the company, the other shares being held by his clerks

The **Master of the Rolls**: It is an unusual request to make.

Sir F. Lockwood said that the office of the Dickinson Appliance Company was the office of Ebbsmith, who had been solicitor to the South Staffordshire and Birmingham and District Steam Tramways Company. We produced affidavits before Master Butler when he made the order for the inspection of the bankers' books at Wednesbury. The cashier of the Dickinson Appliance Company was Mr. Ebbsmith's own clerk, and, in a word, it seemed that he was the Dickinson Company himself.

The **Master of the Rolls**: We have had a good deal of experience during the last six months in this little game.

Sir F. Lockwood: Unfortunately it is not a little game; it is a big game. He gets a patent for next to nothing and sells it to the Dickinson Company for £5,000.

Lord Justice Kay said that Sir F. Lockwood had not given any proof of the statements that he had made—that Ebbsmith was the Dickinson Company.

Sir F. Lockwood said that Ebbsmith sold three acres of land for £1,000 to the Dickinson Company, and the plaintiffs alleged that this land was not necessary for the purposes of their under-

Digitized by Google

taking. In fact, the plaintiffs alleged that the Dickinson Company was Ebbsmith's own company.

Mr. Loehnis said he was there to represent the Dickinson Company, which was quite apart from Mr. Ebbsmith.

Mr. Bower said he appeared for Mr. Ebbsmith alone, and he was there to oppose the application.

The **Master of the Rolls** said he thought Sir F. Lockwood ought to be allowed to support his statements by affidavits.

Mr. Bower asked for the dismissal of the appeal, as against Mr. Ebbsmith, with costs.

The **Master of the Rolls**: We refuse to do that. We postpone this appeal until next week, and all other questions with regard to it.

Mr. Bower: I think we ought to have our costs of the postponement.

The **Master of the Rolls**: The question of costs, also, is postponed.

ROTTINGDEAN ELECTRIC LIGHT WORKS.

In the Chancery Division of the High Court of Justice on November 1, before Mr. Justice Kekewich, **Mr. Renshaw, Q.C.**, said that he had a motion in an action in which Sir E Burne-Jones, who was the plaintiff, moved for an injunction to restrain the defendants—the New and Mayne Company—from working electrical machinery at Rottingdean in such a manner as to cause a nuisance to the plaintiff by noise, vibration, and smoke. The defendants had submitted to a perpetual injunction and to pay the costs. Operation of the injunction was ordered to be suspended so as to enable the company to carry out alterations to abate the nuisances complained of.

COMPANIES' MEETINGS AND REPORTS.

ELMORE'S COPPER DEPOSITING COMPANY, LIMITED.

The annual meeting of this Company was held at the Great Northern Hotel, Leeds, on November 1, Mr. John North (chairman) presiding.

The **Chairman**, in moving the adoption of the report, which appeared in our last issue, observed that the directors had been in office rather less than 12 months. Although they had not had at their disposal any other resources than those possessed by their predecessors, and notwithstanding that during the past year there had been a drop in the average price of their finished manufactures of over £12 per ton, they had been able to wipe out the old sources of loss which were so serious in the two preceding years, and to effect an actual net profit of £480. 6s. 4d.—a profit which was even rather better than it looked upon paper. They had also had, as previously, to contend with determined competition, and the year had had to bear the burden of one or two low-priced contracts, which had not been executed at the time they took office. Explaining this improvement, he said that, in the first place, there had been a much larger turnover in the factory without any corresponding increase in the expenses, and next they had effected considerable economies, and further, the Messrs. Elmore had, if possible, exceeded their former efforts in striving to lift the Company out of its former difficulties. If they had been working all this year to their full capacity they should have presented a very different account. As to the profit, he entered into a number of financial details, and said that there was really a net profit of £1,236 on the proper basis of the Company's manufacturing operations. They had reached a point when it was practically impossible to do better than they had during the last six months unless the Company was furnished with adequate capital. The Company had no difficulty in securing very remunerative orders, and they expected to be appointed on the list of contractors approved by the Admiralty, which would enormously increase the amount of business offered to them. They had already supplied tubes and cylinders to foreign navies, though they had not yet been directly appointed contractors to the British Navy. The comments passed upon the copper condenser cylinders made for Russian boats built by Mr. Yarrow by competent engineers were very gratifying, and it was well to remember that these large cylinders could only be produced by the Company's process. With regard to the method of raising further capital, it was proposed to extend the Company's borrowing powers, as such a step would give them every power and facility that could be afforded by an increase in the share capital of the Company, while it had the advantage of saving the expense of increasing the share capital, and possessed other advantages. They already had some substantial offers of assistance in the debenture issue, but in the first place the offer would be made to the shareholders, and the directors hoped they would respond now that the Company had been brought through its difficulties and established upon a paying basis. With regard to the proposed reduction in the ordinary share capital, he thought it must be evident to all of them that that step was necessary, and that at the same time it inflicted no injury or loss upon anyone. The Company's profits would be exactly the same whether the capital was reduced or not, and the dividend upon the reduced share would, of course, be double the rate of the dividend paid upon the full amount of the share, so that the market price of the reduced share must respond to the dividend in either case. The chief advantage of the reduction would be that it wiped out the old loss and enabled them to divide at once any profits as they were made. It might be well, perhaps, if he explained the meaning of the resolution to be submitted to the preference shareholders. The terms upon which the preference shares were created were that they received a preferential 10 per cent. dividend, and then the ordinaries took 10 per cent., and the balance, if any, was divided *pari passu* amongst the preference and ordinary shares together. In practice, this meant—provided the profits were sufficiently large—that the preference and ordinary shareholders would always receive exactly the same dividend upon their shares, but this equality of dividend would at once be upset if the ordinary share capital was reduced by 50 per cent., and unless the preference shareholders passed the resolution to which he referred the ordinary shareholders in future would only receive half as much as they would have received if the capital had not been reduced. They, of course, were not asking the preference shareholders to give up anything whatever of their rights; they were only asking that they would not take more than they were now entitled to. In future the practice would be to give the preference shares a preferential 10 per cent., and then 20 per cent. to the ordinary shareholders on the reduced capital, and the balance (if any) would be divided in the proportion of about 91 per cent. to the ordinaries and 9 per cent. to the preference.

Several shareholders, while recognising the good work accomplished by the present Board, offered a mild criticism to some of the features of the report, and one of the speakers concluded with an amendment in favour of a committee of inspection. The amendment, however, only found four supporters, and the original resolution was adopted, with the suggestion, accepted by the chairman, that the directors be authorised to write off £11,012 standing to the credit, and the reducing the assets to that extent.

Mr. John Marshall was re-elected on the directorate, and Messrs. H W. and J. Blackburn were reappointed accountants.

The **Chairman**: Mr. Marshall and your directors urged upon the shareholders to assist them in raising the required additional capital. If they could raise £30,000 it would mean a largely increased business.

Special meetings were afterwards held, and resolutions adopted in favour of raising the additional capital.

WOODHOUSE AND RAWSON UNITED.

A meeting of the debenture-holders of this Company was held on Tuesday last at Cannon-street Hotel, E.C., Mr. C. J. Stewart (the official receiver) presiding.

The **Chairman** said that the meeting had been called in consequence of an order of the Court. At a meeting on June 13 last it was decided by a majority of those present that the debenture-holders were averse to the funds realised in the debenture action being appropriated for the purpose of taking proceedings against the directors, auditors, and officers of the Company under Section 10 of the Act Following on the public examination, a case was prepared by the solicitors who were acting for the official receiver and liquidator, which was submitted to the solicitors representing the receiver, and the case was approved by them, and was submitted to counsel, who gave it as his opinion that proceedings would be successful with respect to dividends paid by the Company during certain years. The matter came before Mr. Justice Vaughan Williams, who had directed that meetings of the debenture-holders should be held for the purpose of obtaining the votes of the debenture holders for or against taking proceedings against the directors and auditors. If the majority, who were averse to taking proceedings, were to abandon their claim, it would leave it open for those creditors standing after them to find the money for proceeding, and take the profit of whatever might be recovered. The votes, therefore, would be taken separately of the 5½ and 6 per cent. debenture-holders as to taking proceedings or not, and in the event of not taking proceedings of abandoning or giving up their claim.

Some conversation took place as to the exact effect of the voting papers the debenture-holders were asked to sign and hand in, and the **Chairman** stated that would report the result to the Court.

THE VICTORIA ELECTRIC RAILWAY AND LIGHTING COMPANY, LIMITED.

A meeting of the debenture-holders of this Company was held on Wednesday at 8, Austin-friars, Mr. R. M. Horne-Payne presiding.

The **Chairman**, after stating that £1,000 of bonds had that morning been drawn for redemption at 105 per cent., remarked that immediately after the results of last year's working became known the trustees, in accordance with the powers vested in them, paid away £43,000 in respect of liabilities. It afterwards came to the knowledge of the trustees that there existed further liabilities of between £8,000 and £10,000. As these had not been disclosed in the directors' schedule they declined to recognise them, and this action on their part brought the Company to a deadlock. One of the creditors then applied to the Court for the appointment of a receiver, and his application was granted, with the distinct understanding that every penny of earnings should be held in trust for their bonds, and that all mortgages and encumbrances should be protected. The Court at the same time admitted that the debenture-holders had the right, if they desired to exercise it, to enter into possession of the property. In these circumstances, it became the duty of the trustees to consider how they could best secure the interests of the debenture-holders, and, as a result, preliminary negotiations had been entered into with the Consolidated Railway of British Columbia to work the line, and to guarantee their bonds in

Digitized by Google

consideration of receiving the surplus profits of the Victoria Company. The Consolidated Company's bonds bore interest at the rate of 4½ per cent., and they would consequently only guarantee the bonds of the Victoria Company up to the same amount. It was proposed in order to make the interest up to 5 per cent., that the holders of Victoria bonds should receive for each £100 one-quarter of 100dol. fully-paid ordinary share of the Consolidated Company. If some such arrangement was come to the debenture-holders would avoid the trouble and risk of themselves working the line, and their security would be, if anything, rather better than before.

On the motion of **Mr. Sperling**, seconded by **Mr. Sidney White**, the trustees and directors were authorised to carry out and complete the negotiations on these lines, and it was stated that the chairman would at once go out to Canada with that object. It also appeared that, in spite of the receivership, the receipts of the railway during the last year showed an increase of more than 10 per cent.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY, LIMITED.

A special meeting of the shareholders of this Company was recently held at the Harlech Castle, Oswestry, when there were present Messrs. A. Wynne Corrie (chairman), E. Bremner Smith (managing director), and Robert Lloyd and George Perks (directors).

The **Chairman** said he considered the report the directors had to make was very satisfactory. They were selling between two-thirds and three-fourths of one unit, but the Board of Trade required them to raise £500 of capital, and they meant to send round to the present shareholders so as to give them the first chance of taking more shares, and after they had received replies from them they would invite the public to take shares. It seemed to him that those who had already taken shares might like to increase their number, and that as they had backed up the Company originally they might feel that they should be given the first chance now the Company promised to be flourishing.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The report of this Company for the June half-year, to be presented at the thirtieth ordinary general meeting in London on Thursday next, states that the total earnings amounted to £84,937, as against £77,603, an increase of £7,334 compared with the corresponding period of 1894. The working expenses came to £37,891, as against £37,953, a decrease of £62. Including £2,846, the amount brought forward, the balance to the credit of the revenue account is £49,891, from which has to be deducted £11,223 for debenture interest, £7,877 for the debenture redemption fund, £1,730 for income tax, and £5,000 placed to the reserve fund. The directors now recommend the payment of a dividend at the rate of £2. 10s. per cent. per annum, as against £2 per cent. per annum for the corresponding period, carrying forward £5,803. This dividend will be payable 3s. 9d. per share to the ordinary and 3s. 9d. per share to the preferred ordinary shares The position of affairs between the Government of Brazil and the Company as to the acquisition of the cables remains the same as at the date of the last general meeting. The Government, however, are taking authority to continue the authorisation for the purchase of the Company's system. The shareholders are aware that the Amazon Telegraph Company, Limited, has recently been formed for the purpose of laying a system of cables up the River Amazon and connecting many important places on that river with Para, the northern terminus of this Company's system. The directors anticipate that when this line is opened, in or before March next, it will prove a valuable feeder to this Company. The directors have to notify that the conversion of ordinary shares into preferred ordinary and deferred ordinary shares will be suspended on and after January 1 until further notice.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The report of this Company for the half-year ended June 30 states that the amount to the credit of revenue is £39,849, against £40,598 for the corresponding half-year, and the expenses have been £21,848, against £24,488, leaving a balance of £18,001, which, with £710 brought forward, makes a total of £18,711. A dividend on the ordinary shares of 1s. 3d. per share, tax free, is announced, leaving a balance of £1,421 to be carried forward.

THE ALUMINIUM COMPANY.

The report of the directors for the 12 months ended June 30 states that their forecast regarding the value of the new patents belonging to the Company has been realised, and that the general business of the Company at Oldbury continues satisfactory. The accounts show a gross profit of £16,901 for the financial year. After providing for debenture interest, amounting to £7,497, and other fixed charges, there remains a balance of £3,901, which, with the sum of £1,475 brought forward from last year, makes the sum of £5,376 available for distribution. Out of this the directors recommend the payment of a dividend of 5 per cent. for the year on the "A" shares, which will absorb £3,000, leaving a balance of £2,376 to be carried forward. The shareholders have been informed of the agreement entered into in January last with the Mathieson Alkali Company, of America, for the sale of the electrolytic alkali patents for the United States, and the directors have to report that the plant has been completed, and is now being put into operation. The Company are to receive upon the satisfactory running of the plant the sum of £65,000, payable as to £30,000 in cash and £35 000 in shares, besides substantial royalties calculated on the output, with a minimum sum guaranteed during the life of the patents. In October last an agreement was concluded with Messrs. Solvay et Cie., who are the owners of the Kellner alkali patents, for a combination of both the Castner and Kellner patents, for the mutual advantage of the Aluminium Company and Messrs. Solvay et Cie. The Aluminium Company, under this arrangement, obtained the sole right to work the combined patents in England and the Colonies, and Messrs. Solvay et Cie. the sole right to work the same patents on the Continent. The agreement also makes provision that both companies shall work in friendly alliance for at least 12 years, and the Aluminium Company receive a sum of £5,000 as an extra consideration for such agreement. This arrangement enabled the directors to sell the Castner patents with the benefits of the agreement with Messrs. Solvay et Cie. (other than the right to receive the said sum of £5,000) to the Castner-Kellner Alkali Company, Limited, for the sum of £125,000, payable as to £25,000 in cash and as to £100,000 in shares. Such intimation was given to the shareholders at the last meeting as to another important chemical process invented by Mr. Castner. So successful has this last process proved to be, that an arrangement has been concluded between this Company and one of the largest and most influential firms in Germany for the sale of the American patents, together with certain other manufacturing privileges. This Company will receive the sum of £10.000 (£5,000 of which has already been paid) and 30 per cent. of the share capital of the American company now being formed, the capital of which has been guaranteed by the German firm. This leaves the Continental and British patents still to be disposed of, and as negotiations are pending for their sale it is deemed advisable to make no further announcement. The directors consider that any depreciation on the patents and on the works at Oldbury is more than covered by the developments in respect of patents which stand on the books of the Company at comparatively nominal figures. It is decided to pay off the £12,000 10 per cent. "B" debentures which fall due on January 1, 1896. The directors are also making arrangements for reducing the present £6 per cent. debenture debt by paying off the present issue, and, if necessary, raising a much smaller loan at a lower rate of interest.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

New Windsor.—The Windsor Corporation invite proposals by January 1, 1896, for taking over and working their electric lighting order. For particulars see advertisement columns.

Saarbruck.—Tenders are invited by November 15 for the supply of 1,500 telegraph posts. Conditions, etc., for one mark from Die Eisenbahn-Telegrapheninspection, Saarbrücken, Germany.

Lisbon.—Tenders will be received up to November 13 for the supply of various spare electrical machinery, for the Portuguese Royal Railway Company. Conditions, etc., at Paris, rue de Châteaudun, 28

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Fermoy.—The Town Commissioners of Fermoy, co. Cork, invite tenders and schemes from electrical, manufacturing, and contracting companies for the lighting of the town of Fermoy (public and private) by electricity. For particulars see advertisement columns.

Kassel.—The Fulda Canalisation Direction invite tenders for the supply of six automatic water-level indicators, with electric alarms. Pneumatic apparatus preferred. Particulars from and tenders to Das Hauptbauamt der Fuldakanalisirung in Kassel, Lutherstrasse 5, II.

Punta Arenas (Chili).—Tenders will be received until December 5 for the manufacture and laying of a submarine telegraph cable from Puerto Montt to Punta Arenas. The conditions and specifications may be consulted in the Chilian Legation, Member's-mansions, 36, Victoria-street, S.W.

Cambridge.—Tenders are wanted for the supply of 1,000 tons of steam coal, for the Cambridge Electric Supply Company, Limited. Full particulars and conditions, with form of tender, may be obtained on application at the company's offices. Mr. John H. Barker, secretary, Thompson's-lane, Cambridge.

Madrid.—The Director of Public Works invites tenders by November 15 for the concession of the construction and working of a tramway from Madrid to Colmenar Viejo, with branches to Chamartin and Rosa. Security, 12,505 pesetas. Particulars at the Direccion General de Obras Publicas (Ministerio de Fomento), Madrid.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each

Digitized by Google

of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Blackburn.—The Corporation of Blackburn are prepared to receive tenders by November 30 for the following: Section (B)—steam alternators and motor alternator; Section (C)—switchboard and engine-room connections; Section (D)—street transformer-chambers, transformers, etc. For particulars see advertisement columns.

Huddersfield—Tenders are invited for the works required in erection of a mill, and include an engine-house, boiler-house, chimney, dynamo house, etc. The specifications may be obtained of Messrs. John Kirk and Sons, architects, Huddersfield and Dewsbury, from 14th to 28th inst., on which latter day sealed tenders are to be sent in to them.

Paris.—The Director Générale des Postes et des Télégraphes, rue de Grenelle 103, Paris, invites tenders by November 21 for the supply of 6,000 iron cross-pieces with galvanised accessories, 29,000 cross-pieces with accessories, 134,000 consoles, and 400,000 galvanised iron screws (eight lots). Requests for admission to the adjudication before November 11.

Derby.—The Corporation desire tenders for the wiring, fittings, etc., for the completed portion of the Derby Municipal Technical College, Green-hill, Derby. Specification and form of tender, containing plans, schedule of rooms, etc, may be had on deposit of £1 1s., which will be returned on receipt of a bona fide tender, from Mr. J. E. Stewart, engineer, Electric Lighting Station, Derby, on and after 4th inst. Tenders, endorsed "Wiring, etc, of College," to be sent to Mr. H. F. Gadsby, town clerk, Town Hall, Derby, by 12 noon on 12th inst.

Warrington.—The Cheshire Lines Committee, among other stores to be supplied in 1896, desire tenders for telegraph materials, instruments, and wire. Patterns can be seen and specifications, with forms of tender, obtained upon application to Mr. Saxon Barton, storekeeper, Cheshire Lines, Warrington, and intending contractors are requested to particularise the stores for which they wish to tender. Sealed tenders, endorsed "Tenders for ——," to be in the hands of Mr. Glegge Thomas, secretary, Central Station, Liverpool, addressed Cheshire Lines Stores Department, Warrington, by 10 a.m. on 30th inst.

London, S.E.—The Metropolitan Asylums Board desire tenders for the execution of wiring and other work in connection with the electric light installation at the Brook Hospital and Ambulance Station, Shooter's Hill, S E. Copies of the specification, form of tender, conditions of contract, and of the drawings which have been prepared by Prof. Kennedy, LL D, F R.S., 14, Old Queen-street, Westminster, can be obtained of Mr. T. Duncombe Mann, clerk, Norfolk House, Norfolk-street, Strand, W.C., on and after 4th inst., upon depositing gold or Bank of England notes to the value of £25, which will be returned only to those who send in a bona fide tender, and who return the drawings, specification, and conditions of contract Tenders which will only be received on the lithographed form supplied by the Board, must be sealed and endorsed "Tender for Wiring, etc.," Electric Light, Brook Hospital," and must be delivered at the offices of the Board by 11 a.m. on 18th inst. Unless the tender be accompanied by the specification, conditions of contract, and the drawings, it will not be considered.

RESULTS OF TENDERS.

Southwark (London).—The St. Saviour's Guardians have accepted the tender of Messrs. Morris and Son, at £59. 10s., for an installation of the electric light in the Board-room and offices.

Aberdeen.—For the electric light wiring of the Aberdeen Public Library, for the Library Committee (Mr. Alfred S. Blackman, city electrical engineer), the tender of Messrs. Shirras, Laing, and Co., Schoolhill, Aberdeen, has been accepted.

Bradford.—The Gas and Electricity Supply Committee will ask the Town Council to-morrow (Saturday) to ratify a resolution accepting the tender of Messrs. Holdsworth and Sons for the supply of a boiler for the chemical works for the sum of £273.

Dewsbury.—The tender of Mr. G. A. Steinthal, of 41, Piccadilly, Bradford, has been accepted for wiring the public baths and library for the Corporation. The following is a list of the tenders received:

G. A. Steinthal, Bradford	£284	0	0
A. R. Turner, Dewsbury	295	0	0
J. A. Edmondson, Leeds	307	1	6
Maunsell, Mercier, and Co., Manchester	346	14	0
A. Sykes, Huddersfield	392	0	0
Lomax, Kendal, and Co., Manchester	405	0	0
Paterson and Cooper, London	424	15	0
A. Hirst and Son, Dewsbury	424	16	0
Fowler, Lancaster, and Co., Birmingham	482	0	0
Northern Counties Electrical Construction Company, Manchester	641	0	0
Howe Electrical Engineering Company, Liverpool	895	0	0

The inclusive cost of the work was estimated by Mr. John B. Mitchell, the borough electrical engineer, to be £393.

City and South London Railway.—The returns for the week ended November 3 were £971, compared with £939 for the corresponding period of 1894, being an increase of £32. The total receipts for the half-year 1895 are £15,649, compared with £15,750 for the corresponding period of 1894, being a decrease of £101.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of October the receipts were £30,400.

British Electrical Manufacturing and Engineering Company, Limited.—The subscription list opens to-morrow, at 10, and closes at 4 p m. on the same day.

Huyton-with-Roby (Lancs.).—The Urban District Council have resolved to oppose any application for a provisional order for the adoption of the electric light.

Metropolitan Electric Supply Company, Limited.—The directors announce the payment of an interim dividend of 3s. per share for the half-year ending June 30.

Southampton—It is stated that the dock authorities, hearing that the Mersey Dock Board have decided to light their stages by electricity, have resolved to similarly light their quays.

Reigate.—Mr. F. H. Medhurst, of 13, Victoria-street, S.W., has been appointed the Corporation electrical engineer to design and carry out a scheme to light the borough with electricity.

Herne Bay.—A town's meeting has passed a resolution in favour of a deep-sea pier being constructed by the Urban District Council or otherwise. An electric tramway is included in the scheme.

Wakefield.—The Wakefield Tradesmen's Association have passed a resolution expressing satisfaction at the action of the Corporation in taking steps to provide the city with electric light.

Harrow.—The Urban District Council have decided that the chairman (Dr. Williams) and Mr. Hawkins should attend the forthcoming Board of Trade conference on electric lighting regulations

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended November 3 amounted to £1,046, as compared with £884 in the corresponding week of last year, being an increase of £162.

Brompton (London).—The committee of the Cancer Hospital, Brompton, have decided to introduce the electric light throughout the hospital premises, and have instructed Mr. Morgan Williams, C.E., to prepare specifications for the work.

Denbigh—The County Council have accepted an invitation from the Merionethshire County Council to appoint a committee with Merioneth and Carnarvon to examine and report on the possibility of constructing a light railway on the Holyhead road from Corwen to Bettwsycoed.

Eastbourne.—The town clerk has received a letter from the secretary to the General Post Office stating that the Postmaster-General had given instructions for the extension of the telegraph to the Upper-avenue Post Office, and that it was to be carried out as soon as possible.

Chelsea Electricity Supply Company, Limited.—Application has been made to the Stock Exchange Committee to allow the following securities to be quoted in the official list: 6,000 6 per cent. preference shares, Nos. 14,001 to 20,000, and a further issue of 3,723 ordinary shares.

English Automobile Horseless Carriage Syndicate, Limited. This Company has been registered with a capital of £5,000 in £1 shares. Object: to construct and deal in locomotives, carriages, etc., wholly or partly propelled by steam, electricity, compressed air, or other mechanical power.

Manchester.—The Corporation's Bill, to be introduced next session, includes powers for the Corporation to run carriages and work tramways within the city, and to provide such plant as may be requisite, and authorises the use of electricity or other mechanical power as a mode of traction.

Bexhill (Sussex).—The report of the clerk to the Urban Council, Mr. F. A. Langham, on the application of Viscount Cantelupe and another gentleman for the consent of the Council to apply for a license for introducing the Electric Lighting Act in Bexhill, has been referred to the Lighting Committee.

Eccles (Manchester).—Alderman Kendall, in moving the adoption of the Town Hall, Tramways, and Electric Lighting Committee's report, said that it would be for the members of the new Council to say whether the electric lighting scheme for the borough should be proceeded with. The report was adopted.

Automotive Syndicate, Limited.—This Company has been registered with a capital of £5,000 in £1 shares. Object: to carry on business as manufacturers of electric, steam, gas, oil, or other motors; as mechanical engineers, metalworkers, steel converters, etc. The directors are E. H. Preen, M. H. Smith, and G. L. Lyons.

Electric Traction in Switzerland.—A syndicate, having its seat at Zurich, has applied to the local and federal authorities for the concessions of several electric metre-gauge road railways, to be constructed in the cantons of Zurich, Argovie, and Zug, the plans and designs having been prepared by Dr. Du Riche Preller, M.I.E.E.

Fort William (N.B.).—At a meeting of the Provisional Committee of the Fort William Electric Lighting Company it was intimated that all agreements had now been adjusted. It is understood that the company will be registered within the next few days, and that operations will be commenced immediately thereafter.

Improved Electric Glow-Lamp Syndicate, Limited.—This Company has been registered with a capital of £5,000 in £1 shares. Object: to enter into an agreement, made October 25, with T. H. Jones for the acquisition of certain patents relating to improve-

Digitized by Google

ments in globes for electric glow lamps, and to develop and turn to account the same.

Electric Tramways in South Africa.—The Port Elizabeth electric tramways have been sold to Mr. Henry Butters, of Cape Town, who undertakes, as one of the conditions of the sale, to introduce electric traction on most, if not all, of the lines. Cape Town already has a system of electric lines under way, and the demand for electric motors in South Africa promises well.

Chatham.—The local electric light company having written to the Town Council saying they had orders to place arc lamps on posts upon the pavement in the High-street from private customers, and asking what further notice, beyond three days, the Corporation would require, it was recommended that the Corporation do not sanction the erection of such lamps on the footpaths.

Caledonian Railway Company and the Electric Light.—The Caledonian Railway Company, it is understood, owing to complaints from the inhabitants in the vicinity of their Morrison-street Depôt, Edinburgh, regarding the spray from the Lucigen lights, have decided to remove them and substitute the electric light. The Company at the same time have decided to light their goods yard at Lothian-road with electricity.

Bournemouth.—The Town Council have received a letter from the Board of Trade inviting the Corporation to appoint a representative or representatives to attend a conference, to be held on November 19, with reference to draft regulations for the safety of the public under the Electric Lighting Acts It was resolved to appoint the chairman of the Lighting Committee, the town clerk, and borough surveyor to attend the conference.

Chagford (Devon).—A parish meeting has been called by the Council to vote the amount required for lighting the streets. The Council have accepted the tender of Messrs. Willey for lighting the streets by gas instead of the electric light, and, as a protest against the action of the Parish Council, it was moved, "That this parish meeting refuses to vote any sum for lighting the streets until the Parish Council bring forward a better scheme for lighting."

Bath.—Alderman Sturges has referred to the notice which had been received from the Electric Lighting Company. applying for the Authority's consent to their application for a provisional order. He said he would merely move that the application of the company be nct assented to, remarking that it would be ridiculous for them to do otherwise, seeing that they had already made up their minds to apply for the provisional order themselves. The motion was carried.

East Grinstead (Sussex).—The Urban Council have received a further letter from Messrs. Lucas and Pyke explaining their proposals for the electric lighting of the town, the effect of the letter being that they could supply four times the present light at the same expense. No objection was made to the principle of the matter, and the recommendation made on the subject by the committee was interpreted to mean that, providing the light was installed, the Council should undertake to use it

Llandudno.—The shareholders in the Great Orme's Head Marine Drive have resolved to sell the company's rights in the drive round the Great Orme to the Edison-Swan Electric Supply Company, of Manchester, at a price agreed upon, for the purpose of laying an electric tram round the Orme on the road hitherto used as a carriage drive. It is stated that the company intend applying to the District Council for permission to make a connecting line along Gloddaeth street and North-parade past the Happy Valley, so as to make the circular tour complete.

Whitechapel, E.—The District Board have appointed the Rev. J. H. Scott and Messrs. Brady and Chillingworth as delegates to attend the meeting called by the Board of Trade on the 19th inst., when it is proposed to discuss the various observations and suggestions which have been received by the Board of Trade with reference to the revised draft regulations which have been prepared by that Board under the Electric Lighting Acts, 1882 and 1888, for securing the safety of the public, and for ensuring a proper and efficient supply of electrical energy.

Beckenham (Kent).—The Urban District Council have received a letter from the Board of Trade on the subject of electric lighting, stating that it was proposed to discuss the matter at a meeting to be held shortly, and if the Council desired to be represented they should send the names of those who would attend on their behalf The Clerk said the Council had already a provisional order for electric lighting, but had taken no steps in the matter, and he suggested that some member or officer of the Council should attend the meeting. It was agreed that Mr. C. E Baker and the clerk should again represent the Council at the meeting in question

Fulham (London).—The Vestry have rescinded their decision to light a street in the district with incandescent gas burners on the ground that they were now going fully into the question of electric lighting. The Special Committee on Electric Lighting have reported that of the three electrical engineers who were invited to attend their meeting two attended. but as only six members of the committee were present it was decided to ask them to attend again. The Vestry have decided to hold a special meeting on the 27th inst. to consider the question of applying without delay to the Board of Trade for a provisional order enabling the Vestry to undertake the public and private electric lighting of the parish.

Norwich.—On the order to pay to the National Telephone Company, Limited, the sum of £10 for rent of the telephone wires and instruments for the workhouse and Guardians' office due November 1, a Guardian said that he considered that the rental was most extravagant, and moved that the payment be not made, but that the company be asked to reconsider the rental charged for all the wire used by the Guardians. There was a good deal of competition, and it was expected that the Government would give a new company powers over the lines of the National Telephone Company, so that telephoning would soon be as cheap as talking! The Board eventually decided to leave the matter over until some enquiries have been made.

Clerkenwell.—The Works Committee of the Vestry have reported that the County of London Electric Lighting Company, Limited, applied for permission to drain their transformer chambers into the nearest gullies, but that they (the committee) had refused the application, and informed the company that the drains must be carried into the sewers in the ordinary way. In reply to a question, the surveyor said that the gullies sometimes got choked up, and to his mind there would be very much greater risk of explosion in a connection with a gully than if there was an outlet into the sewer, where there was always a continuous current of air. The report of the committee was then adopted, and it was decided to ask the company what size pipes they intended to go into the sewers.

Newport (Mon.).—The governors of the Newport Intermediate and Technical Schools have decided that the whole of the schools be lighted by electricity. The Newport Corporation have given the gas company notice that they can dispense with the 50 or 60 gas lamps in the area now supplied with electric arc lights, and the gas company is understood to have asked that the Corporation should light up the Corporation-road so as to bring up the consumption of gas for public lighting to the old standard quantity. The Lighting Committee, which has charge of the business, have given hurried directions as to the possibility of lighting the whole of the streets of the borough with electricity, incandescent or arc light, as the occasion might require There the matter stands at present.

The Telegraph Manufacturing Company, Limited, of Britannia Telegraph Works, Helsby, near Warrington, etc., inform us that in consequence of the heavy advance in raw materials they are under the necessity of reducing the discounts on their electric light cables and wires by 10 per cent. from date, and in cases where their invoices have been net prices will be increased by 10 per cent. Customers are also requested to note that existing terms for packages and carriage for cables and wires are now cancelled, and that in future the company will only pay carriage on consignments weighing not less than ½cwt. and all drums and packages will be invoiced at cost price, two-thirds the amount being credited if returned (carriage paid) in good condition and duly advised.

Radnor.—The County Council have received a communication from the General Post Office asking the Council to consent to the erection and maintenance of a line of telegraphs from Boughrood Station to Llyswen Post Office. Dr. Harding moved that the request be granted, and suggested that the Council should take the opportunity of pointing out to the postal authorities that the telegraph facilities for the county were wholly insufficient. Between Kington and Rhayader, a distance of 25½ miles, there was not a single telegraph office erected and maintained at public expense Mr. P. Lloyd added that there was no telegraphic communication between Builth and Glasbury. The motion of Dr. Harding was agreed to, and the clerk was directed to point out the inconvenient state of the telegraph service in the county.

J C Howell, Limited.—The *London Gazette* announces that the firm of J. C. Howell Limited, electric light and power engineers, of 24, Queen Victoria-street, London, E.C., and at Llanelly, have gone into voluntary liquidation. We understand that this has only been done in order to effect a dissolution of partnership between the two managing directors, Mr. J. C. Howell and Mr. Wm. Meredith, in consequence of which Mr Meredith retires from any share in the management of this business. The assets of the old company will be taken over by a new company of the same name, and the usual business will be continued without any interruption on precisely the same lines as hitherto. The liabilities of the old company will be discharged by the liquidator, Mr. S. F. Isitt, of 6, Old Jewry, E C., in due course.

Leeds.—The Highways Committee of the Leeds City Council have confirmed the decision of the Tramways Committee to engage Dr. Hopkinson to report upon the suggested experimental electric tramway line in the city. His engagement, however, will be subject to the sanction of the City Council, which it is proposed to obtain to-morrow (Saturday). A question was asked as to why the choice of the sub-committee had fallen upon Dr. Hopkinson, and the reply was given that he is one of the leading electricians in London, and had previously been employed on behalf of the Corporation. Moreover, it was stated that he is not in any way connected with manufacturers, and therefore has no patents to push. It was generally felt at the meeting that the engagement of Dr. Hopkinson will be of distinct advantage to the Corporation in reference to the experimental trial of electricity as a motor on a portion of the city tramways.

Exeter.—The City Council have received a communication from the Board of Trade laying down the conditions under which they would be prepared to consider the revocation of the electric lighting order granted to the Exeter Electric Light Company in view of the purchase of the undertaking by the Council. It was proposed and seconded that the letter be referred to the Electric Lighting Committee. Mr. Varwell said that he was more than ever convinced that this was to be a committee of meddle and muddle, and that they would be mixing themselves up in a matter

Digitized by Google

they did not understand. It was not fair either to put this extra work on the surveyor. Mr. Perry said under the conditional contract entered into they were bound to have the committee. Machinery would have to be purchased, and it was necessary to have someone to see that the Council would not be landed in a greater expense than they anticipated. The motion was agreed to.

Peterborough.—The Lighting Committee of the Corporation have stated that the engineer had reported on the scheme for electric lighting, prepared by him in consultation with Dr. Fleming, and recommended that application be made to the Local Government Board for sanction to borrow £20,000 for the proposed works. Mr. Batten proposed in committee that the engineer reconsider and revise his estimate, and that the members of the committee be provided with copies thereof and also copies of his previous report and estimate, and that the matter be then reconsidered. This was seconded by Mr. Herbert and carried At a subsequent meeting of the committee some discussion took place as to the engineer's recommendation with reference to the amount of loan for which the Local Government Board's sanction should be applied for, and the consideration of the matter was adjourned for the information ordered to be given at the previous meeting to be supplied.

Gloucester.—A deputation have reported to the Town Council that they visited Bristol and inspected the electric lighting installation of the Corporation, and the electric traction installation and the electric tramway of the Bristol Tramway Company, when the various arrangements were fully explained by Mr. George White, the managing director of the tramway company, and the engineers having the control of the works. Mr. George White, with Mr. Kincaid and Mr. Devonshire, attended before the committees and explained the views of the tramway company as to a combined scheme for electric lighting and traction, and explained the lines on which the tramway company and the Corporation might co-operate in carrying out such a scheme. After discussing various details the further consideration of the matter was adjourned in order that further information may be obtained and laid before the committees, prior to the special meeting of the Council to be held on November 12.

Bury St. Edmunds.—Mr. F. W. Turner, the local advocate of electricity, writes to a local paper as follows: "Bury St. Edmunds is most favourably situated for lighting by electricity, being, as it were, in a ring fence without much outlying suburban population. Should the Council allow this opportunity to pass, a company will doubtless obtain a provisional order to light the town, for although Section 1 of the Electric Lighting Act of 1888 protects local authorities, the Board of Trade will not allow any local authority to stand in the way of progress. As a case in point, the Bedford Corporation obtained a provisional order in 1890, but they did not for some years take advantage of the powers given them. A company came upon the scene, and in consequence a deputation from the Council attended the Board of Trade, when Sir Courtenay Boyle said: 'If the Corporation would pass a resolution to supply electricity their order will stand, but if they will not do so within six months their consent will be dispensed with and an order will be granted to a company.'"

Dewsbury.—The Mayor said at the last Town Council meeting that, with regard to the electric light fittings at the new baths and library, the tenders placed before the committee had been fully considered. The committee hoped that some local firm would put in a tender that would enable the work to remain in the town, but from the tenders sent in they did not consider themselves justified in giving the work to a local firm, as the lowest price of the Dewsbury firm exceeded the lowest price sent in by a Bradford electrician, and they felt obliged to accept the lowest tender. He might say they were perfectly satisfied with the Bradford gentleman who had been accepted, as other important works had been carried out by him in other places The difference in the tender was £11. A correspondent writes: "A white elephant! That, according to Councillor Baker and others, was what the Dewsbury electric lighting installation would prove It is gratifying to the promoters to know the 'elephant' is now almost self-supporting, and that in a few months it will probably be earning a profit that may be expected to increase annually. The Heckmondwike Local Authority might have done well to go in for a similar scheme when they had an opportunity. It is said by many, however, that vested interests were too strong. Heckmondwike wants something to make its Market-place more attractive, on Saturday nights especially, and what better could the Council have had than a brilliant illuminant?"

Belfast.—The Town Council have passed the Electric Lighting Committee's report, which contained the following: "Your committee have ordered the extension of the electric light mains to College-square East, Wellington-place, Howard-street, and Arthur-street. They have accepted the tender of the Acme Gas-engine Company to supply and erect two sets of direct-coupled engines and dynamos, rendered necessary by the increasing demand for current. They have requested Prof. Kennedy to represent the Council at the meeting to be held by the Board of Trade to consider the revised draft regulations for securing the safety of the public." In reply to Councillor Herdman, Alderman Pirrie said the committee were pleased to say that all the light that their plant was capable of producing had been applied for. They had on the Electric Committee the able assistance of the Gas Committee. A member of the Council, Mr. Young, had tried to show that the electric light would not be called upon to any considerable extent, but they had ordered two additional engines of 150 h.p. each, which would give them 50 per cent. additional light or 5,000 additional lamps. Electric light was not done, as Mr. Young had told them, but it had a greater future before it than gas, for he believed nine-tenths of their buildings would be lighted by electricity when the committee had permission to put down a large and proper installation.

Birmingham.—With reference to the meeting which has been held to protest against the proposed tramway to Nechells on the overhead conductor system, a correspondent writes to the *Birmingham Daily Post*: "The Nechells controversy in your journal proves once again how extremely difficult it is to remove the prejudices of the English people. We were a decade—shall I say decades?—behind the rest of the world in the establishment of the tramway system in this country, the cause being British prejudice against an innovation. It is now the same with regard to the overhead system. How anyone can hesitate for a moment between the horrible van demon called a steam tram and the overhead system, I cannot imagine Even the trotting horse is not to be compared with it. As to the disfigurement question, it can pretty safely be asserted that this is all a bogey. Have any of your readers visited Brussels lately and seen the overhead system in use there? Brussels is a noble city of splendid avenues, and yet the authorities have not hesitated to adopt the overhead trolley on some of its fine avenues, and the disfigurement does not exist. The pillars there are artistic, and why should not the Corporation of Birmingham insist upon beautiful pillars being erected on the Nechells route? I have no hesitation in saying that once the overhead system is tried in one section of Birmingham in will soon spread, say, to the Bristol and Hagley roads. I see that the Americans have devised a novel system of underground electric traction; all that is visible to the naked eye is a double row of iron contact plugs lying nearly flush with the track," etc.

Copper.—The latest mail reports on the American copper market say that the recent large purchases of Lake Superior ingot at 12c. amounted to nearly 3,000,000lb., if not more, and not to 2,000,000lb., as previously stated. Purchases could still be made at 12c., and indeed buyers at that price were scarce. Business had become moderate in volume, and demand spiritless. Messrs. James Lewis and Son, of Liverpool, in their monthly report say: Some 3,000 or 4,000 tons of American argentiferous pig copper have been sold for forward delivery, and a considerable quantity of Arizona bars were also offered, and realised 5s. to 7s 6d. per ton premium over G.M copper. About 2 000 tons of American argentiferous matte have also been sold during the past month. In New York the value of Lake copper has declined from 12·25 to 11 75 cents per pound. Shipments to Europe for the past month are about 3,920 tons. Imports are 5,694 tons less and deliveries 4,380 tons greater to date than during the same period last year. The total arrivals in England and France for the month have been 7 674 tons, and the deliveries 10 084 tons fine. Stocks have decreased 2,410 tons The arrivals in England from Chile during the month have been 1 566 and the deliveries 2,497 tons fine, and from other countries 3,197 and 4,701 tons fine respectively. The arrivals in England from the United States have been 122 tons bars 53 tons ingots, and 828 tons matte, equal to about 653 tons fine copper, and in France 270 tons fine. The Chile charters for the month are advised as 2,300 tons, and exchange 17⅜d. Sales of furnace material have been confined to: October 2, 55 tons ore, Portuguese, about 11 per cent., to arrive in Liverpool, on private terms.

Bangor (N.W.).—A special meeting of the Bangor City Council has been called to discuss the electric lighting question. Dr. Grey Edwards said that the question had been thoroughly discussed at a previous meeting of the Council, when a resolution was passed that the Electric Lighting Committee be empowered to proceed at once with the scheme in order to be in a position to open electric light works at the end of 1896 They had now to decide whether to give Mr. Medhurst instructions to proceed with the plans at once. The importance of having the light by the end of 1896 was, he said, patent to everyone. The increased demand for light in Bangor was such that they must do something definite. They had been considering that question for the last nine or ten months, and they ought now to arrive at a decision. He moved that instructions be given to Mr. Medhurst to proceed with the plans and specifications, and he hoped they would unite to carry the scheme through. He believed that the majority of the Council were convinced that they should at once go on with the scheme. The small cost of the license would compensate them, as without it they would have to wait until 1897. There were several people who were undecided whether to put in gas or electric light in their houses. He firmly believed it would be of the greatest advantage to the town in every way. Some people advised them to wait until they received revenue from the pier, but he maintained that nothing would pay so well as having the electric light on the pier. At Aberystwyth, for instance, the pier had paid three times as well since the pier and the promenade were lighted with electricity. In Bangor they should go in for the electric light because they had the pier. Mr. E. Clarke seconded the motion. Dr. Edwards's motion was eventually carried, twelve voting for and eight against.

New London Mains.—The Highways Committee of the London County Council reported on Tuesday the receipt of a notice dated October 18, from the Vestry of Hampstead, under the Hampstead Electric Lighting Order, 1892, of intention to lay mains on the east side of Abbey-road, from Alexandra-road to Boundary-road, and on the north side of Boundary-road from Abbey road. The committee have considered a notice, dated October 19, from the County of London and Brush Provincial Electric Lighting Company, of intention, under the County of London (North) Order, to lay conduits for electric conductors from the south-east corner of Farringdon-road to and across Vine street Bridge and alongside

Digitized by Google

the Sessions House to Turnmill-street. They saw no objection to the proposed works. They have also considered two notices, dated October 24 and 29 respectively, from the House-to-House Electric Light Supply Company, of intention to lay mains (*a*) on the south side of Wetherby-road; (*b*) in and across Drayton-gardens. The proposed works were unobjectionable. Also a notice, dated October 30, from the St James's and Pall Mall Electric Light Company of intention to lay mains acro's Carnaby-street, in Ganton-street, King-street West, and Argyll-place. According to the plan, the company also propose to cross Regent-street, which appears to be outside the company's area of supply, and the committee were of opinion that the Council's consent should be limited to the portion within such area. The Vestry of St. Pancras have given a notice, dated October 28, of intention to lay mains in and across Great College-street and in Highgate-road. The proposed works were unobjectionable. The committee have also considered a notice, dated October 30 from the Kensington and Knightsbridge Electric Lighting Company, of intention to lay mains in Queensgate-place-mews. They saw no objection to the proposed works.

Stafford.—A correspondent writes: "The lighting of the new County Council buildings is by means of current supplied from the Stafford Corporation mains These are led into the cellars beneath the officials' entrance, where the main throw-over switch is placed; thence the mains are led to the main switchboard in the porter's box, where the current is divided into five circuits, each circuit being provided with a double-pole switch and cut-out. From this board the branch mains are led to the various parts of the building where the distribution-boards are fixed and to which the branch mains are severally connected. No. 1 distribution-board controls the lights in the basement and the electric motors for driving the hot-air and ventilating fans, and probably this circuit will never be cut off, as light will be wanted in the cellars all the year round, and the ventilating motors will be wanted summer and winter. Board No. 2 controls the light in the ground-floor offices, board No. 3 the members' entrance-hall, board No. 4 the committee-rooms, and board No. 5 the Council-hall lights. From the distribution-boards branch wires are led to the various lamps, seven lamps as a rule being placed on each branch circuit. The wires throughout the building are concealed behind the plaster, except in back staircases and other places where the appearance of wooden casing is not objectionable. In all concealed work the casings are laid sufficiently large so that the wires may be withdrawn if necessary The fittings are of plain brass and have a peculiarly graceful appearance. The lamps, which are all frosted, hang from silk cords below the metalwork. The members' entrance-hall is lighted in the daytime by means of a glass dome with skylight above. The dome is glazed with stained glass, and on the top side are a number of electric lamps. Thus light is obtained without glare, and the *summum bonum* of the lighting engineer's ambition—*i.e.*, imitation daylight—arrived at. The general lighting is very effective. The whole contract has been carried out by Mr. W. O. Rooper, C E, of Stafford.

Brazilian Telegraphs.—The following correspondence has taken place in the *Times*: "Brazilian Submarine Telegraph Company, Limited, Winchester House, Old Broad-street E C, November 1. Sir,—In your issue of to-day is a letter from the Western and Brazilian Telegraph Company, Limited, in which it is stated that the tension existing in the present position of the Brazilian Submarine Telegraph Company in Brazil *vis-a-vis* the Brazilian Government referred to at the ordinary general meeting of the members of this company held on Wednesday last is explained in an official report of the Brazilian Telegraph Department, dated August 15 last, as being due to the action of Sir John Pender in relation to the island of Trinidad. I am instructed to state that, so far from this being the case, the differences of opinion between my company and the Brazilian Government commenced in 1892, and were increased in 1893, when a tax was imposed upon our traffic, and were further added to in 1894 by the treatment this company's agent, who was sent specially to Brazil to negotiate with the Government for a removal of all misunderstandings, received at the hands of the Government officials. The Western and Brazilian Telegraph Company, Limited, have always been well informed of all these matters which relate to our joint interests, so that it is strange they should have published so erroneous a statement with regard to the Trinidad incident, which only arose during the current year of 1895. (By order) RICHARD COLLETT, secretary" "The Western and Brazilian Telegraph Company, Limited, Blomfield House, London-wall, E.C., November 2. Sir,—In reply to the letter from the Brazilian Submarine Telegraph Company, I desire to say that for whatever period differences may have existed between the Brazilian Government and the Brazilian Submarine Telegraph Company they are in no way attributable to any action of this company, which has always desired and has always striven to maintain the most friendly relations with the Brazilian Submarine Telegraph Company. As respects the present tension, however, between the Government and that company, the report of the Director-General of the Government Telegraphs will speak for itself.—R. M. CUNNINGHAM, secretary."

Improved Accumulators—Dr. E. Sieg recently described before a meeting of the Elektrotechnische Gesellschaft of Cologne a new kind of battery made at the Cologne Accumulatorenfabrik. It is claimed that the difficulties connected with the casting of the Hagen lattice grid have been overcome by the use of an improved mould which allows of the easy withdrawal of the casting, but even with this improvement it is not possible to cast grids of a less thickness than 4mm., so in the construction of the negative plates the firm employ the form patented by Herr Aloys Zettler, of Munich, which allows of a still thinner lattice. The ever increasing need for portable accumulators has led the company to pay special attention to this type, of which they now consider they have a very good practical form. The plates are kept apart by perforated, waved celluloid separators, which form of construction gives great resistance to lateral pressure, while allowing the electrolyte to circulate. The distance between the plates is reduced to from 2½mm to 3mm. The cells are formed of hardened lead, and are closed with soldered covers. These batteries are claimed to be well adapted for both traction and lighting purposes. The Marienburg Railway uses the Cologne accumulators. Each carriage contains a battery of eight cells. Four wooden cases, each holding two cells with six positive and seven negative plates of 15cm. by 18cm., are connected, and put into a wooden case. Wooden ledges on the front and back of the case press against indiarubber bands, and prevent any movement of the cells. Their capacity is 108 ampere-hours, with 15 volts and 28 amperes maximum discharging current, the charging current being 18 amperes, and the weight 170 kilogrammes (374lb.) The high rate of charge which can be employed with the lattice grid is a special advantage, as the cells can be charged in six hours whilst the German Post Office accumulators require 22 hours. On the Marienburg Railway the accumulators not only serve for the lighting of the trains, but also for that of the platform, the front and end passenger carriages being provided with an arm at each side, by which a 20-c.p. lamp is automatically lighted. The sole agents for the United Kingdom and the Colonies of these accumulators are Messrs. Conze and Simon, of 52, Queen Victoria-street, London, E C.

Wimbledon.—The Local Government Board enquiry into the application of the Urban District Council for sanction to borrow £32,000 for purposes of electric lighting has been conducted by Major-General Phipps Carey, R E. Mr. Fletcher Moulton, Q C., instructed by Mr. W. H. Whitfield, the clerk to the District Council, appeared in support of the application, and it was opposed on behalf of the Ratepayers' Association by Mr. Castle, Q C., and Mr. Fordham Spence. All the members of the District Council were present with one exception. Mr. Fletcher Moulton, Q.C., said he appeared on behalf of the Wimbledon Urban District Council to support their application for the sanction of the Local Government Board to the loan of £32,000, in order to establish a system of electric lighting in the district under their control. Mr. Arthur Preece, A M.I.E.E., stated that he had been connected with his father, Mr. W. H. Preece, in eight or nine electric lighting schemes, including that of Kingston He had acted as his father's sole assistant and was responsible for getting out all the drawings. In his scheme for lighting Wimbledon with electricity the sums put down for capital were amply sufficient to cover the outlay, and the sums he had put down as working expenses were also sufficient. Mr. Manville, M.I.E E, said he had examined Mr Preece's report and heard his evidence, which he fully endorsed. He had fully satisfied himself as to the efficiency of the incandescent electric light for street-lighting, which had proved most successful at Portsmouth, where it was being greatly extended, and it was also being adopted in other large towns, including Swansea and Southampton, as well as Shoreditch. The working cost at Portsmouth was the lowest in the kingdom, which was attributable to the fact that half the current used was consumed in the public lighting, which was constant and reliable. He had not the least doubt that the incandescent light would be much more used for public lighting in the future. He recommended it in every case, and it was most favourable for public authorities. With regard to private lighting, he thought Mr. Preece's estimate was greatly under the mark. His own experience would have led him to double the number of lights for which there would be a demand. He believed there would be a very considerable demand for the electric light for houses under £40 a year. At Portsmouth, in a single street, they had over 1,000 lamps installed, and it was found there that many of the shops and houses only had from two to eight lights. Mr. W. H. Preece, C.B., C.E., past-president of the Institution of Electrical Engineers, and chief electrician to the General Post Office, corroborated the previous evidence, and said in his judgment the incandescent electric light was eminently efficient and economical for public street-lighting. Wimbledon could be lighted far more effectively than at present by means of the incandescent electric system, and at only a slight increase upon the present cost. The incandescent gaslight, so far from seriously competing with the electric light, was doing it an immense amount of good As a matter of fact and experience, the electric light was even cheaper than incandescent gas. He should advocate arc lighting in Wimbledon, as he had done in Kingston, if the conditions were similar. He was a very strong advocate of arc lighting, chiefly because it was such a splendid advertisement for the electric light. Arc lamps could be run from the same mains as the incandescent lamps, so that if it was determined at any future time to establish any number of arc lamps, it could be done. Mr. W. Santo Crimp, C.E, a member of the District Council, said he was very strongly in favour of this scheme, which he believed would be most beneficial to the ratepayers generally. Prof. Silvanus Thompson, M I.E E., described the scheme as a very crude one. It had some good features, but it would prove much too expensive. The figures in the estimate, as compared with the actual expenditure of other municipalities, were too low. Taking the public lighting part of the scheme alone, it would in his judgment be possible to work it much more economically than was proposed. In the series system, assuming that the same number of lamps were to be used over the same area, he thought it would be possible to save £3,000 or £4,000 in the capital outlay. He thought the estimate of 10s. per lamp as the average amount of revenue was excessive. He was a believer in the series system

Digitized by Google

for the outlying districts, as he thought it would bring public incandescent lighting to districts which no other system could touch. Mr. W. G. Cooke, chairman of the Ratepayers' Association, repeated his grounds for opposing the scheme, which have frequently been made public. He considered that the estimate was too roseate, that no allowance was made for renewals, and that nearly all the benefits would be absorbed by North Wimbledon. Mr. Moulton, Q.C., having again addressed the inspector on behalf of the Council, the enquiry terminated.

PROVISIONAL PATENTS, 1895.

OCTOBER 28.

20288. **Improvements in electric railways.** William Sharkey Hull, 323, High Holborn, London. (Complete specification.)

20301. **An improved machine for sweeping and cleaning chimneys, also for pushing and dragging lines or ropes through tubes or pipes for electrical or other purposes.** David Walker, 28, Calabria-road, Highbury, London.

20306. **Improvements in electric power storage batteries or accumulators.** Jacobus Langelaan, Barmen, Germany. (Complete specification.)

OCTOBER 29.

20335. **Improvements in electric arc lamps.** Percy Collinson, Sunbridge-chambers, Bradford.

20392. **Improvements in and relating to arc lamps.** Malone Wheless, 77, Chancery-lane, London. (Complete specification.)

20431. **Improvements in secondary batteries** John Joseph Rooney, 40, Chancery-lane, London. (Complete specification.)

20435. **Improvements in electric brakes.** James Devonshire, 70, Chancery lane, London (Frank E. Case, United States.) (Complete specification.)

OCTOBER 30.

20487. **Improvements in connection with electric indicators for signalling between signal-box and station platform.** Edward Wilson Cheyney, Police Office, Waterloo Station, London.

20498. **The novel application of electricity for lighting purposes.** Charles Henry Taylor and Joseph Taylor, 18, Bishopsgate-street Without, London.

20508. **Improvements in non-synchronous alternate-current motors.** Valeré Alfred Fynn and Easton, Anderson, and Goolden, Limited, 1, Queen Victoria-street, London.

20509. **An improved system and means for electrical distribution by alternating currents** Valeré Alfred Fynn and Easton, Anderson, and Goolden, Limited, 1, Queen Victoria-street, London.

20510. **Improvements in dynamos and motors.** Valeré Alfred Fynn and Easton, Anderson, and Goolden, Limited, 1, Queen Victoria-street, London.

20529. **Improvements in the construction of electric railways.** Michelangelo Cattori, 37, Chancery-lane, London. (Complete specification.)

OCTOBER 31.

20542. **Improvements in or connected with apparatus for the electrolytic decomposition of brine.** George Bell and George William Bell, 15, Water-street, Liverpool

20572. **Improvements in and relating to the active material for secondary electric batteries.** Carl Marschner, 37, Chancery-lane, London.

20584. **An improved dynamo-meter or power measurer.** Frederick John Cox, 11, Burlington chambers, Birmingham.

29595. **A device for improving the contact of the wires connecting the several rails of electric tramways.** Carl Dietrich Hastedt, 18, Buckingham-street, Strand, London.

20600. **Improvements in electric incandescent glow lamps.** Reuben James Bott, 9, Park-place-villas, St. Mary's, Paddington, London.

NOVEMBER 1.

20626. **Improvements in electric arc lamps, specially applicable for lantern purposes.** Frederick Woodward Branson, 30, Park-row, Leeds.

20636. **Improvements in or relating to telephone instruments.** Thomas Frederick John Truss, 10, St George's-crescent, Liverpool.

20639. **An improved system of wiring buildings and other places for the fitting up of electric light installations.** John Jennings and Ernest Wilfred Lawson Harrison, 53, Arcade-chambers, St. Mary's Gate, Manchester.

20681. **Improvements in and relating to the ventilation of transformer-boxes, road and junction boxes, conduits, and the like, used in the distribution of electrical energy.** Leonard Penson, 433, Strand, London.

20696. **Improvements in electric switches.** Francis Henry Nalder and Alfred Soames, 24, Southampton-buildings, Chancery-lane, London.

NOVEMBER 2.

20719. **An electric maximum current indicator.** Frederick William Edmund Jones, 23, Archery-road, Leamington Spa.

20728. **Improvements in electric tramcar system.** Alfred Charles Brown and George Richard Neilson, 50, Old Broad-street, London.

20734. **Improved bowl for electric and other lamps.** Alfred Julius Boult, 323, High Holborn, London. (John Lawrence Spink and Thomas Walter Horn, Canada.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1890.

1110. **Galvanic batteries.** Hitchcock. (Burnley.) (Second edition.)

1891.

17324.* **Electric lighting.** G. J. and G. J. T. J. Parfitt. (Amended specification.)

1894.

17065 **Electric cables, etc.** De Ferranti.

19364 **Electromotors, etc.** Connors and Langdon-Davies.

20354. **Electro-deposition of aluminium, etc.** Marino.

21879. **Effecting electro-fusion of metals.** Thwaite and Allen.

23661. **Electric telegraph instruments.** Willmot.

23685. **Brackets for telegraph poles.** Siemens Bros. and Co., Limited, and Perry.

24714 **Secondary voltaic batteries.** Epstein.

25145. **Producing copper by electrolysis.** Mewburn. (Société L'Electrolyse.)

1895.

5878. **Distributing electricity.** Wordingham.

6000. **Electrically lighting miners' safety lamps.** Peel.

10836. **Storage batteries** Payen (Second edition.)

15246 **Incandescent lamp mantles.** Crocker.

16077. **Electromagnetic percussive tools.** Thompson. (Fonda.)

16343. **Incandescent lamps.** Baermann.

16702. **Secondary voltaic batteries.** Vandersmissen.

16924. **Electric fire alarms.** Tisdale and Gould.

16925. **Electric fire alarms.** Tisdale and Gould.

16939. **Electric locomotives.** Devonshire. (Rice.)

NOTES.

Congress and the Electric Light.—An installation has just been made at the Washington Capitol in order to light the halls of the Senate and House of Representatives with electricity.

Telephonic Communication between Berlin and Vienna is to be reinforced next spring by the laying of a second line, for which the Austrian Government has voted a credit of 300,000fl.

Solder for Aluminium.—Mr. Joseph Richards, in a paper read before the Franklin Institute, Philadelphia, states that he has found that the best solder for aluminium is an alloy corresponding to the formula Sn_4Zn_3.

Dundee Institute.—The council of the Dundee Institute of Architecture, Science, and Art announce that the annual conversazione will be held, by permission of the Fine Art Committee, in the Victoria Art Galleries, on the evening of Thursday, 21st inst.

The Discovery of Argon.—Lord Rayleigh and Prof. William Ramsay have received from the United States Embassy a cheque for 10,000dol., which had been granted by the Smithsonian Institute at Washington as the first Hodgkins prize for their memoir on argon.

Electric Traction in Paris.—We understand that it has been definitely decided to adopt electric traction on the tramways in the Seine division of Paris. The trolley system will be used outside the fortifications, and it is proposed to give the accumulator system a trial inside these boundaries.

Institution of Electrical Engineers.—We are informed that the annual dinner, which was to have taken place on Friday, November 29, has been postponed until Friday, December 13, when H.R.H. the Duke of Cambridge will honour the Institution with his company. A circular to this effect is being issued to the members.

The Electrical Fan in Colombo.—With the introduction of electric lighting in certain public buildings in Colombo, we understand that the time-honoured punkah has been superseded by electric fans. These are connected with the lighting mains, and no sooner are they turned on than sufficient draught is created to cool the whole room.

King Khama and the "Lightning."—To the amiable coloured princes whom we have had and still have with us nothing has been more puzzling than our electrical installations and the subtle power of the electric current. The Shahzada gaze utterance to some highly funny remarks on the subject, and now we have Khama expressing grave wonderment that we "work lightning with our hands and our feet!"

North-East Coast Institute of Engineers and Shipbuilders.—At a meeting of the graduate section of this society at Newcastle yesterday, a paper was read by Mr. J. B. Bent on "Alternating-Current Motors for Use on Single-Phase Mains." The graduates' annual dinner will take place on Saturday, December 7. The third business meeting of the session will be held in Sunderland on Saturday, December 14.

Royal Institution.—The Christmas course of lectures, adapted to a juvenile auditory at the Royal Institution, will be delivered this year by Prof. John Gray McKendrick, M.D., LL.D., F.R.S., professor of physiology in the University of Glasgow, and formerly Fullerian professor of physiology in the Royal Institution. The subject will be "Sound, Hearing, and Speech," and the lectures will be experimentally illustrated. The first lecture will be delivered on Saturday, December 28, at 3 o'clock, and the remaining lectures on December 31, 1895, and on January 2, 4, 7, and 9, 1896.

A New Storage Battery.—A description of a new type of storage battery is going round the American electrical Press. A porous plate is produced by mixing lead and pumice stone while the lead is in a semi-molten condition. The plastic mass is then pressed into a mould, and afterwards, we presume, is formed on the Planté system. The pumice stone is left in. A high capacity per pound is claimed, but is supported by maker's figures only.

Coefficient of Magnetic Dispersion in Multiphase Motors.—Prof. Blondel calls attention to the coefficient used by Dr. Behn-Eschenburg in his theory of multiphase motors, and claims that one of the objections to it is that nothing is said about the nature of the coefficient, or what effect the primary and secondary circuits have on it, also that it leads to a number of errors, and that diagrams based on it are not exact. The whole matter at once becomes clear if instead of the coefficient of induction one introduces directly the magnetic flux, as is done by Hopkinson in his theory of transformers.

Presentation.—On the evening of the 9th a large number of the staff and workmen of Messrs. Ernest Scott and Mountain met at the Collingwood Restaurant, Newcastle, for the purpose of presenting Mr. M. B. Mountain, their works manager, with a token of esteem on the occasion of his marriage. Mr. Wile made the presentation, Mr. Mountain suitably responding and thanking all for their kindness. The present consisted of a silver set of dessert knives and forks, a silver set of fish knives and forks, and also a small spirit case. After the presentation a good programme was provided by some of the employés and a very pleasant evening spent.

Presentation to Sir David Salomons.—Sir David Salomons, who, together with his celebrated engine and dynamo house, was *Sketch*-ed the other week, has been the recipient from the Town Council of Tunbridge Wells of a lengthy illuminated address "setting forth his many good qualities as mayor and his high repute as an electrician and scientist." In thanking the Council for the gift, Sir David said that the unexpected had happened to himself, for 50 years ago, when he came to Tunbridge Wells a tall, lean boy, he little thought he should live to have the honour of being the mayor of Tunbridge Wells; and he incidentally remarked that he should always continue to be interested in the development of the town, especially in connection with the electric light.

The Coming Conference on Light Railways.—Mr. J. Wallis Davies writes from 16, Parliament-street, S.W., under date November 12, stating that the object of the coming conference on light railways, to be held at the Westminster Palace Hotel on Thursday, the 28th inst., under the presidency of Sir Albert K. Rollit, M.P., will be to discuss the furtherance of legislation on that subject. With the view of making the discussion as practical as possible, it has been decided to take the Bill introduced on the subject by the late Government as a basis of discussion. Proposed amendments or substantive clauses in this Bill should reach Mr. Davies not later than Tuesday morning, the 26th inst. It is also desired that those intending to be present at the conference should communicate with Mr. Davies at once.

Electric Traction on Canals.—An official test of a plan for propelling canal boats by electricity has been made at Tonawanda (New York), near where the Erie Canal connects with the Niagara River and Lake Erie, and there is every promise of useful and lasting results. The system used is that of hauling from the bank, as distinguished from driving the boat by a propeller immersed in the water of

Digitized by Google

the canal, and has been devised by Mr. Richard Lamb, C.E., and is similar to one which has already been in use elsewhere for canal work and logging in swamps. A 500-volt current is used. At present no data are to hand showing the efficiency of the electrical apparatus, nor is there any other means at hand of making a comparison with the older methods of traction which it is hoped to supplant. But it is said that the State officials and experts present were very favourably impressed with the results of the trials.

The Royal Society.—The following is a list of those who have been recommended by the president and council of the Royal Society for election into the council for the year 1896 at the anniversary meeting on November 30: President, Sir Joseph Lister, F.R.C.S., D.C.L.; treasurer, Sir John Evans, K.C.B., D.C.L., LL.D.; secretaries, Prof. Michael Foster, M.A., M.D., Lord Rayleigh, M.A., D.C.L.; foreign secretary, Mr. Edward Frankland, D.C.L., LL.D.; other members of the council, Mr. William Crookes, F.C.S., Sir Joseph Fayrer, K.C.S.I., Mr. Lazarus Fletcher, M.A., Mr. Walter Holbrook Gaskell, M.D., Mr. William Huggins, D.C.L., Lord Kelvin, D.C.L., Prof. Alexander B. W. Kennedy, LL.D., Prof. Horace Lamb, M.A., Prof. Edwin Ray Lankester, M.A., Prof. Charles Lapworth, LL.D., Major Percy Alexander MacMahon, R.A., Prof. John Henry Poynting, D.Sc., Prof. Arthur William Rücker, M.A., Mr. Osbert Salvin, M.A., Prof. Harry Marshall Ward, D.Sc., Admiral William James Lloyd Wharton, C.B.

The Emperor William and Edison. — Here is another story concerning Kaiser Wilhelm's famous omniscience, which we hasten to reprodace before it is contradicted. When Edison, it is narrated, brought his phonograph to the Imperial palace in Berlin, by invitation, the Emperor took him into his private cabinet, no one else being present, carefully closed all the doors, and then besought him to take the marvellous invention apart and explain to him all its workings. This was done, and the inventor was invited to attend a Court reception next day and to bring the phonograph with him. Upon this occasion Thomas Alva found the Kaiser surrounded by a brilliant throng of nobles, each one decorated with the insignia of his rank. When he produced his mysterious device the Emperor took it in hand, eyed it critically, as though he had never seen it before, and then marched apart with it and explained to the amazed courtiers exactly how it performed its wonders! Not a word was said about his instruction of the day before.

"Autocars."—Mr. G. Croydon Marks, at the opening meeting of the session of the Birmingham Municipal Technical School Engineering Society, gave a lecture on "Horseless Vehicles." Councillor Martineau, who presided, said that in the matter of horseless vehicles England had been behind other nations. It was desirable not only that England should come to the front in this matter, but that Birmingham should come to the front among the towns in the kingdom. This, he believed, the Municipal Technical School would be the means of bringing about. Mr. Marks said that the first successful attempt to make a self-moving road vehicle must be credited to a Frenchman, Nicholas Joseph Cugnot, who was born in 1729. With the aid of an excellent series of 55 lantern slides, the lecturer described subsequent machines worked by steam, electricity, manual, or pedal power, or oil-engines, pointing out from the experience of successful inventors what to aim at and what to avoid, and showing that the greatest successes were obtained by those who combined with mechanical knowledge and skill a realisation of the practical requirements of road traffic.

Telegraphs in Japan.—The growth of the tele graphic system in Japan and the simultaneous growth of technical knowledge of the acts connected with the production of the necessary materials for its construction is well shown by the following facts. Twelve years ago a general scheme was prepared, embracing every city and town of importance and affording every prefect and subprefect the means of communicating with the central Government at the capital. This scheme was so carried out that it paid its way even after the first year, and now they have 8,430 miles of line and between six and seven hundred telegraph stations and offices. "Not a mile of this telegraphic network existed a quarter of a century ago, and at the outset every ton of the material required had to be imported from Great Britain or the Continent. Now the whole of it, with scarcely any exception, is manufactured in Japan, and the Japanese workshops and factories are able to supply such material to their neighbours," and the country possesses a telegraphic system which, "for perfection of organisation, despatch, and reliability combined with a low tariff, is nowhere excelled on the globe," though we may fairly claim equal merit for our own system.

The Electro-Harmonic Society.—A ladies' night has been fixed for Saturday, November 30, at the St. James's Hall Restaurant, Regent-street, W., at eight o'clock. The musical directors are Messrs. T. E. Gatehouse and A. E. Izard, and the programme is as follows: Duo concertante for pianoforte and violoncello, (Mendelssohn), Mr. Alfred E. Izard and Mr. W. C. Hann; song, "The Old Head of Kinsale" (F. Moir), Mr. Franklin Clive; dramatic scenette, "He Fought like a Demon," Mr. and Mrs. Frederic Upton; Russian song, "Vainka's Song" (Von Stutzman), Miss Ethel Bevans; sensational novel, Mr. Frederic Upton; violoncello solos, (*a*) "Sur le lac" (B. Godard), (*b*) "Elfentanz" (Popper), Mr. W. C. Hann; humorous selection, Mr. Cecil Barnard; vocal duet, "It was a Lover and His Lass" (Walthew), Miss Ethel Bevans and Mr. Franklin Clive; pianoforte solo, "Bolero" Op. 19 (Chopin), Mr. Alfred E. Izard; dramatic scenette, "I shall never leave this room alive," Mr. and Mrs. Frederic Upton; old song, "Tom, the Tinker" (Hatton), Mr. Franklin Clive; violoncello solo, "Fantasie sur Carmen" (Hollman), Mr. W. C. Hann; song, "This Green Lane" (Edith Cooke), Miss Ethel Bevans; humorous selection, Mr. Cecil Barnard.

Limits of Electric Power Transmission.—Mr. Alten D. Adams in an article on this subject in the New York *Engineering Magazine* of this month says that "in every branch of engineering there is a wide difference between the physically possible and the commercially practical, and the electric industry has suffered repeatedly from a failure to recognise this fact. During the past year much has been written which might leave the impression that the electric transmission of power over very considerable distances, up to several hundred miles, is a commercially practical undertaking; and that power from Niagara Falls or the coalfields of Pennsylvania can be delivered at the large cities of our Eastern States at a good profit to the promoter." His conclusion is that if alternating current generators and motors to work at 10,000 volts or over can be obtained, or if a number of continuous-current generators and motors are connected in series to attain the desired voltage, it is probable that there are many cases where the transmission of moderate amounts of power from 25 to 50 miles is commercially practical; but for excessively great distances, while "the electrical transmission of power can certainly be accomplished when expense is no object, it cannot compete commercially with that great vehicle of long-distance power transmission—an ordinary coal car."

Digitized by Google

The Metric System.—Mr. A. J. Balfour will on Wednesday, the 20th inst., receive a deputation from the Association of Chambers of Commerce in reference to the adoption of the metric system. The following memorial will be presented: "Your memorialists have for many years past taken a deep interest in the subject of decimal weights and measures, as evidenced by the repeated resolutions passed not only by individual Chambers but also by the associated Chambers, in favour of the adoption into this country of the metric system, and your memorialists are pleased to find that the Select Committee appointed by the House of Commons to enquire whether any and what changes in the present system of weights and measures should be adopted have recommended: (*a*) that the metric system of weights and measures be at once legalised for all purposes; (*b*) that after a lapse of two years the metric system be rendered compulsory by Act of Parliament; (*c*) that the metrical system of weights and measures be taught in all public elementary schools as a necessary and integral part of arithmetic, and that decimals be introduced at an earlier period of the school curriculum than is the case at present. Your memorialists therefore respectfully urge upon her Majesty's Government to carry out the recommendations of the Select Committee during the next session of Parliament, by bringing in a Bill for the purpose."

Long-Distance Telephony in India.—A correspondent to *Indian Engineering* considers that the recent "important experiments" in long-distance telephony conducted in India by the Government Telegraph Department, will appear to those at all intimately acquainted with the technique of this science as little more than a waste of time and public money. He states that the conditions under which such telephonic communication can be successfully established have long since been ascertained, and can be predetermined by calculation with sufficient precision for every practical purpose. This has been shown, for example, in the somewhat complicated combined submarine and aerial lines between Buenos Ayres and Montevideo, and also between London and Paris. It is correct that a bronze circuit, weighing about 650lb. per mile, would suffice as regards thickness for speaking between Bombay and Calcutta, but unless the lines be so laid as to counteract induction influences from earth currents and other wires it would be useless. If, moreover, it is in close proximity to powerful telegraph circuits, it is likely that on such a long line at least all the principal telegraph stations should have to be provided with Rysselberghe's graduators. A liberal use of this ingenious device, in combination with the separators of the same celebrated pioneer of long-distance telephony, would render a large number of our copper telegraph lines immediately available for telephonic communications without interference with the ordinary telegraphic work on the same.

A Marine Electric Locomotive.—The electric launch has up to the present been more of a luxury than a commercial competitor with the ocean greyhound. There are some, according to our namesake in New York, who believe that a broader field exists for electrical navigation, and indeed that sea-going vessels will some day be driven electrically. Among these is Mr. A. S. Hickley, of Asbury Park, N.J. It has been Mr. Hickley's idea for many years that the vessels that cross the Atlantic are making too slow time. The reason is, that they cannot drive their propellers fast enough with the amount of power behind them without shaking the boat to pieces. Mr. Hickley's plan is to put a powerful engine, say, a compound condensing Corliss engine of the slow-speed type, connected directly to a multipolar generator giving, say, 500 volts potential. Then directly upon the shafts of the propellers he would put the armatures of the motors which are to drive the propellers. These can easily be made to run from 600 to 900 revolutions per minute, whereas the engine is probably only making 60 to 80. It will be seen that in this way there would be scarcely any vibration in the ship, and the propellers dipping in and out of the water, caused by rough weather, would not affect the main engine and jar the vessel from stem to stern as at present. Mr. Hickley is about to conduct some experiments on this basis, and it will be a matter of surprise if he does not find the losses due to the double conversion more than those due to vibration when the propellers are driven direct by a steam-engine.

Electric Railways Driven by Gas-Engines.—Mr. Westinghouse has prepared a scheme for a trunk-line railway, using gas-engines and producer gas as the motive power, which he described to the directors of the Pennsylvania Railroad when they visited the Westinghouse works recently. He stated that "a strong argument heretofore used against the adoption of the electric system for main lines has been due to the fact that the investment required to make the change would be heavy without materially decreasing the consumption of fuel and other costs of operation—an objection which it is believed can be met by the development and use of gas-engines of large sizes instead of steam-engines for the generation of the electric current." After presenting arguments to show that the gas-engine would use but one-eighth the fuel of an ordinary locomotive to produce similar power, Mr. Westinghouse, continuing, said that "the Pennsylvania Railroad consumes about 5,000,000 tons of coal per annum on its lines east of Pittsburgh, taking, approximately, 20 loaded trains each day for its transportation, and consequently the return of 20 empty trains, and thus requiring for the service of the company alone fully 3,000 cars and a proportionate number of locomotives. If this power were to be generated by gas-engines, only about one-eighth or 600,000 tons of coal per year would be required, effecting a saving of over 4,000,000 tons of coal now costing the railway company above 5,000,000dol., a saving which would justify a large enough capital expenditure to cover the complete equipment of the railway. To carry out an arrangement of this character, stations having electric generating plants with gas-engines and producers could be located at intervals of from 10 to 12 miles, so that there would always be two or three stations furnishing current for any particular part of the line." The *Electrical Engineer* of New York gives further extracts from the speech of Mr. Westinghouse showing the other advantages of the electric system, such as increased speed and less wear on the permanent way.

Potential Drop.—The following on the "drop of the potential along the wire of a Ruhmkorff coil," by M. Wladimir de Nikolaieve, is from the *Journal de Physique* of last month. The author states that each turn is traversed by two magnetic fluxes: one is the magnetic induction along the core, and the other is the result of the self-induction of the coil. Each of these is stated by the author to be the same for every turn, the total E.M.F. in each turn being also thus the same. As the phase of the current at any moment is nearly the same in all the turns, it is seen that the current intensity and E.M.F. are the same for each turn; but the resistances of the turns are not the same, hence there must be something to equalise the currents in them, and this is nothing else than the drop of potential. Considering any single layer of the coil, and if r is its resistance, v the difference of potential between its extremities, E the E.M.F. of the magnetic induction, n the number of layers, and R the sum of the resistances of all the layers, then by

Digitized by Google

equating the intensity of the currents in the layer considered and in the entire coil, we have

$$\frac{E + v}{r} = \frac{n E}{R},$$

which gives

$$v = E\frac{n r - R}{R}.$$

This formula shows that there are two drops in opposite directions; in the interior layers the drop is opposed to E, and in the exterior ones it assists E. If the coil were a single turn of homogeneous resistance, there would be no drop, and the current would have no exterior field. But if the turn or ring were composed of two parts of the same length but of different resistances, each part would have its own drop. The value of this fall of potential can be calculated in the case of a sinusoidal current; it depends on the E.M.F. induced by the field of the iron cores and on the resistance and self-induction of the coils.

The Crandall Electric Signal.—What the New York *Electrical Review* of October 30 describes as a promising device for use on sea or land is the invention of Mr. L. S. Crandall, a well-known typewriter inventor. It is a sort of typewriter delivering its message, letter by letter, in mid-air or at any distant point in gigantic characters of light. The observer may be miles away and yet read the message with ease. The keyboard is manipulated precisely as in an ordinary typewriter, and its function is to switch in, or direct the current through, a series of distributing wires, which are carried in a cable to the monogram or display frame. According to a predetermined scheme the keys exercise a selective function and each one switches in the leading wires only, which connect with the members of the monogram constituting the letter of the alphabet which that particular key represents. By reference to the monogram, bearing in mind that each line of lamps in it is a member capable of separate electrical excitation, the reader may easily trace any letter of the alphabet in form so nearly conventional has to be readily understood. Thus, if on the keyboard the A button is pressed, the lamps of all the members of the monogram entering into that letter shine out simultaneously, while all other lamps upon the display frame remain dead. And so on for every letter. The observer has only to follow the letters as they flash out one after another to spell out the words of the message. It will be seen that this is a sort of visual telegraph, and that it may be made to talk in almost any language spoken by man. It is also serviceable for cypher writing according to any prearranged code. Our contemporary adds that commissions appointed by both the Army and Navy Departments of the United States Government have viewed the device and reported favourably upon it. The life-saving service has also endorsed it, together with the signal service of the United States Army and the New York State Militia. It is stated that signals flashed from this frame are visible with the naked eye for distances of from one to three miles, depending on the weather, and that with a glass the signals may easily be read up to 10 miles. We, however, fancy that we have heard of a similar invention which failed to achieve practical success.

Electricity at a Japanese Exhibition.—Electricity was largely used in connection with the recent Japanese National Industrial Exhibition in Kioto or Saikio. The Lake Biwa-Kioto Canal is crossed by several bridges near the exhibition ground. The water-power station and the incline along which boats with cargo were moved up and down on wheeled cradles posed as if they were exhibited machinery. The cradle is hauled by a steel rope passing round a drum, which is worked by electricity generated by the water power of the canal. At this incline the canal branches into two. The main canal for navigation descends 118ft. in 1,815ft. to the level of the city. Double lines of railways, consisting of flat-bottomed steel rails, weighing 75lb. per yard, on wooden sleepers, are laid The gauge is 8ft. 3in. Two cradles, each with eight wheels, are so arranged that one goes up while another is descending. The width of the boat is 7ft., and the length 45ft., the weight of cargo being from 10 to 15 tons. The time of passage of the cradle is about 12 minutes. The electric generating station is situated at the foot of the incline, near the Buddhist temple Nanzenji. Three iron pipes, with a diameter of 36in., are laid side by side. The total quantity of water to be used in the station is 240 cubic feet per second, with a fall of 120ft. When the full power is to be used, 20 120 h.p. Pelton waterwheels are to be constructed. At present only half of the wheels are being utilised. The Pelton wheels are belted with Edison, Thomson-Houston, and Brush dynamos, with countershafts between them. A three-phase Siemens and Halske dynamo was lately laid. Not only are the cradles moved up and down the canal incline by the electric motor, but the electric power is used for spinning, weaving, in the manufacture of clocks, watches, needles, lemonade, ice, in soda-water factories, rolling-mills, rice-mills, pumping water used in bath-houses, etc, which are situated within a circle of two miles from the power station. Besides these, the station supplies electricity in the daytime to the Kioto Electric Railway Company, and at night to the Kioto Electric Light Company. The cost of the power ranges from £4 to £12 per horse-power per year for daily rates of 12 hours; for 18 hours the increase is 30 per cent., and for 24 hours it is 50 per cent. The Lake Biwa is the largest lake in Japan, having an area of 500 square miles, and the canal begins at the south-west extremity of the lake in Otsu, and enters the first tunnel of 8,040ft. long near the famous temple of Miidera, running along the sides of the hills of Yamashina, and piercing two other tunnels, of which the respective lengths are 411ft. and 2,302ft. It is just below this third tunnel that the canal divides into two branches. From the pool at the foot of the incline the canal continues westwards and unites with the Kamo River Canal. The canal turns to the east, passing a little south of the Kobe-Tokio Railroad as far as the Inari station, whence it turns towards Fushimi and finally enters the Uji River. Of the total amount of water—300 cubic feet per second delivered by the canal—240 cubic feet go to the main canal and the remaining 60 cubic feet go to the branch canal, which leads northward at the head of the incline through the fourth tunnel; then it crosses the valley of the Imperial tomb by a handsome viaduct of 14 arches; then after passing two more tunnels it crosses the Takano and Kamo Rivers by syphons, and continues to Kogawa. The length of the canal is 27,690ft. The chief object of this branch canal is the irrigation of ricefields, though it is partly used for power, while the object of the main canal is to open the navigation and to produce electric power. The length of the main canal is 36,650ft., and the difference of the level is 140ft.

The Telephone in Holland.—Herr A. Kruyt has recently published in the Dutch journal *Electra* an elaborate article on telephony in Holland. The telephone systems come within four categories: (*a*) Systems which are erected within a township—(1) private, (2) public; (*b*) systems which connect suburbs and property outside the town limits with the town lines; (*c*) interurban connections; (*d*) international connections. From 1880 to 1884 the telegraph authorities granted 126 concessions for

Digitized by Google

private telephone lines; from 1885 to 1889, 123; and from 1890 to 1894, 100 concessions. The first license for the erection of a public telephone system was one for Amsterdam, accorded in November, 1880, to the International Bell Telephone Company. In February, 1881, this concession was transferred to the Nederlandsche Bell Telephoon Maatschappy of Amsterdam, which rapidly acquired licenses in other parts of Holland. There are at present in operation in Holland 30 town telephone systems; and others are in course of erection. The annexed table compares the rates and the extent of the traffic of the various telephonic systems in the Netherlands.

Town telephone system.	Annual subscription.	Central offices.	Public call offices.	No. of subscribers: Total.	No. of subscribers: In proportion to the population. One subscriber to inhabitants.

In December, 1887, some years after the installation of the interurban system in Great Britain, America, Germany, and Switzerland, the Bell Maatschappy obtained from the Dutch Government the first interurban privilege—for a line between Amsterdam on the one hand and Haarlem and Zaandam on the other. Other interurban lines have since been established, notably between Rotterdam and the capital. In less than five years the Bell Maatschappy had connected all their town systems with each other at a cost of 150,000fl., while the expense to the State for posts and insulators amounted to less than 85,000fl. According to the report of the telegraph authorities, the number of interurban conversations during the past five years and the State receipts have been:

	Conversations.	Receipts (fl.).
1890	49,531	17,130
1891	61,031	20,368
1892	71,833	23,179
1893	79,414	30,727
1894	85,147	37,214

These figures relate only to conversations between subscribers. The complete number of "telephonic interviews" during 1894 would probably be about 110,000.

Statue to Benjamin Franklin.—It is announced that a fine bronze statue of Benjamin Franklin will be placed in Lincoln Park, Chicago, the gift of the Hon. Joseph Medill. Accompanying his offer Mr. Medill sends a brief statement to the commissioners explaining his reason for desiring the placing of a suitable memorial of the great American patriot, scientist, and statesman in the public park, in which he says: "He is undoubtedly one of the three or four greatest men our country has produced. His name and fame are world-wide. His works will be of everlasting benefit to his countrymen. He reflects lustre on the American name. Holding him in this estimation, I have deemed it a personal duty to help keep his memory fresh in the minds of Chicago's youth." Upon this the *Western Electrician* of October 26 remarks: "This is a graceful tribute to the memory of a man the value of whose work in behalf of his country and in the interest of science is becoming more apparent as years roll by. That he was not fully appreciated in his day is not strange; few great men are, and there are very few whose work has been of such great value as was that of this eminent American. We must remember, too, that in his own country not only was he without an equal, but there were very few who were capable of properly estimating his great ability. In England and in France, the scenes of his most important diplomatic achievements, his reputation was established by actual comparison with the leading men of the two most powerful nations of his time. When it is remembered that his introduction at the Court of Louis XVI. was the occasion of much mirth among the gay attendants, and that the very simplicity of his dress was the cause of much ridicule, the disadvantages he laboured under at the French Court make his subsequent achievements as a diplomatist appear all the more creditable to himself, the cause he advocated, and the country he represented. Few men received such honours as were paid to him when his real character was understood. It was fortunate for him and for his country that he was selected for the missions to England and to France, for no one could have better represented the Colonies, and nowhere could he have found a better field for his labours. In London and in Paris must be found, if anywhere at that time, men who could rightly measure his ability and accomplishments. Boston, his native town, and Philadelphia, which was his home in later years, were filled with patriotic citizens eager to do service for their country, but they could not understand the magnitude of Dr. Franklin's undertaking, nor the value of his labours abroad. Then, too, there were few men in America in his day who had any idea of the greatness of his work as a scientist. Even at this late day it is only too evident that Franklin's biographers have failed to grasp the situation in this particular, at least those of them who chronicle his achievements for the information of the general public. In works of a purely scientific character due credit is given the eminent electrician for his experimental work in this line at least and his intelligent observation of electrical phenomena. But it may be said that the scope and quality of his scientific work are not generally understood. As illustrating this point, it is only necessary to refer to any of the popular lives of Franklin. Examine, for instance, that in the 'American Statesman Series,' which is, by the way, one of the most appreciative of these works in other respects, and only occasional allusions will be found to his scientific discoveries and the rank to which he attained in the scientific world. Under the circumstances, then, anything that will awaken an interest in this great American patriot must be welcomed not only by Chicago but by America, and the entire world in fact. We cannot know too much of the character and work of this illustrious philosopher, probably the greatest diplomatist and scientist of his country, and certainly one of the greatest of his age." Our contemporary might, further, have illustrated the reserve for which Franklin, like Napoleon, was so famous and to which the one attributed the success—so far as it went—of his diplomacy, and the other in a measure his success on the field of battle.

CITY AND GUILDS EXAMINATIONS, 1895.

We publish herewith the best set of answers sent us to the questions in the preliminary stage of the City and Guilds examination paper of 1895, in reply to our offer of book prizes in May last. We hold the report of the gentleman who adjudicated on the matter for us, and from it we gather that the answers sent in in this stage were, on the whole, satisfactory. The sketching and diagrams are decidedly better than those sent with the ordinary-grade papers. The remarks of the examiner on the various replies are printed after the questions they refer to. The best set of answers, given below, is by Mr. H. Morgan, of 27, Castle-street, Barry, and we shall have pleasure in forwarding to him books to the value of one guinea as soon as he has made his selection.

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

PRELIMINARY EXAMINATION

1. Give a diagram of the Post Office form of Wheatstone bridge, showing the connections.

Note.—The diagram sent by this candidate, although quite correct, was not suitable for reproduction. The replies to this question show a good general knowledge of the Post Office bridge details.

2. Why are electric bells apt to work badly when coupled in series?

Answer.—Electric bells are apt to work badly in series, because of the irregular breaking of the circuit due to the action of the contact breaker. Single-stroke bells, provided they are similar to each other and that the E.M.F. of the battery is increased in direct proportion to the number of bells in series, will work in series. There is a trembling bell in the market which is intended to work in series, but it does not depend for its action upon a contact breaker, like the ordinary trembling bell. When the armature is attracted, instead of breaking the circuit, it "makes" a contact, which shunts the coils and thus retains the circuit. Though the bell is better for series working, it has not the satisfactory action required in a good ringing bell.

Note.—Only one candidate out of the whole number knew of the simple solution to this difficulty. If two similar bells are connected in series and the contact-breaking arrangements of one are short-circuited so that the magnets only are in circuit, then the contact breaker of the other bell will control the two, and they will work well together. The bells must have similar armatures, hammers, etc., so that the periodic time of the moving parts are practically the same.

3. Where should fuses be placed in an electric lighting installation? And why?

Answer.—Fuses are used in an electric light installation to protect the conductors from overheating. Main fuses should be placed as near the terminals of the source of supply as practicable, so as to leave as short a length as possible being unprotected. Fuses should also be put where a branch is tapped off a pair of mains, and wherever a conductor is reduced in size, because a smaller wire would get overheated by a given current, when a larger wire would carry it without being overheated. Each lamp should also be protected by a fuse, and if there is a switch for each lamp it should be put in the switch because it would be handier to get at, otherwise it should be placed in the ceiling rose. In providing an installation with cut-outs, consideration should be given to the fact that every cut-out is more or less an additional source of breakdown, and also that each one is an additional point to earth. It is not much good using high-class insulated cables when the installation is crowded with switches, cut-outs, and ceiling roses. As a rule, they have large contact surface, and very often inferior to the insulation of the cables. Therefore, wherever practicable, such things should be avoided.

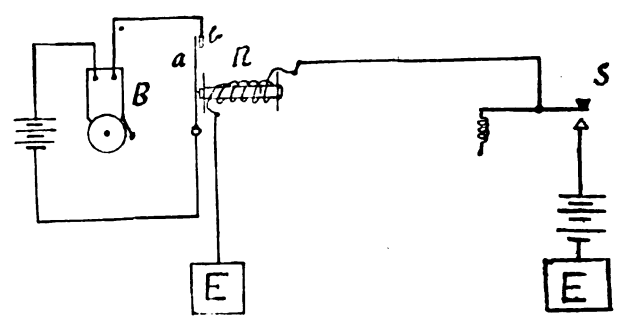
Note.—The last part of this answer is rather contradictory to the first part, but it shows that Mr. Morgan has experienced trouble through the bad insulation resistance of some makes of fuses and switches. These adjuncts to a wiring system must be used, and it only remains to select good makers' wares.

4. A dynamo is 100 yards from a house, the conductor has a resistance of 0 002 ohm per yard, and there are 150 30-watt 100-volt lamps to be fed. What E M F. must the dynamo give?

Answer.—The resistance of 200 yards (main and return) of conductor at ·002 ω per yard = (200 × ·002) = ·4 ω. Total number of watts = 30 W × 150 = 4,500 watts, and since $W \div E = C$ $\therefore \frac{4500\ W}{100\ V} = 45$ amperes. Again, E.M.F. = C × R, $\therefore$ ·4 ω × 45 a = 18 volts, which is the drop in voltage along the conductors—assuming that all the current is taken off at the extreme end. The lamps will require 100 volts at their terminals, and allowing 18 volts for waste in the conductors, therefore the dynamo must give 100 + 18 = 118 volts (E.M.F.).

Note.—Almost all the errors in the answers sent in to this question were due to the candidates taking 100 yards as the total length of the cable, and hence neglecting the return wire.

5. Give a diagram with connections of a relay working an electric bell.



Answer.—The above sketch shows a relay, R, working the electric bell, B. The station, S, might be so far away that the current from its battery is too feeble to ring bell, B. When the current passes through relay it attracts the armature, *a*, and makes contact with terminal, *b*, and completes the local circuit so that the local battery rings the bell.

6. How would you test the insulation in a building you had wired?

Answer. — Assuming the whole was completed with fittings, etc., and lamps removed, I would require an ohmmeter and a small generator. I would turn all switches towards "on" and put all fuse wires in their places.

First Test: Insulation towards Earth.—I would connect one terminal (−) of generator to a good earth, the other (+) to meter, and the remaining terminal of meter to the conductor of main cable the insulation of which is to be tested. Then turn the handle of generator at a moderator speed. The meter would indicate the insulation in megohms. I would then take the other main conductor and treat it similarly. After this I would take both cables together and apply the same test.

Second Test: Insulation between each Conductor (Short circuit). I would remove my earthed connection and connect it to the conductor of one of the main cables and my other connection to the other cable. I would thus obtain the insulation between the two conductors, lead and return. On referring to the regulations according to which the wiring is to be carried out, I would find whether the wiring is satisfactorily done as regards the insulation of it.

Note.—This answer shows a knowledge of what tests are required, and hence in a sense is quite correct. In using an Evershed ohmmeter, however, both terminals of the generator are connected to the ohmmeter.

7. What are transformers, and what are they for?

Answer.—There are two kinds of transformers—first, for alternating currents; and second, for direct current. An

Digitized by Google

alternating current transformer is simply a modification of the induction coil with no contact breaker. It consists of two coils of wire and an iron core; the coils are wound separately, one of a coarser and the other of a finer size, placed side by side, as in Statter's transformer. Sometimes they are both wound one on the other around the iron core, as in the Hedgehog transformer. The coils are well insulated from each other with mica or some other good insulator. A current is supplied to one coil, and the current in the other coil is generated by self-induction, which is a very important part played in alternating currents by the continual reversal of the current. A direct current has no self-induction except on "making" and "breaking" the circuit, hence the necessity for a contact breaker in an induction coil which is supplied with a direct current. A continuous-current transformer is an electromotor with two armatures and two commutators on the same spindle. They may be used to transform a current from a high E.M.F. to a low E.M.F., or from a low to high, the former most often. By their use we are enabled to transmit electrical energy economically over a long distance, because a small current at a high E.M.F. may be carried by a small wire but well insulated, and then be transformed down to a low E.M.F. and large current, as may be required to suit the consumers.

Note.—Most of the replies show a knowledge of the essential parts of an alternating-current transformer, but not more that 25 per cent. contain the ruling principle that the voltage in the two circuits varied directly as the number of turns in each circuit. Unfortunately, a larger number of students state that the E.M.F. varied with the resistance of the circuit. The reply above shows rather a hazy notion of the subject, and the student evidently thinks that the mysterious term "self-induction" will cover the want of accurate knowledge. It is mutual induction, rather than self-induction, that effects the transformation.

8. How many 16-c.p. lamps, taking four watts per candle, can be run off a dynamo giving 7 e.h p. ?

Answer.—7 e.h.p. = 746 × 7 = 5,222 watts; 16-c.p. lamp taking four watts per candle = 64 watts ∴ number of lamps that could be run off dynamo = 5,222 ÷ 64 = 81 lamps, and we have a surplus of 38 W, which would not be sufficient for one more lamp. No consideration is made for loss in cables.

9. Why can a leaden bullet be fired further than a piece of wood of same shape and size?

Answer.—Suppose we drop a piece of lead and a piece of wood of the same size and shape in a vacuum, both would reach the floor the same time precisely. Now, drop both in air, the piece of lead would reach the floor first, because the lead is denser—that is, there is a greater number of particles occupying the same amount of room, and proportionately it receives less obstruction due to the resistance of the air. We have the same amount of rubbing surface in both, but we have more matter in the piece of lead. For the same reason a lead bullet can be fired further than a piece of wood of the same size and shape.

Note.—Some shaky answers have been received to this question. The correct reply is that the energy stored in a moving body is equal to the product of its mass into half of the square of the velocity. Hence, assuming the bullets to start with equal velocity, the lead bullet having more mass will have more stored energy and go further.

10. If a man supports a weight of 10lb for 17 minutes, does he do any work? If so, how much?

Answer.—He does no work. He simply supports the weight against the force of gravity. We are not given that the man lifts the weight any distance. This sort of work is measured in foot pounds (ft.-lbs.). The amount of work done is directly as the weight and distance, and the power of doing work directly as the weight, distance, and time in seconds.

11. What are watt, pound, horse-power, volt, ampere, and ohm? Give any relations you can between them.

Answer.—Watt is the unit used for measuring the rate of doing work in an electrical circuit and is the same as horse-power in mechanical work: 1 watt = 1 volt × 1 ampere; $W = C \times E$; and since (by Ohm's law) $E = C \times R$, $\therefore W = C^2 \times R$. One watt acting for one second does one joule of work. That is, a current at the rate of one ampere along a wire whose difference of potential at its ends is one volt, or whose resistance is one ohm in one second, does one joule of work.

Pound is a factor of the unit used in mechanical work for expressing work done in foot-pounds. One pound raised 33,000ft. = 33,000 foot-pounds of work; or 33,000lb. raised one foot also = 33,000 foot-pounds. One pound is analogous to R, E, or C in electrical work as being a factor of the unit.

Horse-power is the unit used for measuring the power of doing work: 33,000 foot-pounds of work per minute = 1 h.p.; and 1 h.p. = 746 watts = 1 e.h.p.

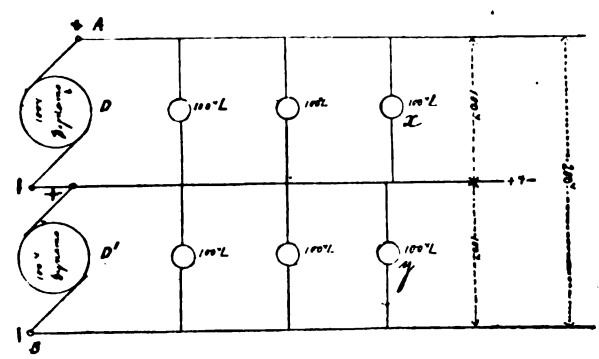
Volt is the practical unit of electrical pressure, and is equal to 10^8 in terms of the C.G.S. system of units, and is that pressure if steadily applied to a conductor whose resistance is one ohm, and will produce a current of one ampere.

Ampere is the unit rate of flow of current along a conductor, and is that rate which caused to flow through a solution of silver nitrate will deposit silver at the rate of ·001118 of a gramme per second. According to the C.G.S. system, it is equal to $\frac{1}{10}$.

Ohm is the practical unit of electrical resistance, and is equal to the resistance offered to a column of mercury 106·3 centimetres long and one square millimetre in sectional area at a temperature of melting ice, and is equal to 10^9 in terms of the C.G.S. system.

12. What is the three-wire system, and what is the good of it?

Answer.—The three-wire system is a system in which two dynamos are connected together in series, as shown in the figure. The two outer leads are connected to the outer



terminals of the dynamos, and a central wire is connected to the wire which connects both dynamos together. When the six lamps are burning, all the current would leave at the terminal A, and would return at B. Supposing lamp *x* went out, then the central wire would act as a + lead for dynamo, D, feeding one lamp on the other side. Again, supposing lamp *y* went out, the central wire would act as a − lead for dynamo, D, feeding the odd lamp on the other side. Thus it will be seen that when the number of lamps are equal on both sides, the central wire carries no current. It simply acts as a balancing wire if the number of lights be unequal on either side. There is 200 volts pressure between the outer leads, and between the central and either of the outer leads there is only 100 volts. It is used for street mains for lighting densely populated areas where the supply station can be placed in the middle. It may also be used for wiring large buildings. There is a great saving of copper with this system—the outer leads only carrying half the current that would be required for the same number of lamps on the ordinary parallel system, whilst the central wire, which acts only as a balancing wire, need not be so large a size as either of the outer leads. The chief object of this system is the wide distribution, and at the same time saving a great amount of copper. It has also the advantage of being a low-tension system. Although we have a pressure of 200 volts between the outer conductors, only 100 volts need be taken into the consumer's premises.

Digitized by Google

13. Two lamps of 100 and 150 ohms each, when running, are put in parallel with each other, and the pair is put in series with a lamp of 100 ohms. What E.M.F. will be needed on the system in order that it may consume 250 watts?

Answer.—The joint resistance of the two lamps in parallel is $\frac{100 \times 150}{100+250} = \frac{15{,}000}{250} = \frac{300}{5} = 60\,\omega$ When the other lamp is put in series we get a total resistance of $(60\,\omega + 100\,\omega)$ $160\,\omega$. Now, $W = C \times E$; and since (by Ohm's law) $E = C \times R$, $\therefore W = C^2 \times R$, and $\therefore C^2 = W \div R$; $\therefore$ the square of the current equals $\frac{250}{160} = 1{\cdot}56$. $\sqrt{1{\cdot}56} = 1{\cdot}24$ amperes (nearly).

Again, since $E = C \times R$, $\therefore 160\,\omega \times 1{\cdot}24\,a = 198{\cdot}4$ volts, which would be the E.M.F. required. These figures are a little too low.

Note.—The only error here is in taking the square root $\sqrt{1{\cdot}56} = 1{\cdot}25$, hence $E = 160 \times 1{\cdot}25 = 200$.

14. What is generally the difference between voltmeters and ampere-meters of the same type?

Answer.—The general difference between a voltmeter and an ampere-meter of the same type is a voltmeter is wound with "many" turns of fine wire, and is connected as a shunt across the circuit, and indicates the difference of potential between the two points of the circuit where it is connected in. An ampere-meter is connected in series in the circuit, so as to take all the current passing, and indicates the number of amperes passing; it is wound with a "few" turns of thick wire.

15. Why does an electromagnet pull so much less if you take out the iron core and replace it with a brass one?

Answer.—Because brass is not a magnetic body. It has no conductance for lines of force or magnetic flux. Soft annealed iron is the best magnetic body. When it is used as a core for an electromagnet it concentrates the lines of force—brings them more central or more together in the centre—and very much increases the pull of the electromagnet. Brass does quite the opposite, hence the difference. It is often used as a regulator for induction coils.

Note.—The whole of the answers show a want of knowledge of the magnetic properties of iron. All speak of a concentration of the lines of force as though that was the sole action of the iron core, and neglect the fact that the permeability of the iron increases the total number of lines flowing by some thousandfold at least.

16. Why are glow lamps generally run in parallel and arc lamps in series?

Answer.—Parallel running is more satisfactory for glow lamps than series. It would be practically impossible to run a great number of glow lamps in series. Suppose we had 20 glow lamps in series, and each requiring 100 V, we would an E.M.F. of 2,000 volts, which would be decidedly dangerous for incandescent lighting. Another great nuisance would be to have an automatic cut-out for each lamp. Series running is most satisfactory for arc running. Arc lamps take, as a rule, from 10 to 15 amperes at about 40 or 50 volts. Suppose we had 20 arc lamps parallel requiring 15 amperes each, 20 lamps would take 300 amperes. This number of arc lamps would light a large area or great distance, hence we would require very large conductors to carry this current without suffering a great waste of energy in the conductors.

17. Define the terms: insulation, insulator, battery, switch, condenser, electromotive force, relay, depolariser, vacuum tube, electrode.

Answer.—Insulation is the protecting of conductors from all external substances—the protecting of a conductor, so that no current can leak to earth or other substances.

Insulator is the name given to a substance which is used for protecting conductors, and through which no current will pass. There is no such a thing as a perfect insulator, although we have some very good insulators.

A battery, whether a primary or a secondary, is a source from which we derive electrical energy by the chemical action of liquids and metals.

Switch is an apparatus by which we turn "off" or "on" electrical energy in a circuit, and serves for the same purpose as the "tap" in gas or water.

Condensers are used for storing electrical energy or increasing the capacity of the conductors.

Electromotive force is that force which causes a difference of potential between two points, and a current of electricity flows from the one point to the other when connected together.

Relay is an electromagnet in which is an armature, which, when attracted, completes a local circuit. It is generally used in electric bell circuits.

Depolariser is the substance used in primary batteries for preventing the battery polarising, such as dioxide of manganese, bichromate of potash, chromic acid, etc.

Vacuum tube is a tube of glass from which the air has been partially excluded, and platinum wires are sealed in at each end, in which beautiful effects are produced by means of the secondary current of an induction coil by passing sparks through the tube.

Water may be decomposed by passing a current of electricity through it. The process is called electrolysis, and the tips of the wires which enter the liquid are called the electrodes, whatever substance the conductor may be. One is called the positive electrode and the other the negative electrode.

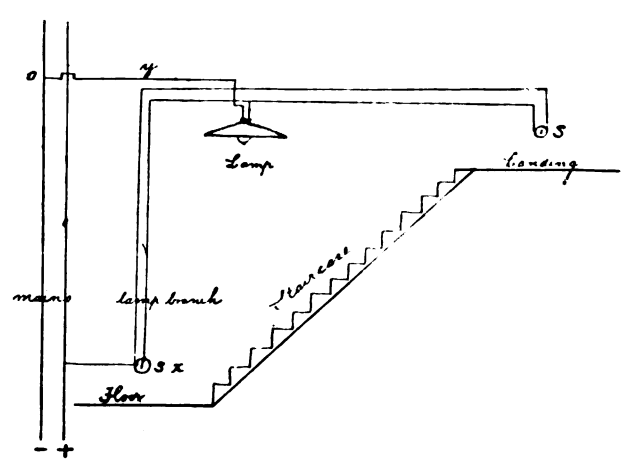
18. What is the white metal used for the tips of the contacts in electric bells? Why is silver not used for this purpose?

Answer.—The white metal used for the tips of the contacts of electric bells is platinum. Silver would be more expensive. There is continual sparking at the contact breaker of an electric bell. The amount of sparking depends on the E.M.F. and the kind of metal. This spark fuses the parts and causes a bad connection. Platinum is only fusible at a very high temperature, and keeps the contact good.

Note.—This answer is wrong. Platinum is used because it does not oxidise.

19. Sketch the arrangement of wires and switches that would enable a staircase lamp to be turned off or turned on from either the foot of the stairs or from the head of the stairs.

Answer.—The sketch shows an arrangement by which a staircase lamp may be switched on or off at the foot or the

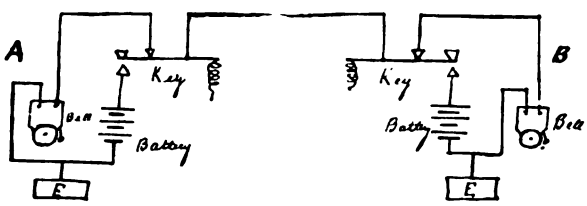


head of the staircase. The casing from x to y of lamp branch may be run on top of the main casing, and would be less conspicuous. I would join the return wire into main at o. I would prefer bringing + wire of the "landing" switch down to the other switch, and connect it into the terminal, so as to avoid cutting the insulation of the mains as much as possible, because every additional joint is a weak point. No cut-outs are shown; I think a fuse in the ceiling rose would be sufficient. The switches may also be provided with a fuse wire each, but I would not consider it necessary for reasons given in *Answer 3*.

Digitized by Google

Note.—No one has given a fully correct answer to this question. The diagram shows a method of switching the lamp on from either place, but it must then be switched off from the same place. To get the correct arrangements, the switches must be of the two-way type, and the wire from the positive wire and the positive lead to the lamp connected to the two handles respectively. The two wires shown between the two switches will then be connected to the two contacts in each switch; then they can be switched on at one place and off at the other.

20. There is an electric bell at A and another at B, with a single line of wire between them. Show by sketches what arrangement of cells and switches are required that a person at either end can call up on the other bell without ringing that at his own end.



Answer.—The above sketch shows how the man at the point A may ring B bell without ringing his own bell, and also the man at B can ring A bell without ringing his own. There is only one line wire, and the earth is used for a return.

THE LECLANCHE PRIMARY CELL AND ITS MODIFICATIONS.

BY J. WARREN.

The earliest and best known form of Leclanché cell consists, as all electricians know, of an outer glass containing vessel, square in form, and having a spout-shaped recess in one corner for the reception of the zinc or negative element, which latter is cast in the form of a rod, and has a stout piece of tinned and braided copper wire cast into its upper end to form a terminal or means of connection to the external circuit.

The carbon or positive element takes the form of a plate of gas-retort or specially-prepared carbon surrounded by granules composed of black oxide of manganese and coke which have been subjected to a heating process, under which they combine in a mechanical way, and are then broken up into small pieces of the required size.

The whole mass, with the carbon plate placed vertically in the centre, is packed in a circular porous pot, and sealed to a depth of about ½in. from the top with pitch, two small pieces of glass or ebonite tubing being introduced as vents for the admission of air or the escape of any gases which might be generated from impurities in the carbon. In some forms of the cell the carbon plate is perforated by two holes, about 1in. apart at its upper end, and a lead cap with a brass terminal screw and nut is cast on, the end of the carbon having first been immersed in hot melted paraffin wax, to guard against creeping of the electrolytic solution. The lead is cast all round the head of the carbon, and fills the two holes provided for the purpose, thus mechanically fixing itself against being pulled off by accident.

The drawback to this form of terminal cap lies in the fact that after a time, however well it may have been guarded against, the sal-ammoniac in the cell will creep up between the inner surface of the lead cap and the carbon and form a white deposit of chloride of lead on the former, completely destroying the metallic contact, and thus greatly increasing the resistance of the cell. It is advisable, therefore, to dispense with the lead cap and bring the plain end of the carbon up about ½in. above the surface of the pitch, attaching the wire to it by means of a clamp terminal, which can at regular intervals be removed and its surfaces of contact cleaned.

It is usual to immerse the top of the rim of the porous pot to a depth of about 1in. in melted paraffin wax before using, keeping it there for a few minutes to allow the melted wax to fill the pores. This precaution will also assist in preventing creeping.

In cases where the cell is to be used in conjunction with many others for the production of a high potential or testing purposes, etc., it is generally completely sealed, the charged porous pot and zinc rod being first placed in position in the outer jar; the latter is then filled with dry sand to within ½in. of the top, two glass tubes are placed in position, as in the case of the porous pot, and melted pitch or marine glue is then poured in until it is level with the top of the cell. When it has set, the sand is poured out through one of the tubes and the saturated solution of sal-ammoniac added until the outer jar is quite full. It is then allowed to stand for about 24 hours to give the solution time to percolate through into the porous pot. The level of the solution in the outer cell will then be found to have fallen to about three-quarters of the depth of the jar, or a little below the neck, and a small quantity of sal-ammoniac may be added to keep the solution saturated. The amount of undissolved salt should not, however, exceed ½in. in depth at the bottom of the jar. The ventholes may now be temporarily closed by small corks, and the cell inverted and immersed to a depth of from 1in. to 1½in. in a vessel containing melted paraffin wax. The cell being again placed in an upright position, and the vents unplugged, it is now in a fit condition to be put to work, and should last for months without attention.

Another very convenient form of this element is that known as the "agglomerate" Leclanché cell. In this type the crushed coke and dioxide of manganese are mixed with a certain amount of tar, and compressed into rectangular blocks, which are then baked. One of these blocks is placed on each side of the carbon plate, and the whole is secured by two indiarubber bands provided with a perforated lug at one corner for the reception of the zinc rod. The porous pot is thus dispensed with and the internal resistance of the cell diminished.

Several of the most well-known forms of so-called "dry" batteries being modifications of the Leclanché element, I will here give a description of two of them.

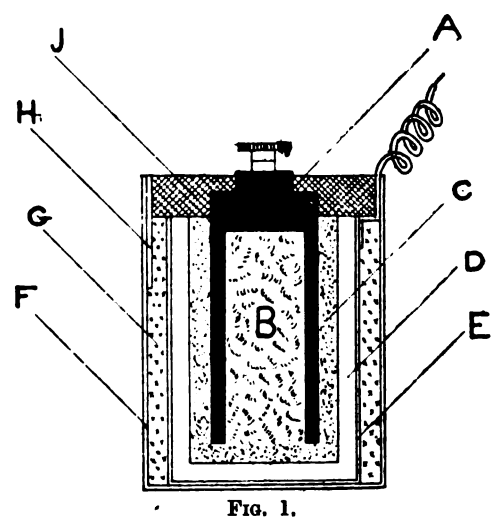


FIG. 1.

To begin with, the Hellesen dry cell, supplied by Messrs. Siemens Bros., of Woolwich, has a positive carbon electrode, A (Fig. 1), in the form of an inverted cylinder, the interior being filled with silicate cotton, B. Round the outside of the carbon cylinder is placed a paste, C, made up as follows:

	Per cent.
Manganese dioxide	25·54
Carbon	16 02
Silicate	12·76
Magnesia	12 88
Lime	0·96
Peroxide of iron	3·46
Moisture and ingredients not determined	28·38

Next comes a layer of white paste, D, of which the following is an analysis:

	Per cent.
Lime	26·18
Oxide of zinc	6·00
Magnesia	0·51
Ammonia	2 49
Water and binding material	64·82

Digitized by Google

This forms a lining to the zinc cylinder, E, which is also the negative electrode. The whole is placed in a mill-board case, F, the space between the latter and the zinc being filled with sawdust packing, G. A stout wire is soldered to the zinc cylinder to form a terminal, and the carbon is also provided with a brass terminal screw and nut. A waste tube, H, is provided, and the whole is sealed with pitch, J.

The E.C.C. dry cell, which I shall next describe, is somewhat similar both in construction and the composition of the exciting pastes. It consists (Fig. 2) of a carbon plate, A, embedded in a black paste, B, made up as follows :

	Per cent.
Manganese dioxide	7·57
Carbon	47·26
Magnesia	7·20
Lime	1·40
Peroxide of iron	2·12
Ammonia	12 78
Water	9·77
Ingredients not determined	11·90

Next comes the white paste, C, as follows :

Lime	20 89
Ammonia	20·29
Chloride	6·31
Water and binding material	52 51

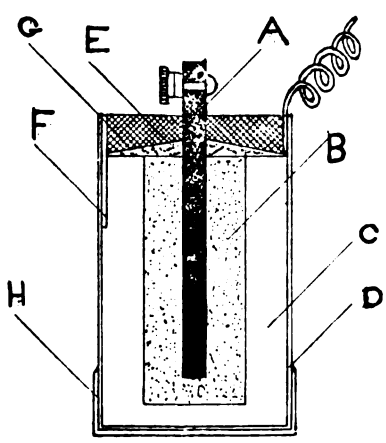

FIG. 2.

Then comes the zinc containing vessel, D, to which is soldered the usual wire connection. A thin layer of silicate cotton, E, is placed on the top, a waste-pipe, F, is provided, and the whole is then sealed, as before, with pitch, G. A terminal bolt and nut is introduced into the head of the carbon, and with the exception of an insulating base, H, the cell is complete.

It will be seen from these descriptions that the cells, though dry, contain a certain amount of liquid, which is, however, dissipated in the form of paste, thus rendering them for all practical purposes very convenient, as they can be placed in any position, and are portable. As a matter of fact, a true dry cell is an impossibility, as to produce a current in a primary battery there must be chemical reaction, and this is impossible in the absence of moisture.

The great drawback to this type of cell lies in the fact that they polarise very rapidly, and having no free liquid in their composition are unable to recoup themselves for some time. This renders them unsuitable for a current discharge of any intensity.

MUNICIPAL TELEPHONY.*

BY A. R. BENNETT.

The members of the Northern Society of Electrical Engineers have frequently had before them municipal projects for the supply of electric light and power, and the discussions which have taken place on these subjects have been of great interest and practical utility, but so far the society has not taken cognisance of telephones nor of telephone questions. I have therefore chosen telephones as the subject of the paper which I have been invited to contribute, particularly in their relation to municipal authorities.

In this country we have had no actual experience of municipal control of telephone systems, although Glasgow and several of the other Scottish towns are desirous of making a move in that direction ; but abroad things have been different, especially in Norway, where in one town of importance the telephone system has been owned and managed for the last six years exclusively by the Town Council ; while in Christiania the municipality has contributed to the capital of the local telephone company, and, being represented on its board by three town councillors, exerts a powerful influence on its management. These experiments have been so decisively successful that municipalities in other countries are taking steps to imitate them. Thus we find that the Town Council of Rotterdam is actually engaged in the construction of a telephone system of its own. The Rotterdam municipal exchange is to be opened in October, 1896 ; it is to be metallic circuit throughout, and the annual subscription is to be £6. 5s. 5d. for distances of five kilometres, or three English miles. The Town Council of Amsterdam has also resolved to build a new exchange, but neither the date of opening nor the subscription has yet been fixed. These facts have an important bearing on the present position of telephony in the United Kingdom. Our telephones are now controlled by two bodies only—the Post Office and the National Telephone Company. The exchanges possessed by the Post Office, with the one exception of Newcastle-on-Tyne, where there are some 600 subscribers, are quite insignificant, the Post Office subscribers in the United Kingdom not exceeding some 12 or 13 hundred in number. The Post Office exchanges, moreover, show no tendency to develop, many of them quite the contrary. Even Newcastle-on-Tyne has remained practically stationary for years, for the Post Office exchange in that town numbered 600 subscribers seven or eight years ago. The result is that the National Telephone Company is virtually invested with a monopoly, which, according to evidence given before the late Select Committee on the telephone service—evidence which is re-echoed from all parts of the United Kingdom—the company does not employ in a manner calculated to satisfy the reasonable requirements of the public. Independent companies have endeavoured from time to time to compete with the National Telephone Company, but always unsuccessfully, because this powerful corporation has invariably bought up its opponent regardless of cost—tactics which have been rendered successful solely by the support which it receives from the Post Office.

No person or company may construct telephone exchanges in this country without a license from the Post Office, and such licences have for several years past been withheld. The telephone patents under which the National Telephone Company for many years preserved its monopoly expired in 1891, and the public then looked forward, as a perusal of the Press articles of the period clearly shows, as it had a right to do, to competition as a means of bringing about a reduction of the heavy charges to which it was subjected, and of improving a service which was admitted by the company's own directors to be atrociously bad. But no sooner had the patents expired and the grasp acquired by the company on the country by their means loosened than the Post Office reinvested the company in its monopoly by refusing to grant any more licenses. The patent laws for 14 years enabled the company to defy all competitors, and when these laws ceased to be operative the Post Office stepped in and used the power which had been conferred on it by Parliament to confirm and extend the monopoly. The consequence is that telephonic charges in the United Kingdom are greatly in excess of those which prevail in most other countries, and approximate to double the figure at which they would stand if the earning of a fair dividend on the amount of capital invested in the construction of the exchanges were the accepted principle of the company's action. Unfortunately, even by the admission of the company itself, its capital consists to a large extent of "water" on which dividends have to be paid ; consequently the charges levied on the subscribers must be higher than would be the case if companies or other bodies, unhampered by surplus capital, were permitted to take a share in the supply of British exchange telephones. Before the late Select Committee the National Company admitted that its capital was watered to the extent of £1,292,000. This amount, in the opinion of some who have studied the subject, should be at least doubled ; but, accepting the company's own figures for the nonce, and likewise the statement that the company's lines numbered 73,338, it appears that £17. 11s. of "water" exists for each line owned by the National Company. Well, the late Dundee and District Telephone Company's lines cost £15 each ; the late Mutual Telephone Company's (double lines), £16. 16s. each ; the Christiania Telephone Company's, £12 each ; the Trondhjem Municipality's, £10. 2s. 6d. each. It is plain, therefore, on the National Company's own showing, that the "water" which exists for each line erected by the company exceeds the proper cost of the line, and that each line must stand in the company's books at much more than twice its actual cost. Such a state of things cannot exist without inflict-

* Paper read before the Northern Society of Electrical Engineers, November 11, 1895.

Digitized by Google

ing grave injury on the telephone subscriber as an individual, and on the commercial interests of the country as a whole, yet it is a state of things that the late Government, through its Postmaster-General, did its best to justify, support, and perpetuate.

Unquestionably, to whatever cause the fact may be ascribed, the development of telephony in the United Kingdom has lagged behind that attained in many other countries. In a paper which I contributed to the British Association at its recent Ipswich meeting, I gave statistics which showed that the United Kingdom, the greatest home of industry in the world, ranked only tenth in the point of telephonic development amongst the European nations, and I sought to account for this unpleasant fact by comparing the conditions which exist here with those which have enabled nine other European countries to outstrip us. This state of things is a serious one for the British man of commerce. In Germany, Belgium, Norway, Sweden, Denmark, and other countries, we find a large proportion of the towns connected by trunk lines, so that the subscribers may call up their correspondents in all parts of the country. In many cases the trunk lines have now passed the boundaries of the different countries, and the merchants of several of the capitals and of the chief ports and centres of industry in the various states may communicate telephonically. I am, of course, aware that trunk lines exist in this country, and that communication has been established between London and Paris, but there is this important difference. On the Continent the charges made for the use of the trunk lines are extremely reasonable: thus, in Germany one can telephone all over the country for the sum of 1s. per three minutes; and even lower rates prevail in other countries. In the United Kingdom the charges are so heavy (and after the 1st of January next, when the Post Office will assume control of the trunk lines now worked by the National Telephone Company, they will be still further, in many cases, increased) that trunk line communication remains a luxury. No doubt the Post Office could point to a considerable telephonic traffic between London and Paris, and perhaps between London and Manchester, Liverpool and Glasgow. But an analysis of this traffic would probably show that the lines are not used as a rule by the commercial or manufacturing communities, but by stockbrokers for the purpose of buying and selling stocks. Communication between London and Paris is almost exclusively to this end, and, I believe, the same applies to the use which is made of the new trunk line between London and Glasgow. The fact is explained by the high rates charged, which stockbrokers can afford to pay and others cannot. Thus the curious circumstance is brought out that the public money voted by Parliament to the Post Office for the development of telephonic communication, is being devoted mainly to the benefit of one class, and that a class not generally esteemed the most reputable of the community.

Having briefly summarised the present position of telephones in the United Kingdom, I will ask the members of this society to accompany me in spirit to Norway and there ascertain what has been done by municipalities with the object of bringing home the telephone to every business man, and of allowing those who desire it the luxury of telephonic communication in their private houses. It may be remembered that the late Postmaster-General stated in the House of Commons that telephones in this country must always remain a facility to be enjoyed by the rich, and that even if by low rates a very large circle of subscribers could be obtained, the technical and engineering obstacles in the way of connecting them to an effective exchange were insuperable. Of course, no practical telephone man believes that, even in this country; and abroad the statement of Mr. Arnold Morley has created much amusement, for foreigners have in their own cities, and even in their own villages, proofs before their eyes that the statement is inaccurate.

I recently made a minute inspection of the telephone system of Trondhjem, which is the third town of Norway, and possesses about 30,000 inhabitants. The original telephone exchange was commenced in 1882 by a Mr. L. Spörck, who had obtained a concession from the Town Council. Mr. Spörck secured a considerable number of subscribers, which was not surprising, seeing that his charges amounted only to £2. 10s. per annum for a place of business and £1. 5s. per annum for a private house, rates which applied to distances not to exceed about an English mile. But the service given was not entirely satisfactory, and in 1889 the Town Council determined to purchase Mr. Spörck's system and thereafter manage the telephone business itself. Mr. Spörck having been paid the sum of £1,833 for all his rights, the Town Council proceeded to reconstruct his system in the most substantial and modern manner, a proceeding which, no doubt, provided a good telephone exchange, but which burdened the town with nearly £2,000 of superfluous capital at the start, inasmuch as the value of Spörck's material when taken down was so small that the purchase-money paid was not represented by any valuable asset. The capital expenditure, including the aforesaid purchase-money, now stands at £7,979, with which sum 780 exchanges and eight private lines have been constructed. The total number of lines being thus 788, it follows that each line has cost the town on an average £10. 2s. 6d. The population of the town being 30,000, there is one exchange telephone to each 38 inhabitants. In the United Kingdom the proportion is one in 636. The rates fixed by the Town Council were rather higher than those of Mr. Spörck, but are not, nevertheless, such as would be considered at all excessive in this country. They are as follows (per annum):

For a telephone exchange line connecting a place of business not exceeding 1½ kilometres (about one mile) from the central station	£3	6	7½
For a second business connection for the same person or firm	2	13	3
For a private house, not exceeding 1½ kilometres from the central station	1	13	4

Should lines exceed in length 1½ kilometres, these charges are increased by 5s. 6d. per annum for each 100 metres in excess. These charges include all payments. The Town Council supplies all the lines and instruments and maintains them. It is necessary to take particular note of this fact, because in some places in Norway and other countries subscribers buy their own instruments and pay the cost of their lines, circumstances which have sometimes been put forward as applying universally to all cheap Continental rates; but they are the exception, not the rule. At the middle of last October the value of the subscriptions on the books amounted to 38,300 kroner; and the number of exchange telephones being 780 the average revenue per telephone was 49·1 kroner, or £2. 14s. 4d. per annum.

The Town Council of Trondhjem consists of a burgomaster, 12 aldermen, and 36 councillors. The telephone business is managed by a telephone committee composed of two of the aldermen, one member of the committee being always a practical engineer. The committeemen retain their positions for four years, and are thus able to obtain a thorough grasp of the business. Acting under the committee is a manager and engineer who has qualified in the latter capacity in the Trondhjem Technical School, and acquired considerable telephonic experience in other Norwegian towns.

The capital is provided out of the rates, but interest at the rate of 4½ per cent. per annum is charged against the telephone system, so that the ratepayers not only lose nothing by the concern, but even make a good profit. It should here be mentioned that the tariff given above is subject to alteration by the Town Council if such a course should appear desirable, so that the income may be adjusted to the expenditure, and any increase of cost in working thrown upon the telephone subscribers, and not upon the ratepayers. It is, however, satisfactory to note that the tariff has sufficed hitherto not only to cover the working expenses, to provide interest on the capital, to create a reserve fund of 5 per cent. per annum on the capital expended, to ensure all the employés against death, accident, and sickness, but to leave a small surplus every year.

One of the many noticeable differences between Government, private, and municipal control of telephones is the fact that the German and other Continental Governments, like our own Post Office, render no accounts that outsiders can understand. The figures published do not distinguish between the telegraph and the telephone. Details of cost, salaries, etc., are carefully avoided, so that criticism is disarmed for want of material. Quite different is the procedure of the Continental telephone companies, whose accounts are models of precision and present all the necessary facts, together with the results obtained, in a plain and business-like manner. The Municipality of Trondhjem imitates this praiseworthy example, and, having nothing to conceal, sees no harm in taking the public entirely into its confidence. I am therefore able to place very exact details of the cost and results of the Trondhjem system before the society. Every year a budget or estimate of receipts and expenses for the ensuing year is prepared for, and sanctioned by, the Town Council. The following return shows in the first column the budget for 1894, and in the second column the results actually obtained for that year. The third column shows the items on which the budget estimate was exceeded, and the fourth those which failed to come up to the estimated figures.

COMPARISON OF THE BUDGET FOR 1894 WITH THE RESULTS ACTUALLY OBTAINED.—One krone = 1s. 1¼d.; 18 kroner = £1.

Receipts

—	Budget estimate.	Actual accounts	Excess over budget.	Under budget.
	Kr.	Kr.	Kr.	Kr.
Subscriptions received	34,307 00	34,320·51	14 51	—
Trunk-line fees	—	153 65	153·65	—
Sundry receipts	593 00	1,032 10	439·10	—

It will be seen that a profit of 2,700 kroner, or £150, was anticipated in the budget, but when in Trondhjem last month (October) I was assured that the estimate of receipts both for local subscriptions and trunk-line fees had been already more than realised. The estimate provides for an increase of only 45 subscribers for the whole year, whereas in October 84 had already been obtained, and the revenue stood at 38,300 kroner instead of the estimated 36,900. Instead of new orders ceasing with the growth of the exchange, as it was feared by some that they would, they are coming in faster than ever, and it is in contemplation to instal next year a multiple switchboard of the most modern type for the purpose of providing adequately for future business.

Having told you the terms on which telephony is supplied in Trondhjem, I shall now proceed to let you know what the subscribers obtain for their money. The subscribers are connected to the exchange chiefly by single aerial wires of phosphor bronze, but some have copper wires carried in suspended cables. Communication is obtainable at present only between the hours of 8 a.m. and 10 p.m., Sundays included, but the early establishment of an all-night service is contemplated. There are 11 towns in the neighbourhood of Trondhjem where exchanges exist, and with which trunk lines afford communication. These outlying exchanges are owned by local companies, not by the Trondhjem Municipality. The charge for speaking to them is 2d. for five minutes for subscribers, and 3½d. for non-subscribers. The most distant of these are: Hovin, 28½ miles; Stören, 31; Gosbak, 34¾; Svorkmo, 47½. It is thus possible to speak for five minutes over a trunk line 47½ miles long for 2d.

The Norwegian Post Office is also constructing for the use of the Trondhjem subscribers, and has nearly finished, two metallic circuit trunk lines through Levanger (43½ miles) to Stenkjær (68½ miles) in the North, which it is intended to subsequently extend to Namsos (105¾ miles). These lines are of 3mm. silicum bronze. The trunk line to Christiania (349¼ miles) is also to be commenced in 1896. The map before you will give you an idea of the actual telephonic network in communication with Trondhjem, as well as of the contemplated trunks. There is not at present any communication between the telephone system and the telegraph office, so that the subscribers are not able to forward telegrams from their own houses; but this defect is also to be remedied very shortly, the Town Council having promised to connect with the telegraph office whenever the Government desire it. Subscriptions are payable half-yearly in advance. The subscriber is only required to sign an agreement for six months, and can discontinue his line at any time by giving notice of that duration. When the subscriber shifts his office or his house, the cost of the labour of reconnecting him at the new place is charged, but the necessary material is provided free. The police and fire stations are connected, and special facilities are afforded for the calling of cabs, etc. The fire system of Trondhjem is very complete, there being no less than 28 electric fire-alarm stations scattered through the town and suburbs, worked by a central battery at the fire office. This fire-alarm system is managed by the telephone exchange, and the cost of maintaining it is borne by the telephonic budget, so that the telephone subscribers really support not only the telephonic exchange, but also the fire-alarm system. There are 10 public telephone stations in convenient localities, whence subscribers and non-subscribers can obtain communication with Trondhjem and the towns connected by trunk lines. Six of these public stations are situated in kiosks, primarily intended for the sale of newspapers, placed in the streets. The charge is 1½d. per five minutes for local and 3½d. for trunk talks. The fact that they are public telephone stations is indicated by the two telephones suspended from the dragon mouths on the roof. Why similar conveniences should not be provided at busy points in Manchester and other English towns is a problem which I will leave to the members of this society to solve—if they can.

It has sometimes been said in extenuation of the high charges in force in this country that the low rates on the Continent are possible because the construction work is badly done; that cheap material is used, and no efficient technical supervision provided. I have already had occasion to emphatically disagree with these assertions, as in my book on "The Telephone System of the Continent of Europe," I give several instances in which the cheapest rates coincide with the best workmanship and most modern material and apparatus. Trondhjem is another case of this nature. The rates are very low, as we have seen, and yet the workmanship and material is extremely good. The wire used is of phosphor bronze, 1·25mm. in diameter, being the same as generally used by the National Telephone Company in this country. Not only is the wire of the same nature and of the same gauge, but it is procured from the same makers, Messrs. Felten and Guilleaume, of Mulheim-on-the-Rhine. As Trondhjem is about 830 miles north of London, it follows that the freight incurred on the wire is very considerably in excess of that paid in England, so that the low rates in Trondhjem are certainly not attributable to the excessive cheapness of the wire used. This wire is supported principally upon iron structures, most of which are fixed on the house-tops, although some, as will be seen from the figures, are planted in the ground.

The subscribers are supplied with the beautiful instruments manufactured by the Norske Elektrisk Bureau of Christiania, a specimen of which is now before you. These cost £2. 12s. 2d. each, delivered free in Trondhjem, in lots of not less than 100, exclusive of battery. Such subscribers who desire it are supplied with instruments made by Messrs. L. M. Ericsson and Co., of Stockholm, the price of which is higher—viz., £2. 17s. 8d.—in lots of 100, delivered in Trondhjem. The Trondhjem instruments, therefore, cost more than those supplied to telephone subscribers in this country, while their workmanship is superior. The insulators used for supporting the wires are made at Porsgrund, in Norway, and cost 2d. each without the bolt. They are of a double-shed pattern. On some of the more crowded routes the subscribers' wires are led in suspended cables. Two of these cables contain 50 wires each, and are of the Pattinson type—that is to say, the wires are insulated with dessicated cotton saturated in paraffin wax, and protected by a heavy leaden tube. Others contain 25 wires, and are insulated with indiarubber protected by lead in the same way. These last cables were supplied by Felten and Guilleaume.

The working staff consists of five linemen, who work from 7 a.m. till 6 p.m., with one hour off for dinner. Their pay is £43. 6s. 8d. per annum, with an extra allowance of £6. 13s. 3d. to the oldest man, who acts as foreman. The Town Council

Digitized by Google

insures each man for £111 against death, and also for allowances in case of accident or sickness, the premium paid being 9s. 11½d. for each £55 of wages. Although the pay of these men may appear low, it is extremely doubtful whether that of the telephone linemen in any town of equal size (30,000 inhabitants) in the United Kingdom averages so much. The operating staff consists of young ladies, eight of whom, with the superintendent, are on duty at one time. At present their duties average a little less than 9½ hours per weekday, but as this is considered too long three new operators are about to be appointed. Their pay at present varies from £2. 4s. 5d. to £2, 15s. 5½d. per month, but the scale of wages sanctioned by the Town Council provides for an ultimate increase to £3. 6s. 7½d. per month. The pay of the lady superintendent is at present £40 per annum. In addition, there is a staff of reserve operators, consisting of young girls who have learnt the business, but who, pending vacancies on the permanent staff, are only called in on emergencies. They receive a small retaining fee, and are paid for work actually done at the rate of £2. 4s. 5d. per month. As each subscriber asks on the average from eight to nine connections per day, the girls have plenty to do during the busy hours. Each girl has 14 days' holiday per annum on full pay and is insured against sickness. It will be seen that, whatever may be thought of the workmen's wages, the lady operators receive considerably more than their English sisters.

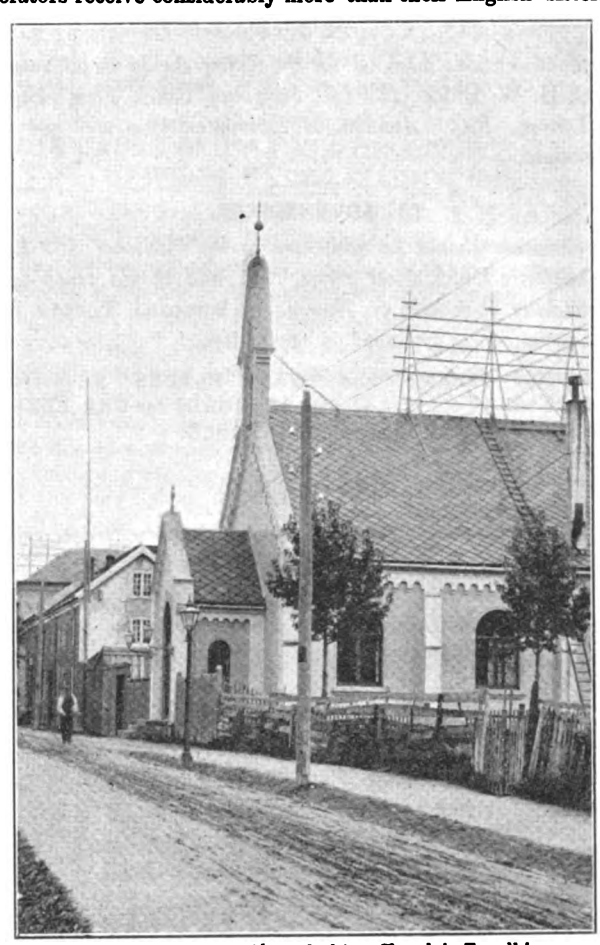
Iron Lattice Poles in Sondre Gade, Trondhjem.



View of 100-wire Standard attached to a Church in Trondhjem.

It is certainly a strange comment on the talk we have heard of the greater cost of telephonic work in this country to find that girl operators in Trondhjem are paid better than those of London, Manchester, or Glasgow.

THE BRITISH ELECTRIC TRACTION (PIONEER) COMPANY.

Of late years the launching of electrical companies has been an operation of infrequent occurrence. A feeling has been growing up which promises rapid development in the way of traction in the near future, and if nothing more pointed to such a conclusion the floating of the above-named company would be an indication of the fact. The Electric and General Company, under whose ægis this pioneer company is brought out, is usually considered to be well in the know, and to be pretty certain of success before it puts its hand to the plough. The mere fact, then, that a pioneer company is projected means that its projectors see the way to do business. Before touching upon one or two of the problems presented by electric traction, and especially in its commercial aspect, it will be well to call attention to the fact that though the British Electric Traction Company is termed a pioneer company, its articles of association are broad enough to cover any expansion its directors may deem wise to undertake. So far as the prospectus is concerned, it says little, but infers much. It promises nothing; and yet we should imagine the company will become a handsome profit-earning concern, a prediction the more easy to prophesy when we consider by whom it is floated. "The profits of this pioneer company," says the prospectus, "will depend upon the successful issue of the capital of the larger company." Depend upon it, promoters would not go to the trouble of floating a pioneer company which is valueless without the "further step" as a dividend-paying concern, unless they saw the possibility of that further step being shortly taken.

Let us consider the present position of matters with regard to electric traction here. For years we have been urging it on the grounds of sentimentality and economy. The first of these does not count in business, but it has a marketable value when combined with the latter. We have always held that electric traction was economical, and have supported our views from time to time by facts and figures culled from practice. Unfortunately, the most successful practice in this direction has been in America, and causes existed there which made electric traction a more profitable undertaking than seemed to be possible here. Various small attempts have been made in Great Britain to introduce electric traction, but in almost every case the attempt has afforded no real criterion as to the true value of the system. In one place it serves for merely excursion traffic, in another its termini ended nowhere in particular, in another it was fettered by too great initial expense; in almost every case, indeed, the venture was something of an experimental one, and not such as would stand the best chance of paying its own way. The reason of all this is simple. The country was pretty well provided with tramways of one kind or another, few of which pay, most of which are, to say the least of it, injudiciously managed, none of which had any capital unexpended. Hence, even experimental lines could not be made under the best conditions. People are beginning to realise this, and to ask for something that shall be really on

Digitized by Google

a practical commercial basis. Bristol and Dublin may perhaps serve in this direction. This is not enough. The existing tramways are mostly of a dead-and-alive character—dead as regards energy, as regards service, as regards accommodation; but unfortunately so far alive that they linger on to be a by-word and reproach to everybody concerned with them. Of course, we must admit that as there is no rule without exception, so a sweeping condemnation of this kind cannot be made to include every line. A few are really well managed—but a few is all we can admit to this distinction. What is wanted, and badly wanted, is to replace these moribund concerns by lines on which the service is frequent, where time is punctually kept, and where clean and commodious cars are provided. A proposition not understood by the present tramway management, is that the service and accommodation make the traffic, and not that the traffic warrants such-and-such a service. Our railways have found out this secret to success. The results are seen everywhere. The line that gives the best service is always the line which secures the greatest traffic. The business of to-day demands celerity, and the business of to-day will support celerity. The crawl to the South means a decided disinclination to travel in that direction, while the race to the North means that folks avail themselves of the facilities offered. What holds good on our railways and upon our ocean lines holds good for tramways, although the fact has not yet percolated down to the mediocre intelligences that seem to govern and paralyse most of the tramway lines. Is it possible with electric traction to give what is so urgently needed? If so, it is sure of success. The comparison of costs is absolutely useless to assist in determining the probable return. You may spend almost any initial sum you please upon a line, and the cost per car mile may be large or small. Whatever it be, if the return per car mile be above that cost, the total return will be large or small according to the total number of car miles run. Our interpretation of the articles of association and prospectus is that the company is fully alive to all these ideas, that it starts with a free hand, shackled to no system, but ready to adopt the best system demanded by the circumstances of each case. There is just one point whereon our views may not accord with those of a pioneer company. The municipalisation of tramways is not on the same footing as the municipalisation of electric light distribution. The latter we unhesitatingly advocate without any reservation; the former is not so great an article of faith, yet it may often be expedient. Even granting such expediency, the sphere of action is so large that neither this company nor any it might promote could hope to fill the field, and so, by providing the service required by the public, ought to have excellent chances of success.

Electric Lighting in Shanghai.—The *China Gazette* says the electrical department of the Municipal Council now runs 140 arc lamps, lighting some 15 miles of streets, and there are about 43 miles of line wire laid in addition to 6,100 incandescent lamps of 8 c.p. each for domestic purposes."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

EXPLANATION.

SIR,—Notices have appeared in your paper and elsewhere of a company styled the "British Electrical Manufacturing and Engineering Company, Limited," in the prospectus of which our name appears very prominently.

As this prospectus has been framed and issued to the public without our knowledge or consent, we shall be obliged if you will allow us space to explain the circumstances, as far as we know them, and to correct an inaccuracy, which is important to us and may be misleading to the public.

Finding that for our own work exclusively we could not advantageously run our brass-finishing works, and as it is not part of the business of electrical engineers to conduct works of this kind for the *sale* of brasswork, we determined to dispose of the machinery and stock in this department; accordingly we had agreed to sell them to the gentleman who appears as the vendor to the "British Electrical Manufacturing and Engineering Company, Limited."

We were expressly assured that no prospectus of any kind would be publicly issued, and as we feel that in the one which has come out, contrary to this assurance, much has been made of a concern which so far as our share in it goes is of very slender proportions, and our name is used appearing so that the public would naturally think we had authorised what is said, we wish to disclaim all responsibility for the announcement.

It is not true that we have undertaken to give the new company all our work. The fact is that we have engaged to give them our orders for similar goods to those which we have heretofore ourselves made at our works, provided that they can do them as well as to workmanship, price, and conditions as we can get them elsewhere.

There is, beyond these orders, no goodwill in the department, and the expression that the company has acquired the goodwill of our manufacturing department is very misleading.—Yours, etc.,

LAING, WHARTON, AND DOWN.

New Bond-street, W., November 11, 1895.

THE CAUSE OF CHANGE OF LENGTH IN IRON WIRES UNDER MAGNETISM.

SIR,—The experiments which Dr. L. J. Moore, of Johns Hopkins University, has conducted and communicated to the *Philosophical Magazine*, relative to the changes in length of iron wires under magnetism, are more especially interesting to me, because, when coupled with a series of experiments which I conducted some years ago, they prove the deductions which I was led to make and the theory which I then advanced as to the nature and cause of magnetism to have been quite correct—viz, that magnetic phenomena are due to a property which magnetic matter possesses by induction of causing polar phenomena by action and reaction at the pole points.

The most ready method, perhaps, of showing the reason of the changes in length of iron wires when they are magnetised will be to describe again the experiments to which I have alluded, and to restate and explain the theory which I deduced from them.

Taking two bars of steel, as equal in magnetic power as I could render them, I placed them together in every sort of position, and by watching the behaviour of fragments broken from the pointed ends of needles I examined and tested the lines of magnetic force in every instance. I thus proved (1) that the equator of bar magnets is always oblique (*vide Proceedings* of the Royal Society, April 24, 1879); (2) that the cause of the poles of a bar magnet not being situated respectively at its extreme ends, but at some little distance short of them, is due to the effect of lines of reactionary force which pass from the ends of the bar to meet those which come from the equator, the polar line marking the position where these forces collide and are ejected from the bar.

I will explain precisely how I arrived at this conclusion, because it has a most important bearing upon the cause of magnetism. When two similar poles of bar magnets of equal

Digitized by Google

power were approximated, the needle points which had been placed upon the line of the magnetic pole of each bar gradually fell, and they could not be made to resume their more or less vertical direction until they were placed over the line of contact of the two bars. If the magnets were of unequal power, the polar line would be found on the stronger bar; and in proportion to the disparity of force between the two magnets, it would be at a greater or less distance from the bar end. The other positions assumed by the needle points as they approached the new polar line from either direction were identical with those which they took on a single bar magnet when moved in the direction of the polar line. On the other hand, when two dissimilar poles were placed together, almost all polar manifestations vanished, and the phenomena at the point of contact then tended to become like those at the equator of a single bar magnet; and they might be compared to the magnetic phenomena which are exhibited by a copper wire whilst conducting an electric current By these and other experiments I have satisfied myself that one of the distinguishing differences which exist between magnetic and diamagnetic matter resided in the property which magnetic matter possesses by the induction of reactionary force from the bar ends, of thereby throwing outwards from its poles the force which has traversed it in each direction—viz, from the equator to the poles and from the poles to the equator—a property which diamagnetic matter does not possess. In fact, the lines of force which are exhibited at the polar points are the counterpart of those which are shown by iron filings when two similar poles are approximated, only when these lines occur in the bar matter they are as permanent as are the phenomena of magnetic polarity, because the bar matter inherently possesses the power of thus dealing with the force or the stress which is acting upon it.

In this experiment of the approximation of similar poles of two bar magnets beneath a paper sprinkled with iron filings, we have a visible demonstration of the manner in which the polar phenomena are brought about. As the two similar poles are pushed from opposite points towards one another, the lines of force coming from either pole, as marked by the iron filings, are driven backwards and outwards by the corresponding lines of force coming from the opposite bar, until at length, when the bar ends touch, the phenomena are identical with those which are found to exist at and about the polar point of a magnet.

We are thus able to show why the changes of length determined with such accuracy by Dr. L. J. Moore occur:

1. When the oblique forces on the surface of a bar magnet meet with precisely similar oblique forces from the opposite direction, they tend to collide with them at a definite point—*i.e.*, the pole point, and to take a new direction—a direction which is the resultant of all the forces acting at the colliding point.

2. The primary effect of inducing magnetism in an iron bar or a wire is to cause a definite arrangement of the molecules, whereby their poles, in accordance with the character of their polarity, are made to point more or less north and south. Thus, the long axis of each molecule is placed parallel with the axis of the bar. And as this molecular arrangement commences from the equator and from the bar ends at the same time, the induction of magnetism in a bar tends to elongate the bar simultaneously from the poles to the equator, and from the equator to the poles.

3. As the forces approach each other from opposite points, in curved lines (the curves being equal) they collide and are thrown outwards, and the direction of the molecules is thus turned outwards to the surface of the bar, and shortening of the bar occurs.

4. The shortening of the bar would be in proportion to the intensity of the force and to the dimensions and purity of the bar matter, because certain definite relations must exist between the projection of force from the poles and the capacity of the bar matter for magnetism.

5. Any force in excess of that which gives definite arrangement to the molecules—*i.e.*, the magnetic capacity of the matter—must be productive of irregular molecular motion, diminution of polarity, and heat by molecular friction.—Yours, etc., R. C. SHETTLE, M.D.

Reading, November 7, 1895.

INSTITUTION OF CIVIL ENGINEERS.

The first meeting of the session 1895-96 was held on November 12, when a portion of the new building, comprising the theatre and approaches, with tearoom, etc., was made available for the purposes of the evening.

The chair was taken by Sir BENJAMIN BAKER, K.C.M.G., LL.D., F.R.S., the new president, who delivered his inaugural address. After some preliminary observations referring to the position of the institution in the domain of engineering, and the necessity of British engineers acting together in a true spirit of comradeship throughout the world, the president proceeded to discuss the question why engineering, unlike other liberal arts, was an essentially modern profession. Was it because the modern demand for rapid transit, often as purposeless as that of a record-breaking cyclist, had not its equivalent in the past, or was it because our ancestors lacked the inventive power and mechanical ingenuity of the present age? The artificers who built the highly ornamental barge in which Columbus blundered across the Atlantic could, with the same materials and workmanship, have constructed a clipper ship capable of sailing 300 miles in a day; but no one asked for speed in those days. On the other hand, although the present was pre-eminently an age of invention, an impartial survey of actions and events recorded in history would satisfy most people that in all ages there were to be found men no less intellectual and enterprising than ourselves. The general answer to the question raised would probably be that as it was only in the present century that people had insisted upon rapid locomotion by land and water, so it was the necessity of meeting that demand which had created the profession of modern engineering. When Watt directed his attention to the steam-engine, the country was weary of wars, and longed for the advancement of its material prosperity, and so a demand was created, and the country quickly became covered with canals, roads, and factories. At that time England depended largely upon her American colonies (now the United States) for the supply of iron, and in 1751 an Act was passed admitting American bar iron duty free to London, but prohibiting its cartage therefrom to Birmingham, as it was desired to make London, instead of Birmingham, the chief seat of the iron manufacture of the country. No one foresaw that Great Britain was to become the leading iron-producing country of the world. On all subjects, indeed, the most eminent men constantly failed in their forecasts. Smeaton did not believe in the steam-engine as proposed by Watt; Telford had grave doubts as to the practicability or usefulness of the Liverpool and Manchester Railway; Sir Robert Peel, 60 years ago, blocked a proposal in Parliament to make all the railways seeking access to London adopt a comprehensive plan for a central exchange station, so that through passengers and mails might be saved cabbing across London; Lord Brougham tried, in 1857, to make 30 miles an hour the statutory limit of speed on railways; Lord Palmerston told the House of Commons that the Suez Canal was one of those bubble schemes often set on foot to rob the English capitalist, and even Robert Stephenson, following him, declared it to be, commercially speaking, impracticable. All these mistakes, however, became insignificant when contrasted with the gigantic blunder, acquiesced in by the whole civilised world, of assuming, at the time of the Great Exhibition of 1851, that the efforts of the engineer would effect an immediate change in the long inherent savagery of mankind, thereby inaugurating a period of universal brotherhood and peace. Civil engineers were often reproached for devoting their ingenuity to the devising of man-killing appliances, but with little reason; for no one could fail to see that whatever might be the abstract principles of Christianity, in practical politics they were disregarded, it being always taken for granted that if a nation possessed that which another nation might covet, it must be prepared to defend its possession at the point of the sword.

It has been frequently assumed that everyone acknowledged the benefits conferred upon humanity by engineers in facilitating communication, cheapening production, and raising the condition of the toiler; but the late Prof. Froude

Digitized by Google

had publicly stated that he failed to see much evidence of progress in the nature of men, and that "Even in the outward essentials of food and clothing and housing it is not certain that the mass of mankind in the present generation are better off than their forefathers." The president was not prepared to accept this dictum, and maintained, on the contrary, that the mass of mankind were much better off than their forefathers in these respects. Further, that the independence of the labourer and mechanic had been greatly advanced in consequence of the vastly increased demand upon their services due to engineering work. In support of this view, it was stated that as recently as four years after the opening of the Liverpool and Manchester Railway, certain Dorsetshire labourers ventured to erect themselves into an elementary form of trade union, and were sentenced to seven years' penal servitude for their pains. At the present time many municipal contracts provided for payment of wages at trade union rates, whereas a couple of centuries ago the magistrates fixed the rate at quarter sessions according to the price of food and clothing, the average being about 1s. a day for carpenters and masons, and 8d. for labourers. The hours of labour for all classes were from 5 a.m. till 8 p.m., with 2½ hours' interval for meals and rest. The penalty for an employer who departed from these regulations was 10 days' imprisoment and £5 fine, and for a workman 21 days' imprisonment. No man in search of work could beg without a license, the statutory penalty for a first offence being whipping at a cart's tail; while the second offence meant the loss of an ear and two days' scourging; and the third, hanging. On the whole, the study of the past was conclusive as to the material and moral progress which had accompanied the development of engineering works.

The president next dwelt upon the work done by physicists in the borderland of engineering, and expressed the opinion that long before the coalfields were exhausted some way would have been discovered of tapping the inconceivably great reservoirs of force in Nature still untouched. Although no one could foresee the demands of the next age, new wants constantly arose, and new branches of engineering often resulted from apparently trivial laboratory experiments.

In conclusion, the president sounded a note of warning against the growing disposition to overrate technical education. Education would do much, but it would not endow a man with common sense, nor would it make his opinion on a multitude of important subjects worth more than that of any naturally observant person. There were not wanting contractors and manufacturers who contended that some of the highly-trained young engineers of the present day were not wholly free from a tendency to overmuch reliance on formulas, without due regard to the sufficiency of the data upon which such formulas were based. Such faults were best remedied by joining in practical discussions with other engineers, such as it was a province of the Institution of Civil Engineers to encourage.

After the delivery of the address the president presented to the recipients or their representatives the medals and premiums awarded for papers presented last session.

THE ADVANCE OF THE ELECTRIC RAILWAY MOTOR.*

BY G. T. H.

No dynamo-electric machine has in so short a time been more radically changed and more efficiently improved than the electric railway motor. When it was demonstrated that it was possible and practicable to operate a street car by electricity, all of the large electrical manufacturing companies designed motors for this service; but it is never possible to break completely away from old ideas, and in no case has this tendency been more apparent than in the case of the electric railway motor. Modern practice has shown us how necessary were these radical changes. At the beginning of electric traction the electric motor which the manufacturers had already produced possessed the following characteristics: first, high speed; second, severe sparking at change of load; third, extreme susceptibility to dust and water; fourth, need of constant attention; fifth, weak torque or turning moment; sixth, great weight for power supply; seven, unsightly over-wound drum windings.

This motor when used for traction had to work under the following conditions: first, without any attention whatsoever; second, with water, dust, or mud present at all times; third, with severe starting torque; fourth, heavy changes of load at all times; fifth, constant vibration; sixth, no lubrication; seventh, operation under the care of an inexperienced man. Any two more incompatible states of conditions and requirements could not be devised. These adverse conditions are the same to-day as they were then, but the motor has been improved to meet them. Every part of a modern railway motor has been especially designed for the purpose, and has passed through a series of changes both interesting and instructive.

There are three important vital parts of an electric railway motor—the armature, the commutator, and the field magnet. Other important parts are the brushes, bearings, and the gears. Taking the armature first, the original type was taken directly from the stationary motors which were then manufactured with plain surface-wound rings and drums. The compact drum armature had many attractions, but the trouble from the over-wound heads gave the ring armature an advantage, as did also the fact that the greater relative distance of the movable wire from the axis gave greater torque and slower speed. It is a well-known fact that it is not possible to economically wind a bipolar drum armature whose length is not at least one and one-half times its diameter. Therefore, the drum armature, to approach the "over-all" diameter of a ring, would be excessively long, and of greater power than required. Still, this great advantage did not permit the ring armature to attain a single reduction of power any sooner than the drum. Both seemed to make the transition simultaneously. The ring armature had and still possesses the advantage that, in the event of sections burning out, they can be rewound without disturbing in any way their fellows. This is an advantage which is not claimed for any drum-wound armature now built. In the early days of electric motors the drum-wound armature had a mechanical advantage that was not to be underestimated. It was possible to secure the lamellar core of the drum armature upon the shaft in a much more rigid and mechanical manner than that of the ring. Summing up the case, the ring armature was preferable, but the persistent conservatism of many manufacturers of drum armatures and the radical improvements that have been made have done much to make the drum armature superior to the ring, in the eyes of many users.

Up to the time that electric motors came to be redesigned for street railway propulsion, the toothed armature was looked upon with great suspicion as liable to involve spark troubles of a most serious nature. However, the fact that a much lighter equipment would result from the use of toothed armatures caused expert designers carefully to study the problem and effectually solve it. Thereupon both the ring and drum armatures became toothed, and great economy in weight and magnetic power was thus effected. But this change to toothed armatures was a great advantage to the drum type. With surface-wound armatures it is a fact that unless at least two wires are wound in a section it is impossible to have the coils symmetrical, of the same shape and resistance and, at the same time, compact.

Compact, symmetrical windings for surface-wound armatures existed before electric railroading, but for some reason they were never generally adopted. The teeth between the wires on the drum armature give sufficient room to connect the conductors either in a spiral path in the plane of the head of the armature, or diagonally on the cylindrical surface of the armature produced. Two layers of wires are all that are required, and each connector has its path partly on the upper and partly on the lower layer. Each coil may now be machine formed, and identical in shape with its mates. They pack closely into the space provided for them, each one having just room enough and no more.

* *Electric Railway Gazette.*

Digitized by Google

Thus they mechanically lock each other in position, and form a well-insulated structure, as it is possible to insulate the coil separately before slipping it on to the core. In the event of a coil being injured or burned, by slipping off a few coils the injured one can be removed or replaced, while the uninjured coils that were removed are not in consequence destroyed, as was the case with the old over-wound drums.

The time employed in placing the coils on the core is but a few hours, and many companies now claim that two of their armatures of this type can be completed, as far as winding and connecting is concerned, in one day and by one man. This gives the drum armature prestige over the ring where the ring was formerly superior.

The advent of the multipolar fields facilitates the use of separate coils to even a greater extent, for no rigid rule as to length and diameter need be adopted to secure an economical winding. The present standard motor for street car propulsion has a toothed multipolar drum armature wound with machine-formed coils. It is the product of successive ideas and their application, and is meeting with deserved success.

It has seemed singular that the present iron-clad motor did not sooner come into general use, as iron-clad machines existed before electric railroading, in the inventions of Eickemeyer and others. Nevertheless, manufacturers seemed to prefer to use their own distinctive types, whether they were suited for the purpose or not. The reason is partly to be found in the convincing force of the oft-repeated statements of each maker that his special type is the only rational and practical form suitable for any service, and partly in the maker's desire to exercise an economy by the use of existing patterns and calculations, even though that economy be a false one. Therefore, these makers took one of their existing frames that had given good service as a motor, and redesigned it for service under a car. Lugs and arms were cast on to the frame, the brushes rigidly fixed, the field magnet series wound, and thus equipped it was sent out for active service. As everyone remembers, it did not accomplish its mission. It came back to the shop in a few weeks incrusted with dust and mud, with both armature and magnets disabled. The motor was laboriously dismantled, its magnets were removed and rewound, so that it soon became apparent that the use of movable coils for field magnets would greatly facilitate repairs. The motor was then put together and provided with an elaborate enclosure made of sheet iron and rubber cloth, which added to the weight of the equipment. However, this state of things was not to last.

The obstacles that had been met with were very discouraging, and it was clear to everyone that a new type of field magnet was necessary. First, the motor must be constructed in such a way that it could be more easily taken apart for repairs; second, it must be protected from dust and mud; and third, it must be lighter. The first of these requirements was found in a motor of the hinged type that could be readily opened when repairs were necessary. The second problem was more slow in solution, but eventually was perfectly solved with the development of the iron-clad type of motor. In this type the motor becomes its own dust-proof enclosure.

In the meantime the electrical side of the question had not been neglected. Soft steel enabled designers to produce a motor with an intense magnetic field. This gave a slow speed and starting torque sufficient for a single reduction of speed. Then it was that several too sanguine inventors overshot the mark and produced a gearless motor. Not that the gearless motor was by any means a failure, but the particular interurban and long-distance service that it is fitted for was not then demanded, and the motor proved to be a failure in small sizes and in crowded sections. The boom of the gearless motor, therefore, subsided, and anything of that type is always suspiciously regarded by street railway officials. However, the single-reduction motor was received with great favour, and has become the standard among all street railway companies. Manufacturers differ in methods of connection and the number of coils they use to obtain the multipolar field, but they are unanimous in adopting multipolar types. The street railway motor has now reached such a state of perfection with regard to its windings that it would be difficult to imagine an accident to it that would involve more than a day's work for two men.

Rapid and radical as the changes have been with armature and field magnet, the commutator, which, after all, takes a very heavy duty of the machine, has been but little improved. In one way this is not the designer's fault. Mechanically, nothing could be better than the rigidly-built commutator now in use on railway motors. The bars are drop-forged, the mica insulation is of the best, and the whole is solidly clamped together under enormous preseure, yet it is well known that a commutator on a railway motor is of very short life. Dust has been effectually excluded from the commutator, but the evil of sparking is still there, and will continue to gnaw the commutator away until it is cured. Sparking on an ordinary railway motor of good design and otherwise in perfect condition results from two causes: first, dirt on the commutator; and second, improper position of the brushes. The proper position of the brushes is on the neutral line which fluctuates back and forth with the work the motor is doing. Either this fluctuation must be stopped by some method of winding which will counteract the armature reaction, or else the brushes must be moved to follow it. Neither has been done. The modern well-designed street railway motor has quite a wide non-sparking zone, but the dirt which will inevitably collect is sure to aggravate sparking, thus narrowing the zone, and unless the brush is in exactly a non-sparking position the commutator will be worn away. Inventors have suggested methods for making the neutral line stationary, but this does not seem to have met with popular approval. Common practice is to clamp the brushes firmly in the position which is found to be the best average, and the commutator is removed if required. Perfection for traction motors cannot be claimed until a machine is produced that shall have long and equal life in all its parts.

The sweep that the brushes of a railway commutator take in exactly following the neutral line in its fluctuations is much larger than on any dynamo or stationary motor, because of the fact that the motor is required to reverse. If there were absolutely no armature reaction there would be no shifting of the neutral line, which would then be situate exactly between the pole-tips, provided that no lead had been given to the armature connections. As it is, the conditions are as follow: When the motor rotates, say, in a right-hand direction, the neutral line rotates in a reverse direction, and the greater the load the further it extends. When the motor is reversed, the direction of the neutral line also reverses, and is entirely on the other side of the position that it assumes at no load. Therefore, a street railway motor or any motor which runs as much in one direction as the other, should have twice the range of brush adjustment which would be necessary if its direction of rotation was uniformly the same. There is urgent need of action on this matter, for at present the case is of the worst possible description, and is costing yearly many thousands of dollars. Street railway practice at present dare not risk the complications of a brush-adjusting device attached to the controller spindle. It would be well to consider the advisability of two non-sparking positions, one for forward and one for reverse motion, to be operated when reversing the car for the return trip. The commutator is, and for some time to come will be, the weakest part of a railway equipment, until some day our hopes are realised and the induction motor will propel railway cars.

CARBORUNDUM AT NIAGARA FALLS.

As we have already announced, on October 19 one of the furnaces of the Carborundum Company was put in operation, the electric current being obtained from the Cataract Company's power-house. A 2,200-volt current comes into the carborundum factory, which current is transformed into one of 7,000 amperes at a pressure of 185 volts. The transformer in which this conversion takes place is said to be the largest in the world. The

Digitized by Google

furnaces in which carborundum is made are built of brick, and are each about 15ft. long, 7ft. wide, and 6ft. high. In the centre of each end wall of the furnace is a large bronze plate, to which are connected four large copper cables, carrying the current from the transformer to the furnace. Connected to each of the bronze plates are 60 carbon rods, each about 2ft. long and 3in. in diameter. These rods, which project through the walls, form the terminals of the conductors. The furnace is charged with the proper substance (sand, salt, coke, and sawdust), and through the centre of the mixture a core formed of fine grains of coke is built up, which serves as a conductor of high resistance between the terminals. When the current is turned on, it raises the contents of the furnace to an enormously high temperature, at which the chemical change that produces carborundum takes place.

ST. PANCRAS LIGHTING SCHEME.

The following is the report of Mr. Sydney W. Baynes, chief electrical engineer to the Electricity and Public Lighting Committee of the St. Pancras Vestry, respecting increased voltage for distribution of current:

Pursuant with instructions, I beg to submit the following report setting forth the advantages to be had by the employment of higher voltage for the distribution of electricity from central stations.

In 1877 the first incandescent Swan lamp was produced, but it was not a commercial article in the sense we now know the incandescent lamp, because its voltage was too low, being only 50, and therefore worthless for central-station distribution. In 1881 Edison inaugurated his central-station system with lamps of 100 volts, and in consequence the Swan Company were compelled to manufacture their lamps at double the original voltage. This gave considerable impetus to the electrical industry, being quickly followed by the establishment of central supply stations throughout the country. At this present date the old 50-volt lamp is obsolete, and a number of first-class lampmakers are producing lamps of 8 c.p., 16 c.p., and 32 c.p. and upwards at various voltages up to 250.

When I first introduced the higher-voltage movement, some two years ago, I had numerous enquiries from American engineers as to the success of the scheme. While in England we creep slowly on our American friends push boldly forward, and the change there is making rapid progress, especially in the Edison stations. Edison has expressed himself to the effect that a higher-voltage direct supply is the system of the future.

When commencing my duties in St. Pancras I found that a number of premises had been wired ready for connection to the mains from the King's-road station, and I learned that no instructions had been issued to the wiring contractors as to the subdivision of the circuits so as to enable a supply to be given on a five-wire system. Experience elsewhere has shown that no service line should carry more than 10 to 15 amperes, and it has become the rule to run the five services into the majority of the houses; in this way a potential difference of 440 volts frequently exists in the buildings, but so far no trouble has been experienced by the consumers from this cause.

Our customers having their premises already wired could not readily comply with the requirements consonant with the five-wire system, neither could we call upon them to rearrange their wiring, but we could supply them with increased voltage which would only need two service lines and suit the arrangements already made.

A further advantage is the saving in the cost of house services. The average cost of coupling up a customer with lead-covered cables amounts to about £6 where a two-wire supply is given; each additional wire, including its main switch and cut-out, may be estimated to cost about £2, so that where a five-wire supply is needed each house will cost £12 for service lines. Should a customer demand a day and night supply, the expense and complications involved would render such an arrangement clumsy and impracticable On a 220 volt supply these difficulties would not be met with, as only a two-wire service would be necessary.

The royalty claimed by the Westinghouse Company for the use of Hopkinson's patent had also to be dealt with. It transpired during correspondence on this question that the money paid on the Stanhope-street mains did not cover the use of a five wire system over the area supplied by the existing mains and the company stated that had this been contemplated their charges would have been in the neighbourhood of £28 per ton of copper laid, instead of the £11 per ton they had received.

Had we connected our five-wire extensions to the old system and run the two together a further payment of some two or three thousand pounds would probably have been demanded. I am able to speak with some authority on this point from past experience with this company, where a parallel case had to be dealt with, and finally payment was enforced.

In the original estimate for the King's-road works the royalty was set down at £1,200, but this was based on a three-wire agreement. Taking it at £28 per ton, as intimated by the company for a five-wire agreement, it would amount to close on £3,000, or a total additional payment over the old and new works of some £5,000. In order to deal with the question in an effectual and diplomatic manner, and having regard to other advantages herein stated, the circular of September 1, 1895, was issued to the wiring firms, intimating the introduction of an increased voltage. The company know full well the advantage of the high voltage, and that by its introduction we could do more for our Stanhope-street mains than by a conversion into a five-wire system, and further that we could meet all present demands on the King's-road works by the employment of this voltage on a two wire system, free from royalty. Consequently, we have been able to secure the privilege of using any multiple-wire system on our Stanhope-street mains, or any extension thereof, without increased royalties, and the charges on the King's-road mains have been reduced to a lump sum of £750 on 110 tons of copper laid. If the circular of September 1, 1895 never effects more than this, it has done excellent service. I hope to show, however, as briefly as possible, that the advantages to be derived from the use of the higher voltage have a very important bearing on the future of electric lighting.

A station delivering current at 220 volts to the lamps will possess the following advantages over that delivering at half the pressure. With the same expenditure in copper we can do four times the lighting on the mains, or the same amount of lighting at four times the distance with the same percentage loss; consequently the area that may be covered by the higher-volt station is 16 times greater than that of the low.

The lighting from the low voltage is unsatisfactory, because of the excessive fall of pressure along the distributing mains and in consumers' premises. This is very difficult to remedy, being almost unavoidable without extravagant use of copper. Frequently a fall of 2½ volts occurs in the consumer's wiring, reducing the light given out by his lamps by 13 per cent. If the voltage were increased to 220, the variation in the lighting would be so slight as to be inappreciable.

The increased copper on a five-wire system at 110 volts compared with a three-wire at 220 volts is about 50 per cent., so that in extending mains from the King's-road system only three mains are needed; hence a considerable saving in capital will be effected.

No further transformer sub-stations will be required, a point which alone tends considerably towards economy both in working

Digitized by Google

costs and upkeep. Moreover, it is undesirable to have either machinery or battery stations at numerous points throughout the parish, as all apparatus of the kind requires constant attention.

In regard to the Stanhope-street mains, from numerous complaints received, it is evident the old mains in several districts are overtaxed, although not 50 per cent. of the customers along the route have been dealt with. Whether we now augment these mains by the increased voltage, or convert them into a five-wire arrangement, the risk of breakdown to earth, both on the consumers' premises and on the mains, is unaltered. If the 220-volt system is introduced, we may either increase the capacity of these mains fourfold, with the same percentage loss, or twofold, with half the percentage loss.

With the increased voltage the plant used for lighting will be identical with that for electric traction, therefore our plant would afford excellent facilities for combining lighting with electric traction throughout the parish, no extra generating plant being required.

Any modification which will effect a saving, either in the production of current or in its distribution, must ultimately benefit the ratepayer and consumer alike.

The increased voltage to consumers' premises does not in any way at the present stage infringe the requirements of the provisional order, because we read, Section 27 (*e*), "the standard pressure may be different for different points of any main," etc., "but it shall in all cases be within the limits following."

The limits are in the case of continuous current not less than 30 volts nor more than 300 volts. [The original order only allowed up to 200 volts, but was increased by the Board of Trade to 300 volts in November, 1890]

(*d*) "The 'standard pressure' shall be fixed by the undertakers for every main, and shall not be altered except after notice to the Board of Trade," etc.

The standard pressure on our mains is unaltered, and it is not intended to vary it at the present stage, neither will the old customers' voltage be changed without following the instructions contained in Section 27 (*d*).

PHYSICAL SOCIETY.

At the ordinary meeting of this society held on the 8th inst., Prof. A. W. Rücker, vice-president, in the chair,

Mr. W H. Everett read a paper on "**The Magnetic Field of any Cylindrical Coil or Plane Circuit.**" The method of treatment is based on the formula for the force due to an element of current. A single integration applied to one component of this force gives for any point in the field due to a plane circuit the force perpendicular to its plane, and a double integration gives the longitudinal force at any point due to a cylindrical coil of any cross-section, the depth of winding being supposed inconsiderable. For coils in which the latter condition does not hold, an approximate solution can readily be found. The force parallel to the plane of a circuit and the transverse force due to a coil are investigated in a similar manner. The general results are of a very simple form, and admit of easy approximate calculation. Special formulæ are deduced for coils of rectangular cross-section, the general expressions being in this case integrable Appended to the paper are some numerical results giving the values of the forces at different points due to coils of various dimensions.

Prof. Perry said he considered the paper to be a valuable one, particularly as illustrating a practical mathematical method of integrating.

Mr. Trotter said the paper was of interest to him, as he considered that several of the author's results might be applied to the solution of problems on illumination, *e.g.*, the illumination of a room by a circle of lamps.

Mr. Rhodes regretted that it had not been possible to supply a proof of the paper before the meeting. The method, in which the author obtained the force outside a solenoid as the difference of the forces due to two solenoids, reminded him of the method employed in calculating the attraction of, say, a truncated pyramid.

Prof. Silvanus Thompson said the author had mentioned several previous papers on the subject, but had not referred to one by Prof. Viriamu Jones, in which the force due to a solenoid is obtained in terms of elliptic integrals. Another method of attack was to calculate the work done when a unit pole is carried through the solenoid and back outside to the starting point.

Prof. Ayrton said he also regretted the absence of a proof of the paper. He considered it of great importance to have exact and simple methods of calculating the forces due to a solenoid.

The **Chairman** (Prof. Rücker) said he had made a somewhat similar calculation in connection with the magnetic effect of sheets of basalt below the surface of the earth.

Mr. E. H. Griffiths read a paper by himself and **Miss Dorothy Marshall** on the "**Latent Heat of Evaporation of Benzene.**" The method employed is similar to that used by one of the authors in the determination of the latent heat of evaporation of water (*Phil. Trans.*, 1895). The loss of heat due to the evaporation is balanced by (*a*) the heat supplied by an electric current; (*b*) a secondary supply due to the work done by the stirrer; (*c*) a slight gain or loss due to small unavoidable changes in temperature of the calorimeter. The comparative values of the various sources of heat (if we denote the supply due to the electrical current by 1,000) is approximately: electrical = 1,000; stirring = 11; changes in calorimeter temperature ± 5. The electrical supply could be measured with extreme accuracy, and the above table shows that small errors in the determination of the remaining thermal quantities are of little importance. The results may be summed up in the formula

$$L = 107{\cdot}05 - 0{\cdot}1581\,\theta,$$

where θ is the temperature and the thermal unit at 15deg. C is used.

The discussion on this paper was postponed till after the reading of the paper by **Prof. Ramsay** and **Miss Marshall** on "**A Method of Comparing the Heats of Evaporation of Different Liquids at their Boiling Points.**" The method employed has already been described before the society (January 11, 1895). The liquid to be experimented on is put into a glass bulb enclosed in an outer jacket filled with the vapour of the same liquid. An open tube is attached to the top of the bulb, so that there is free communication between the interior and the vapour jacket and no loss of material. Inside the bulb is a spiral of fine platinum wire, attached to stout platinum terminals, which are sealed into the glass. The temperature of the liquid in the bulb is raised to the boiling point by the vapour jacket; thus when a current is sent through the wire the whole of the heat developed is spent in converting a portion of the liquid into vapour. Two such bulbs are connected in series, and the ratio of their losses of weight is the inverse ratio of the heats of evaporation of the liquids. A correction is made for the inequality in resistance of the spirals, and the ratio of the differences of potential between the ends of the spirals, when the current is passing, is determined in each experiment by Poggendorff's method. Results are given for 14 liquids.

Prof Ramsay drew special attention to the table giving the values of the quotient, $\frac{ML}{T}$, where M is the molecular weight, T the absolute temperature, and L the latent heat. Very curious differences are noticeable in the case of water, alcohol, and acetic acid.

Prof. Carey Foster expressed his admiration for the method, since it obviated the necessity of knowing the specific heat of the liquid or vapour.

Prof. Silvanus Thompson said the difficulty experienced in the case of water due to electrolysis might be obviated by the employment of a spiral of lower resistance and a larger current, so that the difference of potential between the ends of the spiral should be less than 1 7 volts.

The **Chairman** said Captain Abney had asked him to enquire to what extent the temperature of the liquid was affected by radiation.

Mr. J. W. Rodger asked if any direct experiment had been made to determine if the temperature of the liquid was not above its true boiling point. In some cases differences of as much as 2deg. might exist between the temperature of the liquid and that of the vapour given off. The differences in the value of $\frac{ML}{T}$ in the case of water, alcohol, and acetic acid might be due to the fact that the vapours of alcohol and water were simple, while the vapour of acetic acid was complex.

Mr. R. Appleyard suggested that the differences obtained in the case of water might be due to the presence of dissolved air.

Mr. Griffiths said that the objection to the adoption of Prof. Thompson's suggestion was the fear that with short wires an excessive difference in temperature between the wire and the liquid might exist.

Mr. Rhodes asked if Mr. Griffiths could trust his determinations of temperature to the 80,000th of a degree?

Mr. Griffiths, in reply, said that he thought there was no limit to the accuracy with which a difference of temperature could be measured. The absolute temperature, however, he only relied upon to $\frac{1}{1000}$th of a degree.

Prof. Ramsay said the fact of superheating existing would not affect the results, since near the temperatures at which they were working the latent heat did not vary appreciably with the temperature. In reply to Captain Abney, he said some previous experiments by Dr. Young and himself had shown that the vapour jacket was quite impervious to radiant heat from without.

LEGAL INTELLIGENCE.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY v. EBBSMITH.

On Monday last, in the Court of Appeal, consisting of the Master of the Rolls and Lord Justice Kay, the appeal of the plaintiffs from an order at Chambers of Mr. Justice Hawkins was decided. The appeal had been postponed from Monday, 4th inst., under circumstances reported in our last issue. The plaintiffs alleged in their statement of claim that Ebbsmith was the promoter and solicitor of the South Staffordshire and Birmingham District Steam Tramways Company, Limited, which was taken over by the plaintiff company, and that while occupying that fiduciary position he formed a company called the Dickinson Tramway Appliance Company, Limited, which company was a sham, being, in fact, Ebbsmith himself; that certain patents were bought up for small sums by Ebbsmith and assigned by him to the Dickinson Company; and that Ebbsmith then procured the plaintiff company and their predecessors to purchase articles, the subject-matter of the patents, and licenses to use the patents at exorbitant prices and without any disclosure of his interest in the patents. The plaintiffs claimed damages, an account of the defendant's profits, and a rescission of the plaintiffs' contracts as to the patents. On the application of the plaintiffs, the Master made an order under the Bankers' Books Evidence Act, 1879, that the

Digitized by Google

plaintiffs should be at liberty to inspect at the Metropolitan Bank, Limited, the books of the Staffordshire Joint-Stock Bank, Limited, and their successors for the years 1885 to 1894 containing entries of the accounts of Ebbsmith in that name and in his former name of Joseph Smith, and of the Dickinson Company. Mr. Justice Hawkins reversed this order, and the plaintiff company appealed. On behalf of the plaintiffs affidavits were read which had been sworn by the plaintiffs' solicitor, Mr. Munns, by Mr. Hatchet, who was secretary to the plaintiffs, and who had been secretary to the South Staffordshire and Birmingham District Steam Tramways Company, Limited, and by Mr. Holmes, who had been cashier to the defendant and secretary of the Dickinson Company. It appeared that the signatories of the memorandum of association of the Dickinson Company were the defendant's partners and clerks, and that out of the 1,507 shares in that company the defendant had originally, and for some two or three years after, held 1,500. In 1889 the 1,500 shares were transferred by him to one of the signatories of the memorandum of association, who had previously held one share, and subsequently they were transferred to the Corporate Trust, Limited

Sir Frank Lockwood, Q.C., and Mr. Scrutton appeared for the plaintiffs, Mr. G. Spencer Bower for the defendant, and Mr Loehnis for the Dickinson Company.

The Master of the Rolls, in dismissing the appeal, said that the application was for liberty to inspect the accounts in the books of the Staffordshire Joint-Stock Bank of the defendant Ebbsmith and also of the Dickinson Tramways Appliances Company. Taking the first of those two accounts, he had no doubt that the Court had jurisdiction to make the order applied for. The question was how the Court was to exercise that jurisdiction. The extent of the power of the Court in ordering inspection of documents before trial was regulated by decisions amounting to rules, and the rule, before the passing of the Bankers' Books Evidence Act, 1879, was that the Court had power to order such inspection, subject to an answer which might be made in an affidavit by the person against whom the application was made. The Court would accept his answer, made on oath in an affidavit, and it could not be contradicted by affidavits in reply, but he would be left to the risk of being subsequently found out to have sworn falsely. The application in the present case was made under the Bankers' Books Evidence Act, 1879, but in the opinion of the Master of the Rolls the Court should exercise its jurisdiction under that Act in accordance with the rules of the Court in other applications for inspection. Therefore, as the defendant had here sworn an affidavit that the items in his banking account which he had there given were the only items in it which were relevant to the issue in the action, the Court must, for the purposes of that application, accept and act upon what he had sworn. The Court must refuse to order inspection before the trial, and would leave the judge at the trial to make any order that he might then think fit. Then as to the account of the Dickinson Company, he (the Master of the Rolls) had no more doubt in that case than he had in the case of the defendant that the Court had jurisdiction to make the order asked for. That seemed to him to be clearly the law, and the reasons for it were given by the Court in Howard *v.* Beall (23 Q.B.Div., 1). But that jurisdiction is to be exercised with the greatest caution. The Dickinson Company were not parties to the present action. At least one rule of conduct which the Court must observe in an application of this sort—though he did not say that this rule is an exhaustive one—is that if it has been proved to the satisfaction of the Court so that the Court is persuaded that the banking account which is nominally that of a person not a party to the action is really and in truth the account of a party to the action, or if it be proved in the same way that, though the account is not the account of a party to the action, yet he is so closely concerned in it that items in it would be evidence against him at the trial, and if there should be no other reason for refusing the order, then the Court may make the order asked for. But unless the Court be convinced to that extent, at least, they should not make the order. In the present case he thought that the plaintiff had established that much. But, besides that, he thought that the person making such an application as this should show to the Court that there were at least strong reasons for expecting that the account in question contained items which would be damaging evidence against the other party to the action. Here it had not been made out that there were any such items in the banking account of the Dickinson Company as would be evidence against the defendant, and he could not see why there should be any items other than those which the plaintiff already knew of. Therefore, though the Court had jurisdiction to make an order for inspection of the Dickinson Company's banking account, yet it seemed to him that, if the order were made, the Court would merely be giving the plaintiff an opportunity to try and find if there were any items which might be useful to him. The appeal must therefore be dismissed.

Lord Justice Kay concurred.—*Times.*

COMPANIES' MEETINGS AND REPORTS.

THE ALUMINIUM COMPANY, LIMITED.

The eighth ordinary general meeting of this Company was held on Monday at the Cannon-street Hotel, E.C., the Right Hon. Gerald William Balfour, M.P. (chairman of the Company), presiding.

The **Chairman** said the gross profits of the year amounted to £17,000, as against about £19,500 for last year. The difference was owing to the stagnation in the sodium trade, due to a very special cause, which was not likely to recur. That stagnation lasted throughout the winter months, but with spring the trade revived. After referring to the report, a summary of which appeared in the last issue of the *Electrical Engineer* the chairman stated that the Company had during the past year disposed of the Castner patents for the manufacture of soda by electrolysis, and stood to receive in respect of them a sum amounting in cash and shares to between £150,000 and £200,000, including £65,000 from the Mathieson Alkali Company in America—that was to say, £30,000 in cash and £35,000 in shares. In addition to that, the Company owned another important chemical invention made by Mr. Castner, the exact nature of which, at the present moment it would not be advisable to disclose. The patents for that invention in the United States of America alone had been sold for a sum of £10,000 and a third of the capital of the company which is to be formed there They had yet to dispose of those patents in England and on the Continent of Europe. Of course, from these sums there was to be deducted the 10 per cent. due to Mr. Castner under the arrangement made with him, and also any expenses in bringing out the English company, and in carrying the negotiations which have taken place to a successful issue. But after all these deductions the Board were more than justified in making the statements as to the value of the patents which were made last year. As to the criticisms and attacks that had been made on the Castner-Kellner Alkali Company, these had in no single instance come from any gentleman who had actually inspected the process as carried on at Oldbury. It would be out of place to reply to those criticisms in detail; but in reference to the high price of mercury, and the fact that the sale of mercury was more or less a monopoly in the hands of a single firm, he would point out that the new Company would not be a consumer of mercury to any considerable extent, as, after careful experiments, they had found that the waste in the course of the whole year would not amount at the outside to 2 per cent. of the mercury used and this small waste occurred in the process of handling the material, and not through volatilisation or diffusion of mercurial vapour in the atmosphere. To say, therefore that it would be dangerous to those employed was a mere mare's nest. After referring to the obligations of the Company to Mr. Castner, Mr. Balfour said that his duties elsewhere must monopolise his time and attention, and he was shortly about to withdraw from the control of the Company's affairs. It had been his good fortune to steer the Company through the most troubled waters which a public company ever encountered without foundering, and he was now able to relinquish the command after seeing the vessel safely into port. In conclusion, he moved "That the report and accounts be received and adopted, and entered on the minutes."

Sir Henry E Roscoe, F.R.S., seconded the motion, and expressed deep regret at the necessity for Mr. Balfour to withdraw from the chair which he had so ably occupied. He congratulated him on the high position he now filled, and wished him success in his great work He explained that a most satisfactory site for the Castner-Kellner alkali works had been acquired, and that arrangements had been completed for the necessary supply of salt.

Mr. Twigg asked what became of the output of caustic soda at the Oldbury factory.

The **Chairman** explained how it was they came to work at the process The Company's business had been to make sodium, and that was made from caustic soda. It was important in the manufacture of sodium that the caustic soda should be as pure as possible, and they had difficulty in getting it pure enough, and set about to try and find means of producing it themselves. The result was Mr Castner's invention. Their output of caustic soda was not distributed in the market at all, because they employed it all at their own works.

The motion was then unanimously agreed to.

The **Chairman** moved: "That a dividend of 5 per cent for the year ended June 30 last on the 'A' shares be declared, payable on the 16th inst"

Mr. Hamilton Y. Castner seconded the motion, which was carried.

The retiring directors (General Sir Andrew Clarke and Mr. Castner) were unanimously re-elected, as were also the auditors (Messrs. Broads, Paterson, and Co.).

On the motion of **Mr. Gibson**, a hearty vote of thanks was accorded the Board.

The **Chairman**, in reply, remarked that the shareholders had throughout, even in the darkest times of the Company, recognised that the directors were honestly doing their best in the Company's interest, and both the shareholders and the Board now had their reward in the increased prosperity of the Company and its hopeful prospects.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held at Winchester House, E.C., on Wednesday last, Mr. C. W. Earle, chairman of the directors, presiding.

The **Chairman**, in moving the adoption of the report and accounts, said this was the fourth consecutive report in which the Board had had to announce a reduction in the traffic receipts for the half-year, as compared with the corresponding previous six months, although every station had been in communication, and the service had been carried on as perfectly as usual, and without complaint. The question occurred as to what was the cause of

Digitized by Google

this constant reduction. No doubt the unfortunate state of the West Indies in regard to the low price of sugar had very much prejudiced the receipts. But, in seeking to be quite certain as to what was the real cause of the depreciation, he had taken some trouble to look into the traffic accounts, which were divided into two heads: first, the international traffic, the messages coming on to or going off from the Company's lines from or to other lines; and, secondly, the inter-colonial traffic between the different colonies served by the Company. He found that, whereas in 1885 the inter-colonial traffic amounted to £15,722, during 1894 it only amounted to £8,644, showing a reduction of nearly 50 per cent. The international traffic of 1894 was only about 9 per cent. less than that of 1885. It was quite fair to assume that while the Company's traffics were affected by the general decline of commercial prosperity in the West Indies, it would have affected both classes of business; but from these comparisons it appeared that it was the inter-colonial traffic that had been so much depreciated, and he was informed that the reason for this falling off was the great increase in "tramp" steamers which plied now through the West Indies. In former days the inter-colonial traffic had mainly to do with messages connected with the chartering of ships; now, no doubt, the merchants who had a cargo to send away waited for the call of some of the tramp steamers, who came in and plied for freights very much as we saw cabs "crawling" about the streets of London for fares. He had no doubt in his own mind that this had caused a great deal of the falling off in the Company's inter colonial traffic. It was fair to ask what the directors were going to do to remedy such a state of affairs. They had prospected all the West Indian shores for traffic to feed the system, and they had sent their general superintendent to various places to interview the merchants and others. These merchants, though delighted with the idea of having the telegraph laid to those places, were honest enough to say that they did not expect to find much use for it, nor would the local Governments promise a subsidy or guarantee. The directors therefore thought it better to leave the matter where it was. With regard to the accounts, there was very little, as usual, to say. The charges were almost all on the same scale and lines as they had been for years. The whole balance of revenue over expenditure was about £18,000, as compared with £16,000 last year, and, so far, might be considered fairly satisfactory.

Mr. William Andrews seconded the motion for the adoption of the report, and it was unanimously carried.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The thirtieth ordinary general meeting of this Company was held on Thursday at Winchester House, E.C., Mr. W. S. Andrews, chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report, a copy of which appeared in our last issue, remarked that exchange had averaged 9⅝, as against 9¼ for the corresponding period last year. The outlook of the Company was very much ruled by that question, and if they had a satisfactory exchange they would have little to complain of. The question of the purchase of their lines by the Brazilian Government remained very much where it had been. The authority of the Government to purchase would expire if it were not used during the present year, but the Legislative Assembly had approved an application to prolong the period, and it was confidently expected that the Bill would also be shortly passed by the Senate. There was also a subject which he would have preferred to have left untouched were it not that he was anxious that no inaccurate impression on the matter should find a lodgment in the minds of the shareholders. The latter would have seen the speech of the chairman of the Brazilian Submarine Telegraph Company on the subject of a cable *vid* Ascension and the Island of Trinidad to the River Plate. Now, the Brazilian Submarine Company had no right to lay this cable, and could not lay it during the existence of the Western and Brazilian Company, because it would be contrary to subsisting agreements. But if the purchase of the latter company by the Government were carried out those agreements were *ipso facto* determined, and the Brazilian Submarine Company would be free to do as they thought fit. At present they were not The purchase had never been improbable, and must have entered into the calculations of the Submarine Company, and there had therefore been no occasion for surprise or excitement on the subject. The Government of a nation like Brazil would, there was no reasonable doubt, be guided by the interests of the country and its mercantile community, and would treat the Submarine Company with perfect impartiality. He (the speaker) must deny that the Western Company had ever acted in an unfriendly manner to the Submarine Company. The contrary had been the case, and the interests of the companies were so far identical that it would be fatuous to adopt any other policy in that respect Whether the Brazilian Government purchased their lines or not, the Company might look forward to a share in the growing prosperity of Brazil.

Lord Richard Browne seconded the adoption of the report.

Some conversation followed on the amount expended on stationery, and an alteration in the articles of association allowing the Company after a certain period to take possession of unclaimed dividends, the **Chairman** saying the Stock Exchange would not permit that. On the subject of the smallness of the reserve fund, he also remarked that a second cable had been laid from Pernambuco to the Plate out of revenue and reserve.

Mr. W. Griffiths, who was heard with some impatience, gave notice to propose at the next meeting that there should be again two auditors as formerly. He would be pleased to act as one. The resolution adopting the report and declaring a dividend of 2½ per cent. for the half-year having been carried unanimously, the meeting ended.

HARROW ELECTRIC LIGHT AND POWER COMPANY.

The first meeting of shareholders of this Company was held at Harrow last week, Mr. C. Colbeck presiding, in the upper room of the Public Hall

The **Chairman**, in the course of his speech, said the share capital of the Company was fixed at £25,000 They had now issued 2,000 ordinary shares, and £5,000 in 4 per cent. debentures had been taken up. They had allotted 1,685 shares, which, when fully paid up, would bring £8,425, and this, with the debentures. made a total capital of £13,425, which would be shortly available. That was more than enough for their wants, so far as they could foresee, but if the directors had reason to think they wanted more, they did not anticipate the least difficulty in getting it. They had purchased a site in West-street, consisting of two cottages standing in large gardens, and seven adjoining houses, the leases of which had 64 more years to run. The whole of the property was leased from the Governors and Keepers of Harrow School, and they had paid £1,350 for it, subject to a mortgage of £1,325, which brought the total cost to £2,675. The gross rental was £198 per annum. They believed it was a fair and good bargain. Had it not been for the opposition to the transfer of the provisional order, they would by this time have been far advanced towards completion and the actual starting of the light. They had now not actually signed the contract with Messrs. Crompton and Co., but hoped to do so shortly, as there were no more difficulties in the way. They had said that the cost would not exceed £11,400 to supply 3,500 8-c.p. lamps, but they found it would not exceed £10,669—in other words, they had effected a saving of £700. Their capital was provided, and they were able to go on. They had enough custom promised from the school to live, and their financial success and dividend-paying power would depend upon how much they could manage to extend their business.

In reply to a shareholder, the chairman added that it was hoped to start the light in March next, and the proceedings closed with a vote of thanks.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Swansea.—The Corporation desire tenders for the erection of a destructor and electricity supply buildings, a chimney shaft, and a dust destructor, with furnaces and boilers. Particulars will be found in our advertisement columns.

Punta Arenas (Chili).—Tenders will be received until December 5 for the manufacture and laying of a submarine telegraph cable from Puerto Montt to Punta Arenas. The conditions and specifications may be consulted in the Chilian Legation, Member's-mansions, 36, Victoria-street, S.W.

Huddersfield.—Tenders are invited for the works required in erection of a mill, and include an engine-house, boiler-house, chimney, dynamo house, etc. The specifications may be obtained of Messrs. John Kirk and Sons, architects, Huddersfield and Dewsbury, from 14th to 28th inst., on which latter day sealed tenders are to be sent in to them.

Cardiff.—The Technical Instruction Committee desire tenders for the electric lighting of the new buildings in course of erection in Dumfries-place. Further particulars may be obtained on application at the college buildings, Dumfries-place, Cardiff. Sealed tenders, endorsed "Electric Lighting," must be delivered to the secretary, Mr. Jenkins, at his office not later than the 28th inst.

Paris.—The Municipal Authorities invite tenders by November 21 for the supply of two dynamos for the municipal electricity works. Conditions from L'Hôtel de Ville, Paris. Further, the Direction Générale des Postes et des Télégraphes invites tenders by November 28 for the supply of 46,280 creosoted telegraph poles in eight lots. Requests for admission to the adjudication before November 18. Specifications at rue de Grenelle, No. 103 (division du matériel et de l'exploitation électrique, 3E bureau).

Warrington.—The Cheshire Lines Committee, among other stores to be supplied in 1896, desire tenders for telegraph materials, instruments, and wire. Patterns can be seen and specifications, with forms of tender, obtained upon application to Mr. Saxon Barton, storekeeper, Cheshire Lines, Warrington, and intending contractors are requested to particularise the stores for which they wish to tender. Sealed tenders, endorsed "Tenders for ——," to be in the hands of Mr. Glegge Thomas, secretary, Central Station, Liverpool, addressed Cheshire Lines Stores Department, Warrington, by 10 a.m. on 30th inst.

Handsworth.—The Urban District Council are prepared t receive tenders for an installation of fire-alarms to firemen's house and telephonic calls to out-stations. Plans and specifications prepared by Mr. W. H. Whitehouse, electrical engineer, may be seen at the Surveyor's Offices, Council House, Handsworth, where form of tender and all information may be obtained from Thursday, the 14th, to Tuesday, the 26th inst., upon which latter day

Digitized by Google

sealed tenders must be delivered at the above office, endorsed "Tender for Electrical Fire-alarms, etc." The tender of any firm paying less than the standard rate of wages will not be considered.

Windsor.—The Corporation invite proposals for taking over and working their electric lighting order. All proposals to include the erection and maintenance of a generating station upon a specified site, laying down mains, and necessary equipments, with a constant supply of electricity for lighting purposes in the area, as stated in above order, the Corporation reserving to themselves the right of taking over the plant at the end of a term of years, this term to be stated in the tender. The order can be inspected and full particulars obtained on application to the town clerk, Windsor, to whom sealed tenders, endorsed "Electric Lighting Tender," must be sent by January 1.

Blackburn.—Tenders are invited for the following, for the Corporation: Section B, steam alternators and motor alternator; Section C, switchboard and engine-room connections; Section D, street transformer-chambers, transformers, etc. Conditions of contract, specifications, and forms of tender, may be obtained at the offices of Mr. E. M. Lacey, 10, Delahay-street, Westminster, on payment of £3. 3s., which will be returned on receipt of bona fide tender. Applicants should state which section they desire to tender for. Tenders, sealed and endorsed "Electricity Extensions," must be delivered at the office of Mr. Robert C. Fox, town clerk, Town Hall, Blackburn, by 30th inst.

York.—The directors of the North-Eastern Railway are prepared to receive tenders for the undermentioned articles, in such quantities as they may require during the six months ending June 30, 1896, delivered carriage paid at the company's telegraph stores at York—viz., (1) telegraph apparatus, (2) telegraph wire and line stores. Payment for each month's delivery will be made at the end of three clear months, or in cash less 2½ per cent. discount Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent in to the secretary at York, sealed and marked "Tender for Telegraph Stores," not later than noon on November 26.

Derby.—The Midland Railway Company, among other stores, invite tenders for the supply of (10) telegraph instruments; (10A) galvanised telegraph stay-rods, bolts, etc; and (10B) telegraph and signal wires. The patterns will be ready for inspection at the General Stores Department, Derby, and forms of tender may be had on application being made to Mr. G. Morrall, Derby, care being taken to give reference to the particular contract (by the above numbers) for which it is proposed to tender. Tenders, addressed to the secretary of the General Stores Committee, Midland Railway, Derby, and endorsed "Tender for Stores," must be sent so as to be received by 9 a.m. on 19th inst. Mr. James Williams, secretary, Derby.

Durban (Natal)—The Corporation of Durban desire tenders for No. 40 cast-iron service-boxes for connections from concentric mains, No. 120 cast-iron service-boxes (or handholes) for house connections, No. 60 cast-iron junction-boxes for arc lamps, No. 70 cast-iron manhole frames and covers, and No. 60 ornamental cast-iron arc pillars, 25ft. high. The manufacturer must submit with the tender the designs of what he proposes to supply. Duplicate conditions, specification, and bill of quantities may be obtained from the consulting engineer, Mr. W. H Radford, C.E, Pelham-chambers, Nottingham, on deposit of £2. 2s, which will be returned on receipt of bona fide tender. Sealed and endorsed tenders must be delivered at the office of Messrs. Webster, Steel, and Co., 5, East India-avenue, Leadenhall-street, London, E.C., agents to the Durban Corporation, by 27th inst.

London, S.E.—The Metropolitan Asylums Board desire tenders for the execution of wiring and other work in connection with the electric light installation at the Brook Hospital and Ambulance Station, Shooter's Hill, S E. Copies of the specification, form of tender, conditions of contract, and of the drawings which have been prepared by Prof. Kennedy, LL D, F R.S., 14, Old Queen-street, Westminster, can be obtained of Mr. T. Duncombe Mann, clerk, Norfolk House, Norfolk-street, Strand, W.C., on and after 4th inst., upon depositing gold or Bank of England notes to the value of £25, which will be returned only to those who send in a bona fide tender, and who return the drawings, specification, and conditions of contract Tenders which will only be received on the lithographed form supplied by the Board, must be sealed and endorsed "Tender for Wiring, etc.," Electric Light, Brook Hospital," and must be delivered at the offices of the Board by 11 a.m. on 18th inst. Unless the tender be accompanied by the specification, conditions of contract, and the drawings, it will not be considered.

RESULTS OF TENDERS.

Tunbridge Wells.—The Lighting Committee have accepted the tender of Mr. Every for brackets to be attached to the arc lamp-posts at 17s. 9d. each.

St. Marnoch's (co. Dublin).—The contract for the electric lighting and pumping plant at St. Marnoch's, co. Dublin, to the specification of Mr. Morgan Williams, C.E., has been placed with Messrs. Edmundson, Limited, of Dublin. The motive power is to be derived from oil-engines.

Cheltenham.—The Corporation have accepted the tenders of Messrs. Siemens Bros. and Co. for a new switchboard at an inclusive price of £165 fixed and connected up complete, and for a regulating resistance for the new machine at £12. 10s. The electrical engineer reported that he was not yet prepared to report on the tenders for arc lamps and transformers as the tests were not complete, and it had been necessary to obtain modified tenders or the transformers.

BUSINESS NOTES.

Aston Manor (Birmingham).—A new electric light plant for the baths and public offices is proposed.

Bowness (Cumberland).—The Urban District Council have made a two years' contract for electric lighting.

Tilsit.—The Allgemeine Elektrizitätsgesellschaft purpose constructing an electric tramway at Tilsit at their own cost.

Leeds—Mr. R. Gaudin, of the British Traders' Mercantile Agency, has been appointed Russian Vice-Consul for Leeds.

Rotherham—The Town Council have appointed a committee to make enquiries on the subject of electric lighting and tramways.

Dewsbury.—Five additional installations in shops are reported, including eight arc lamps. Mr. R. Turner is responsible for the work.

Plymouth.—The Town Council have decided to appoint a special electric lighting committee in place of the present small sub-committee.

Derby.—The Town Council have resolved to apply to the Local Government Board for sanction to borrow £4,146 for electric lighting purposes.

Zurich.—The new academy of music is to be connected to the alternating-current system of the town of Zurich, Pollak rectifiers being brought into use.

Sandwich.—Negotiations are being carried on by the town surveyor with the landowners for the construction of a tramway to the seaside, a distance of two miles.

Brighton.—A special meeting of the Brighton Town Council has been convened for Saturday next to further consider the Rottingdean electric railway question.

Sale (Cheshire).—The clerk to the District Council has reported that he had received no reply to his communication to the Ashton Urban Council regarding the electric lighting.

Telegraphs in Mashonaland.—The telegraph line between Umtali and Beira has been opened, thus completing communication overland from Cape Town to the East Coast.

Metropolitan Asylums Board.—The Brush Electrical Engineering Company have been added to the list of selected firms invited to tender for work for the Brook Hospital Committee.

Walsall.—The General Purposes Committee have recommended the purchase of two additional transformer armatures for the electricity supply works from Parkers, Limited, at a total cost of £224.

Weybridge.—The Urban District Council have appointed a committee to confer with Mr. Martindale as to the transfer of the provisional order from the Weybridge Electric Supply Company to the Council.

Electric Tramways in Persia.—Herr Felix Moral, a German subject, has obtained a 90 years' concession for a steam or electric tramway, about 10 miles in length, from Teheran to the villages north of the city.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended November 10 amounted to £1,063, as compared with £892 in the corresponding week of last year, being an increase of £171.

Vienna.—The Akkumulatoren-Fabrik Aktiengesellschaft purpose introducing as an experiment lead-accumulator cars on the line between the Franz Joseph railway station, the Quai, the Ringstrasse, and the Porzellangasse.

Dover.—The Corporation have passed a resolution applying to the Board of Trade for the necessary powers to enable them to construct electric tramways throughout the borough, the majority of the main streets being scheduled.

Victoria Electric Railway and Lighting Company, Limited.—The numbers have been published of the 5 per cent. first mortgage debenture bonds, amounting to £1,000, drawn for repayment on January 2, at the rate of £105 per cent.

Johannesburg (South Africa).—The Sanitary Board have decided to use the Brockie-Pell arc lamp for the lighting of the streets, and an order has been placed with Messrs. Johnson and Phillips, London, for upwards of 50 lamps.

Monmouth—The result of the municipal election is taken as showing that the ratepayers are favourable to the proposed electric lighting scheme, the retiring councillors who supported the scheme having been re elected by substantial majorities.

Newport (Monmouth).—The Town Council have decided, subject to the sanction of the Local Government Board, that they will purchase for the sum of £1,000 the spare electrical plant which had been hired from Messrs. Fowler and Co., Leeds.

Newcastle-on-Tyne.—The Town Council have passed the formal resolution for promoting in the ensuing session of Parliament a Bill which, among other matters, gives powers to construct tramways and work them by electricity, petroleum, or other motive power.

Wolverhampton.—In their annual report the Lighting Committee refer at some length to the introduction of the electric light, and state that they have every reason to believe that during the ensuing season the business of the undertaking will be largely developed.

Dundee.—At a meeting of the Guildry to appoint representatives on the Harbour Trust, there was some discussion on the desirability of an electric tramway to the eastern jetties. It was understood that the trustees would take the matter into consideration.

Digitized by Google

Christiania.—The proprietors of the Roros Copper Works are reported to have placed a contract with a firm in Christiania for a large electrical plant, it being intended not only to light their mines by electricity but also to operate all the mining machinery electrically.

Agency. — Messrs. Musgrave Bros., hydraulic and general engineers, of Leeds, have appointed Messrs. Julius Harvey and Co., engineers and merchants, of 11, Queen Victoria street, E.C., as their representatives for London and district for the home and foreign trade

Lambeth (London).—A meeting has resolved that the members of the Vestry present should be asked to support an application to the Board of Trade for an extension of time in which to consider the question whether the Vestry should or should not adopt electric lighting in the parish.

Ripon.—The Dean and Chapter have instructed Messrs G. Harrison and Co., of Ure Bank Works, to proceed with the experimental electric lighting of the cathedral, and they hope to have the generating machinery and two Brockie-Pell arc lamps at work early next month.

Yarmouth —The report to the Town Council on electric lighting shows that during the past month £104 5s. 5d. was earned beyond the cost of production, from which had to be deducted repayment of capital, interest, depreciation, rates, and taxes, which amounted to between £85 and £90 per month.

Taunton.—The municipal electrical engineer has stated that the demand for the electric light was steadily increasing, and they had added 140 16 c.p. lamps during the quarter. The maximum load on the private lighting circuits was about 20 per cent. greater now than it was at the corresponding quarter of last year.

City and South London Railway.—The returns for the week ended November 10 were £1,009, compared with £969 for the corresponding period of 1894, being an increase of £40. The total receipts for the half-year 1895 are £16,658, compared with £16,719 for the corresponding period of 1894, being a decrease of £61.

Belfast.—At the meeting of the Electric Committee, we understand that a complaint was made by the engineer (Mr. M'Cowen) with regard to the working of the present gas-engines, and as these engines had been already tested by Prof. Kennedy the committee decided that his attention should at once be drawn to the matter.

Alderley (Cheshire).—The Urban District Council have received a letter from Mr. Clirehugh with reference to the transference of the electric lighting provisional order to a private company, suggesting a few alterations on technical points in the agreement of purchase which had been drafted. These were practically agreed to.

Dublin.—Dr. Wm Carte, Messrs. William M. Murphy, John R. Wigham, and William Anderson, directors of the Dublin tramways, have returned from the United States, where they have been to study the various methods of street transit, especially electrical ones in use, with a view to the selection of an appropriate system for Dublin.

Telephones in Hampshire —The County Council have received a committee's report to the effect that the National Telephone Company had agreed to considerably reduce the rents of the existing telephones, and that new connections would be made at Aldershot, Basingstoke, Cosham, Fareham, Farnborough, and Lyndhurst.

Ashton-on-Mersey.—The Urban District Council have adopted a resolution to put into force the Electric Lighting Provisional Order of 1883 and 1888, as to an agreement come to between the Council and the Altrincham and District Electric Supply Company, Limited, for the supply of electric light in the district covered by the Council.

Chelsea.—Specifications are being prepared for the wiring of the new workhouse buildings in Sydney-street for electric light. The Chelsea Electricity Company have written to the Guardians stating that their sliding scale for current would be 5d. per unit, 1d. less than the usual charge, and a further reduction when warranted by an increased consumption.

Timperley (Cheshire).—Mr. Bell has reported to the Rural District Council having examined the proposed application to supply electricity to Timperley, and he saw no objection, provided the road were made good again subject to the approval of their surveyor. No opposition was offered by the Council to the proposed application for a provisional order.

Aberfeldy.—An interesting experiment has taken place on Loch Tay. Trial trips have been made with the "Mystery," an ordinary keel boat 16ft. in length, built at Clydebank, and purchased by Mr. John Macdonald, of Beechwood Cottage, Strathtay, who has fitted it with his patent electric battery and electrical gear. The boat ran the nautical mile in nine minutes.

Fulham.—At a meeting of the Electric Lighting Committee of the Fulham Vestry five engineers were interviewed—viz, Messrs. R. Hammond, T. W. Baker, E. Manville, F. H. Medhurst, and G. Wilkinson. Mr. Medhurst obtained the appointment of consulting engineer to the Vestry, the final voting being: Mr. Medhurst, six votes; Mr. Manville, three votes.

Coventry.—Posts and wires are now being erected for running the tramway from Coventry to Bedworth on the overhead system. A trial trip over the new tramways from the depôt at Foleshill to the Coventry station has been made by one of the new electric cars. The system is the Thomson-Houston overhead wire system. The car was illuminated by electricity, and the run was successful.

Southampton.—In reference to a paragraph in our last issue, it should have been stated that the Dock Estate has been lighted since 1893, and the new electric lights referred to are necessary in consequence of extensions at the new dock. Moreover, the quays belonging to the Harbour Board are lighted electrically, so that the Mersey Dock Board can hardly claim priority in this matter.

Proposed Electric Railway in Derbyshire.—Plans of the proposed new light railway from Derby to Ashbourne have just been completed. Levels of the roadway have been taken, and the usual parliamentary notices will be published this week. The Bill for the construction of the new line, which is to be worked by electricity, will be deposited in Parliament at the earliest possible moment.

Devonport —About two years ago the dockyard officials suggested that the internal portions of ships in course of construction should be lighted with electricity. Their Lordships gave authority for using the spare dynamos and lamps in the dockyard for this purpose, and the results have been so satisfactory that the Admiralty have decided to replace the temporary gear by permanent plant of the most modern type.

Bangor (North Wales).—In spite of the resolution of a ratepayers' meeting and several numerously signed petitions, the Town Council are going on with their electric lighting scheme. A local paper says the dispute has now reached a stage at which it is not so much a question of whether the electric lighting scheme is good or bad, but whether the Council is to set at defiance the predominating wish and determination of the burgesses.

Glasgow.—The directors of the Glasgow Chamber of Commerce have received a letter from the Postmaster-General regretting delay, due to the recent unforeseen increase of telegraphic business, in the transmission of messages between Glasgow and London. The Postmaster-General, the letter added, was making provisional arrangements to improve the service. The Chamber, however, regarded the communication as unsatisfactory, there still being great delays.

Streatham.—One of the surveyors of the National Telephone Company has attended a meeting of the District Board and asked permission to lay a telephone cable under the footpath at Streatham-hill. At present, he explained, communication between the City and Streatham has to be carried on by way of Croydon. The Board had offered to allow a cable within a disused sewer, but there were objections to this. The Board granted the request of the company.

Islington.—The Vestry have decided that their new underground conveniences to be constructed near Archway Tavern shall be lighted by electricity. The completion of the loan to the Vestry for the purchase of land for the electric lighting station has been reported by the Finance Committee of the London County Council. The Vestry have purchased a piece of land from the Great Northern Railway Company for an electric lighting siding at Holloway, at a cost of £257.

Mevagissey (Cornwall).—Mr. James Kemble has reported to the Parish Council on the progress made with regard to the formation of an electric light company. About £300 more remained to be raised to complete the necessary capital, and if the Council would give the promoters a fortnight to issue a prospectus, they would probably be able to give the Council definite information, and proceed at once with the lighting of the town This was agreed to.

The International Electric Company.—We have received from this Company, whose address is 55, Red Cross-square, Barbican, E.C, a copy of their new catalogue. It is a well got up volume of 200 pages, and deals with electric bells, indicators, switchboards, telegraph instruments, electro-medical apparatus, microphones, and telephones, the firm calling special attention to the last section. It is copiously illustrated, and provided with an index to facilitate reference.

The New Regulations for Electric Lighting.—The draft of the revised regulations for securing the safety of the public and for ensuring a proper supply of electrical energy, which have been prepared by the Board of Trade, will be considered at a meeting of representatives of municipal corporations, electric lighting companies, and others interested in electric lighting to be held at the Westminster Town Hall on Tuesday next, the 19th inst., Sir Courtenay Boyle, K.C.B., presiding.

Copper.—The copper circular of Messrs. D. Houston and Co., of New York, states that the actual consumption of the metal in America continues on a large scale; but manufacturers seem to be pretty fully stocked, and activity in copper is not anticipated until the close of the year. Messrs. Houston expect that the development of electric traction in Europe will soon be an important factor in the future of copper consumption. They also refer to the proposal to construct 84 miles of electric tramways in Japan.

Neston (Cheshire).—The District Council have received a report from Mr. O. March, London, on an electric lighting scheme. The report stated that the conditions were favourable, gas—not in the hands of the Council—being dear and steam coal cheap, but against this was the fact of the district being scattered. Under the scheme the alternating current would be adopted and the district divided into three circuits—Neston, Little Neston, and Parkgate. The plant would cost £6,000. It was decided to call a meeting of ratepayers to consider the scheme.

New British Electric Installation Company.—It is stated that the official receiver (Mr. Luke J. Sharp) has laid the whole of the facts arising out of the bankruptcy of the New British

Digitized by Google

Electric Installation Company (Worcester) before the Board of Trade, and that body has ordered a public examination before the judge of the county court (Sir Richard Harington), unless power is obtained from the Lord Chancellor to delegate the duty of presiding at the examination to the registrar. It is understood that the judge will make the necessary application to the Lord Chancellor.

J. C. Howell, Limited.—Mr. Sidney F. Isitt (liquidator), of 6, Old Jewry, E.C., writes: "The paragraph appearing in your edition of the 8th inst. has been brought to my notice. I beg to state that the liquidation has been brought about, by the wish of the shareholders generally, for the purpose of disposing of the business and assets of the Company. Under the liquidation the shareholders have consented to my disposing of the same to Mr. J. C. Howell as from the 1st inst., and negotiations are in progress for this purpose. The liabilities of the old company will be discharged not by me, but by the purchaser."

City of London.—Dr. Sedgwick Saunders, the medical officer of health, in his report to the City Commission of Sewers says that the extension of installations of electricity has marked a new era of sanitation, and much benefit must accrue to the moral and physical condition of the employés in large commercial establishments who had hitherto been condemned to work long hours by day and night in gas-heated, ill-ventilated basements. At the end of the year, there were nearly 3,000 private consumers of electricity, using upwards of 136,000 incandescent lamps, and 483 electric lamps were now placed in the principal streets, displacing 1,338 gas lamps.

Cheltenham.—The Town Council, acting on the report of their electrical engineer that it was very advisable, in order to economise labour and time and to minimise liability to breakdown, that all the sub-stations should be connected by telephone to the Manchester-street sub-station, at an estimated cost of £100 to £110, have resolved that an order, provisional upon the consent of the Local Government Board being obtained to the further loan of £10,000, be given for the length of cable required for the extension from Cambray to the Belle Vue; and that telephone wires be laid down with all new cables between the Manchester-street sub-station and the other sub-stations.

Crompton Company of Australia.—In the Chancery Division Mr. Justice Stirling was asked, in the debenture-holders' action of Whiffen *v* the Crompton Company, Limited, of Australia, to continue the appointment of the receiver and manager. It was stated that there was every prospect of the Company's business - which was now being carried on at a profit—being sold either to another company to be formed for the purpose of acquiring it, or to one of the established companies in England which might be desirous of extending its operations in Australia. The agent of the receiver was now on his way to this country with a view to assisting in the negotiations. His Lordship extended the appointment for a day fortnight.

Bristol.—Messrs. King, Mendham, and Co. have found their present premises of the Western Electrical Works in Narrow Wine-street inadequate to the carrying on of their business and have taken new premises at 10, Victoria-street. Extensive alterations are being made to adapt these premises to the requirements of a manufacturing business, and they will shortly be opened with a large stock of fittings and apparatus for experimental use, as well as for the practical application of electricity. The Stapleton Urban District Council have appointed a committee to visit Bath and Taunton, as well as Bristol works, with a view to deciding on the adoption of the electric light. They have also asked if the Barton Regis Guardians will take the electric light at the workhouse.

Edinburgh.—The Leith Corporation have proposed to confer with the Edinburgh Town Council as to the best mechanical means of working the tramway system. On the motion of Mr. Mackenzie, convener of the Electric Lighting Committee the Town Council have made a remit to the Lord Provost's Committee with powers to consider the advisableness of adding another engine and dynamo to the electric light station, as unless something were done immediately they might soon have to refuse customers. Mr. Cranston suggested that if the price of electric power during the day was made the same for lighting as for motors—viz., 3½d. per unit—there would be a great increase of consumers who would use it for show purposes. The Lord Provost said this was the first winter of the light, and the committee should have time to look about a bit.

Paisley.—The Town Council have received a letter from Dr. Bottomley, in which he stated that he would be glad to act as consulting electrical engineer in the matter of the electric lighting of the Town Hall and the museum, and that his fee for drawing specifications etc., and superintending the work and testing it when complete, would be £105, with travelling expenses, if the work in the two places should go on simultaneously. The clerk was instructed to write Dr. Bottomley accepting these terms. A letter has also been received from the engineer and manager of the Caledonian Electric Supply Company, Limited giving notice that his company intend to apply for a provisional order for the electric lighting of the burgh and asking that before coming to a decision on the matter the Council would give his company an opportunity of submitting a copy of the terms they would be prepared to offer.

London County Council.—The chief officer of the Fire Brigade has asked that the system of telephonic apparatus at the chief station may be made uniform with that at the superintendents' stations. The Post Office has intimated that the charge for making the necessary alterations and providing and maintaining the necessary new switching apparatus is estimated at £67. 10s. per annum, subject to the same stipulations as were agreed to when similar apparatus was fitted at the superintendents' stations. Annual charges amounting to £9 in respect of apparatus which will be dispensed with will cease, and consequently the estimated net additional annual charge will be £58. 10s. The committee have recommended that, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, the necessary expenditure in connection with the rearrangement of the telephonic apparatus at the chief station be sanctioned.

Tunbridge Wells.—The Mayor has reported to the Lighting Committee the result of his personal inspection of the machinery at the central station, and the engineer has submitted his tests, and the committee resolved that the machinery be not accepted, but they would be ready to consider any communication from the contractors. Mr. Preece's attention was called to the condition of the gas-engine, and he was requested to report upon the machinery as soon as possible. The Works Committee wrote enquiring at what rate the current could be supplied for motive power, and 3d. per unit was fixed. Mr. Nash was appointed assistant engineer at a commencing salary of £90. Extensions of the electric mains in Vale-avenue, Crescent-road, Lansdowne-road, and Pembury-road were decided upon. A resolution from the Tradesmen's Association as to the hours of supply of current was received, and it was decided to supply the current for longer hours pending a continuous supply.

Ayr.—Bailie Ure has given notice that he will move at the Town Council, "That a small committee be appointed to consider the advisability of adopting tramways between Ayr and outlying districts to be driven by electric or other motor, to enquire and report." A minute of the Lighting Sub-Committee of the Police Commissioners stated that it was decided to place an electric lamp in the centre of the Old Bridge, another at the corner of George-street and Wallace street, and a third at the corner of George-street and Content-street. Mr. Grant asked the convener of the Lighting Committee if the meters were not ready now. Some of those who were having the electric light introduced to their premises would like to have the work finished, whether the light was turned on or not. Bailie Ure said their present intention was that they would be able to give the light to the library and the Town Hall about the beginning of December, but he would not advise the streets being lighted till the end of the month.

Harwich.—The Public Health Committee have received from the Town and Village Electric Light and Power Company, Limited, the following alternative proposals: (1) to provide for the Corporation a complete installation of electricity for power as well as for light, and to take payment therefor by instalments extending over 40 years, the sum from time to time remaining unpaid bearing interest at 3 per cent; or (2) to take over the power of the Corporation under the Harwich electric lighting order upon the following terms—viz.: (*a*) to provide the installation without any cost to the borough, and to enter into a contract for the supply of electricity for public lighting for the term of 14 years, at the cost of 4½d. per unit (*i.e.*, the equivalent to 2s. 3d. per 1,000ft of gas); (*b*) to pay the Corporation £300 by an allowance of a 10 per cent. discount off each quarter's account for public lighting until the whole of the £300 is absorbed. The committee, after consideration, recommended the Town Council to accept the second proposal, and after a long debate a resolution to that effect was carried by the casting vote of the Mayor.

Runcorn.—The Electric Lighting Committee have recommended that the Urban District Council should apply for a provisional order for electric lighting. Dr. Gastaldi, in moving the adoption of the report, said that with a capital of £11,000 the Council would be enabled to provide 2 000 lights of 16 c.p. The cost of interest on a sinking fund of £11,000 would be £750. The cost of providing the electric light sufficient for the lighting of the public streets and also for private individuals would be £800 per annum, making a total of £1,550. This would be the total expenditure incurred. If they used 500 lights for the streets they would still have 1 500 to sell, and supposing they sold them at the rate of 10s. a lamp per year they would realise the sum of £750. Adding to that the sum of £1 000, which was at present paid by the Council for lighting the streets and public buildings, they would have a revenue of £1 750. Deducting from that the expenses of £1,550, they would have a balance of £200. After considerable discussion, an amendment was carried by one vote referring the matter to a committee of the whole Council for further consideration.

Swansea.—The Corporation's tramway scheme provides that the tramway company is to have a lease for 21 years, and at the expiration of that time its rights will cease and the rights of the company will pass to the Corporation, who will be at liberty to lease the system to whoever they choose. The conditions are—assuming that the cars are in future to be worked by electricity supplied by the Corporation from the electric lighting and destructor works about to be erected—that the Corporation advance to the tramway company £10,000 to enable it to pay off its debenture-holders, and £22 000 to enable it to purchase say. 20 motor cars, etc., at about £1,000 each. In addition to that the Corporation advance £20,000, to be expended on the putting of the line into a proper state, erecting posts, etc. For this £52,000 the company pay interest at the rate of ½ per cent. more than the Corporation would have to pay for it, and with respect to the £20,000 the company would, by means of a sinking fund, repay it in 21 years, and with respect to the £32,000 the company would by the same means repay it in 30 years. The company expect much economy in the substitution of electric traction. It is estimated that if the Corporation supply the tramway company with electricity at 2d. a unit, 4d. per car mile would cover the cost of traction and repairs

Digitized by Google

against 8d. at present paid. The lines are to be kept in repair by the Corporation, which will have power to charge the company with the actual cost. The scheme has been approved by the Town Council, who have decided to promote a Bill in Parliament next session to carry it out.

Cardiff.—Mr. B. Eustace Good, of Cardiff, writes to a local paper as follows: "As a tentative suggestion, I would propose that the Corporation, upon the purchase of the tramways, should convert the Canton to St. Mary-street route into an electric line, the power being obtained from the Corporation electric light station, which is in comparatively close proximity; the steam and electrical plants being necessarily supplemented for the purpose. As a result of enquiries, I find that the approximate cost of the conversion of the Canton-St Mary-street line would not exceed £20,000. The money expended upon the construction and equipment of the Leeds Roundhay Tramway (5¼ miles) was £23 000 According to "Duncan's Tramway Manual," the average cost of horse tramways is 9·50d. per car mile; that of electrical lines 5 00d. Little fear, therefore, need be entertained but the line would pay from the first. Glasgow has unmistakably proved that tramways should, and can, be profitably worked by a municipality, with cheaper fares, faster travelling, and better accommodation. I have clearly shown that Cardiff, by adopting electric traction, can even improve upon Glasgow's magnificent triumph of municipalisation."

British Electric Traction (Pioneer) Company, Limited.—This Company has been formed, with a capital of £100,000 in £10 shares, to take steps for the development of electric traction in the United Kingdom and elsewhere on systems which have already proved successful in the United States and on the Continent of Europe. The Company will also investigate and test new and improved methods, and in due course will form a larger company with adequate capital. The prospectus states that the Company is not committed to the use of any particular system, but will aim at developing electric traction in the most approved ways and according to the requirements of each locality. Some important inventions and proposals relating to electric traction have been, it is added, submitted to the directors, and will receive early attention. The Electric and General Investment Company, Limited, have agreed to pay all expenses of the Pioneer Company up to allotment and to give its assistance in the launching of the proposed larger concern. The profits of the Pioneer Company will depend, it is said, upon the successful issue of the capital of this larger company. The subscription list opens and closes to-day (Friday).

Birmingham.—Mr. Alfred Dickinson, of the Birmingham Central Tramways, writes to the Birmingham *Daily Post* respecting the proposed electric trams for Nechells: "Will you permit me to point out to Mr Frederick J. Colbeck, and those people who think with him, that it is not proposed, in the equipment of the Nechells route to disfigure the street with a network of wires, similar to Coventry and elsewhere, as suggested by him. It is proposed simply to substitute for the existing lamp posts (on one side of the road only) combination poles—that is, a pole which will act as a support for the ordinary street lamp and for the trolley wires. There will be no cross-wires from one side of the street to the other. but simply a small wire, a ¼in. in diameter, running parallel with the track, and not coming out from the footpath over the road more than an average of 12in. practically running over the gutter. Many people seem to think that it is proposed to introduce something in the way of an experiment I should like to point out that in America and on the Continent of Europe there are over 600 distinct electric tramways, operating at least 15,000 motor cars, on 5 000 miles of street lines; that last year over 70 million car miles were run, and over 770 million passengers carried."

Stratford-on-Avon.—With reference to the proposed Stratford-on-Avon railway, Mr. T. C. Sharp, of Birmingham, writes to a local paper: "Your correspondent, 'A Supporter of the Scheme,' in suggesting that the Warwickshire County Council should construct a light railway on the site of the above, in the event of the undertaking being abandoned, offers a most important consideration for the farmers in the vicinity of the proposed railway. I do not know what the estimate for the carrying out of the present scheme is, but the sum would not be less than £250,000, and for this outlay the agriculturist could be accommodated with 125 miles of tramways by the sides of the highway in a similar manner to those adopted in Belgium, in place of about 22 miles, the length of the proposed line. It cannot be too clearly understood that the chief object of the new main lines now contemplated is to facilitate competition for through traffic, more than for the benefit of the farmer. Lord Winchilsea's scheme will do much to lower the present prohibitive railway rates for agricultural produce, and his proposal to form a co operative association for farmers will. in addition to being the best organisation for their benefit, also ultimately convince the British agriculturist of the urgent need of some cheaper means of conveyance for their stock and produce than the present railways can possibly afford."

Torquay.—The Electric Lighting Committee of the Town Council have recommended that the necessary steps be taken for carrying out the first report of Mr. W. Trentham, M.I.M.E, with respect to providing a central station with plant and machinery under the Bath Saloons, and distributing mains for lighting the compulsory area referred to in the Torquay Electric Lighting Order, 1891, and that application be made to the Local Government Board for sanction to borrow £18,000 required for the purpose. Mr. Kerswill, moving the adoption of the recommendation, said the time had come when Torquay must take action in the matter and introduce the new light. No doubt they had gained something by waiting, but they ought not to wait longer. Over 80 towns in England had introduced the light, and 42 local authorities had kept the power in their own hands. Towns adopting the light had shown a profit in the first year, and considerable profit after working for two or three years. Mr. Trentham had since written that the details of his scheme A might be modified a little with advantage. In going carefully into the tabulated results of electric light working in various towns, he found that he had overestimated the working expenses and slightly underestimated the revenue. At 6d. per unit the revenue would amount to £3,300, or, with arc lamps, to £3,600; whilst the working expenses would be £1,160, and, adding interest at 6 per cent., £2,292, leaving a net profit of £928, not allowing any revenue from meters, motors, or cooking apparatus. The fact that private companies were applying for powers for lighting Torquay with electricity was sufficient to warrant the Town Council in introducing the light. Ultimately the subject was referred to a committee of the whole Council.

Bury St. Edmunds.—The report of the committee appointed to consider the question of the advisability of lighting the town by electricity has been laid before the Town Council. The report showed that three meetings were held, and at the first of these Mr. Turner was appointed chairman. After some discussion it was agreed that before bringing the question of electric lighting before the Council an expert be asked to give a report as to the advisability and prospect of a favourable financial result. At the second meeting, held on October 25, letters were read from several electricians offering to visit the town and report on the subject of electric lighting, amongst them being Mr. Medhurst, who offered to attend a meeting of the committee at his own expense, and to give a full report for an inclusive fee of 25 guineas. This was agreed to, and Mr. Medhurst attended an adjourned meeting, and explained a proposed method of public lighting and the probable capital expenditure and income, and it was resolved the Council be recommended to engage Mr. Medhurst to prepare a report and specification upon the electric lighting of the town at a cost of 25 guineas Mr. Turner, in moving the adoption of the report, said, as they had before them a very able report of the scheme of electric lighting at Tunbridge Wells, the committee had thought it advisable to write to Mr. Preece, and he (Mr. Turner) had visited Tunbridge Wells The work there had been very excellently done, but in his opinion a great deal more money had been spent than need have been. Mr. Preece had offered to come down and advise them and to prepare a report and scheme for the sum of 50 guineas. A discussion followed, Mr. A. J. Hooper at once raising the question whether councillors who were shareholders in the gas company could speak and vote The town clerk gave it as his opinion that they could do so. Ultimately it was unanimously agreed that 50 guineas be substituted for 25 guineas in the report, and the last clause was altered by the deletion of the name of Mr. Medhurst and the substitution of the word "expert" and the report was then adopted. It was also decided that telephonic communication should be established between the officers of the fire brigade and the police station, with electric bells and wires from the police station to the residences of some of the men, and that the National Telephone Company should do the work.

Blackpool.—The Electric Lighting Committee of the Corporation is now to consist of all the members of the Council. It has been decided to greatly improve the tramway service in the borough. Powers have already been obtained to construct a line by Cow Gap-lane and Whitegate-lane, and it has been now agreed to ask for further powers to lay down a line along the northern section of the Promenade to the end of Claremont Park returning by way of Dickson-road and Warbreck-road to the Talbot-road Station. Another new line is to be made *vid* Talbot-road and New-road to the cemetery, and it is proposed in each instance to employ electric traction. The Electric Lighting and Tramways Committee have applied to the Board of Trade for consent to the Corporation working the Lytham-road tramways, south of Station-road, by electrical power on the accumulator system, and have received it. Two letters were also read from the Board of Trade in reference to the recent accident in the electric lighting street boxes, and a memorandum by Major Cardew, R E. the electrical adviser of the Board. The town clerk was instructed to reply that the Corporation propose adopting the recommendations of Major Cardew. A letter was read from Mr. B Sykes, on behalf of a proposed company for constructing a tramway from Blackpool to Fleetwood, applying for the consent of the Corporation to the company constructing tramways in the borough, north of Talbot-road railway station and through Claremont Park to the northern boundary of the borough, or for a statement on what terms the Corporation would lease to the company any lines constructed by the Corporation in the direction indicated. It was resolved that as the Corporation are about to apply for further powers for their tramways, and for the construction of new tramways in the northern portion of the borough, the Corporation are unable to accede to the requests contained in the letter. Resolved, the Corporation apply to Parliament in the ensuing session, either by Bill or by provisional order, for the laying of a double line of tramways in Station-road; also for the laying of tramways along Dickson-road, Warbreck road, to the Gynn, to the northern boundary of the borough; and along Cocker street to Dickson-road; and from Cocker-street northwards in front of Carlton-terrace and along Queen's drive to the Gynn and that the town clerk be instructed to take all proceedings requisite in the matter. The committee desired to place on record their appreciation of the services to the electric lighting department rendered by Mr. Robert Hammond, consulting electrical engineer,

Digitized by Google

during his association with the Corporation, and their satisfaction with the system of electric lighting adopted by them on his advice.

Ipswich.—The County of London and Brush Provincial Electric Lighting Company, Limited, have written to the Council stating their intention to proceed with their notice of application for a provisional order for electric lighting in Ipswich, and Mr. E A Paris, the representative of the company, has attended a meeting of the Paving and Lighting Committee, and stated that when he attended before the committee felt that the matter was beyond the province of the committee, and that the Electric Lighting Committee was either defunct or had completed the work for which it was appointed. The company afterwards made application to the Council, but from some misadventure it did not reach the town clerk till too late to be placed upon the agenda paper of the Council meeting then to be held. Since then the company had been unable to get any further, and they had waited to hear the views of the Corporation. They would ask whether the Corporation meant to oppose pure and simple, or whether some common basis of negotiation could be found by which they could come to an agreement to purchase the undertaking, either after a term of years or immediately after the installation was put down. What the company desired was some means of getting the matter further discussed. If the committee could see their way to further the company's views and bring the matter before the Council or a special committee to discuss these points, the company would be very pleased to take any step the committee might suggest. It was necessary for the company to publish advertisements during November of the streets in which they intended to lay their wires, and before they went further they would like some expresssion of opinion from the Council. The Town Clerk said it was unfortunate that the company were always a few days too late. Last summer the company were advised when the Council meeting would be held, and then made their proposition only a day or two before that date, altogether too late to get the notice on the agenda, and they were in just the same position now, though it was perfectly well known that all over England the annual meeting of every town council was held on November 9 The matter could not now be discussed this month. Mr. Pratt said, notwithstanding the incandescent lamps, many would like the electric light, and suggested the possibility of holding a special meeting of the Council. Mr Paris enquired when the next Council meeting would be. The Town Clerk said the second Wednesday in December. The company would have to issue their advertisement before then Mr. Paris agreed, and promised to supply to the Council full details as to the area of compulsory supply. It will be remembered that the electric light was at one time supplied in Ipswich by a company. The enterprise, however, from various causes did not succeed, and there are at present in the town establishments wired and fitted for lighting and unable to obtain any current.

Manchester.—At the last ordinary meeting of the Board of Directors of the Chamber of Commerce the question of telegraph charges to the Far East was discussed. In view of the international telegraph conference to be held next year at Budapest, the India, China, and Colonial Committee had had under consideration the high charges at present levied by the telegraph companies for messages between Great Britain and India and the Far East. Following up previous representations from this Chamber, it had been agreed that a letter should be addressed to the Government asking that its influence should be used in favour of effecting a reduction of the present rates. The Board approved this course The Board had also before it a letter from Lloyd's urging the expediency of restoring telegraphic communication with the Fastnet Rock, so that passing vessels might be reported, and information of casualties conveyed to Lloyd's and the various shipping firms interested in the mail steamers which run from America. Proper arrangements have been made with the Commissioners of Irish Lights as to the service, and the rock had been connected with the mainland by Government. It appeared, however, that the Board of Trade, the owner of the cable, did not seem inclined to allow Lloyd's messages to pass, and the efforts of the Chamber were requested to induce the Board of Trade to accord to Lloyd's the necessary facilities. The Board cordially agreed with this application, and decided to support it by a communication to the President of the Board of Trade. The City Council of Manchester passed on Wednesday a resolution authorising the promotion of a local Bill in Parliament next session for the carrying out of various objects. Afterwards a meeting of property-owners and ratepayers was held, at which the action of the Council was submitted for approval or otherwise. The Lord Mayor presided. Strong opposition was forthcoming to a proposal for a clause in the Bill to empower the Corporation to work and demand and take tolls upon the tramways in the city, and to use electric or other mechanical power as a mode of traction thereon. Alderman Sir A. Marshall said the committee which had been appointed to consider the desirableness or otherwise of the Corporation taking over the Carriage and Tramways Company's concern had not yet reported. The Bill did not seek to commit them in any way, but simply empowered them to treat, if it should be decided to approach the company. Mr. Earnshaw one of the leaders of the opposition, said the members of the City Council were already complaining of being overworked in the city's interest. By taking over the tramways they would have to create an entirely new department, and would saddle the ratepayers with the wages of a new set of officials. Other speakers complained that the subject was being thrust upon the ratepayers, and held that as the Corporation went to Parliament every year for a new Act, they could easily wait until nearer the time when the tramway company's leases would fall in. The meeting refused to sanction the proposed clause.

Electric Tramways in London.—Mr. J. Clifton Robinson, A.I C.E, who is widely known on both sides of the Atlantic in connection with matters of tramway management and engineering, writes to the *Pall Mall Gazette*: "I would crave a little of your space to show, in the first place, what has stood in the way of this advance in tramway traction, and thereafter to illustrate its benefits by reference to tramway extensions and conversions in which I have been actively engaged for the past two or three years. The result of extended observation and practical knowledge is my conviction that up to the present time no method of traction has been introduced that is so safe, so economical, and of such universal applicability as the overhead electric trolley system. As regards the obstacle in the way of introducing electric traction into London, the most instructive way I can show this is to give a plain narrative of the facts. In the autumn of 1894 the London United Tramways, Limited, of which I am the managing director, turned attention to the powers granted to their predecessors, the West Metropolitan Tramways Company, under Acts of Parliament passed in 1889 and 1891. These included the reconstruction as double line of the tramway in the Uxbridge-road, between Shepherd's Bush-green and Acton, and my company sought to take advantage of the opportunity when rebuilding this line to introduce the most approved form of electric traction as an object-lesson within the metropolitan area. From various considerations, such as the width and suitability of the roadway, the character of the district, and the opportunity afforded of combining the electric lighting of the road with the working of the new tramway, the company regarded the circumstances as especially favourable, and proceeded to obtain the necessary consents of the local authorities. The assent of the Hammersmith Vestry was unanimously granted on November 14 of last year, after members of the Vestry had visited Havre, as one of the most recent and most easily accessible examples of the adoption of the overhead wire system within a busy city. The Vestry also appointed a deputation of their Works and Electrical Committee to attend the London County Council in support of the company's application. Statements showing fully what was proposed and indicating the extraordinary progress of electric traction in America, on the Continent, and in this country, as well as illustrations of the general appearance of the line then under construction at Bristol, were submitted by me. The matter was remitted to a committee whose report was strongly against the consent being granted, the objections raised by this committee being apparently of an entirely sentimental character. With such a report presented to it it is perhaps hardly surprising that the London County Council refused its consent, though it is a thing to marvel at that the refusal, which was carried by a large majority, was really the act of the so-called 'Progressive' members of the Council, and was based upon such fantastic assertions as that the plan would 'becloud the sky with a metallic cobweb' or that in America surrounding property had deteriorated where electric overhead traction had been introduced. If these objections were well grounded, how are we to reconcile the construction or conversion of 10 000 miles of electric tramways on this system in America within the last eight years? The refusal was given on January 29 last. As, however, illustrations of practical success are of more value than myriads of unfounded objections, I should like to show briefly what has just been done in Bristol, on the basis of my report to the directors, and what is in progress in Dublin, Leeds, Birmingham, Glasgow, and other large cities. The electrical overhead line at Bristol, which was inaugurated on October 14, forms part of the system of the Bristol Tramways and Carriage Company, Limited, founded in 1875, and now comprising a system of 18 miles of tramways. The electric section, four miles in length, consists of two miles of line reconstructed leading from the heart of the city to St. George, and two miles of new line opening up the manufacturing district of Kingswood, the route presenting every possible difficulty, including narrow and congested thoroughfares. Gradients up to 1 in 15 are encountered, and these are surmounted by the electric motor car, trailing an ordinary car, both fully loaded, and maintaining a uniform speed of eight miles an hour without apparent effort or difficulty. The 'trolley' wire is supported at a height of 21ft. from the ground, in some parts by centre standards carrying also the electric light, and in some cases also the gas lamps, and sometimes upon standards at the kerb with an arm or bracket supporting the two wires. The standards are placed at an average distance of 120ft. The best testimony to the success of the installation, apart from the many signs of public appreciation since the opening of the lines, is afforded by the opinions expressed at the inaugural ceremony by Prof. Silvanus Thompson, F.R S, whom everybody will recognise as one of the most competent electricians of his time. On behalf of the gas and water interests of Bristol, Prof Thompson watched the process of construction both openly and by covert visits, and his testimony is that, while the efficiency of the mode of traction is unquestionable, the requirements of the Board of Trade for the safety of the public and for the prevention of electrolysis in the street pipes had been most fully carried out. The Bristol local authorities and the Bristol people fully endorse his views as to the outward appearance and practical working of the new system. A beautifully illustrated pamphlet describing the Bristol installation has been prepared, and to those who cannot visit the city it will show conclusively how futile are the so-called æsthetic objections to the overhead trolley system. Some further practical facts may be stated. On one of the Bristol horse lines, now carrying 2¾ millions of passengers yearly, the loss from lack of speed over this difficult route is calculated to amount to a 'sinful waste of one year in a week.' The

Digitized by Google

electric car can double the daily mileage, and thus give twofold the accommodation to the public. The car is fitted with electric brakes by which, independently of the line circuit, the motor-man can stop the car within its own length, even on the steepest descent. The cars are larger and more commodious, they are self-lighted, so to speak, with the electric light at night, and already a quarter of a million of passengers have been carried in safety, and without hitch or delay, despite the disadvantages of opening a new electric system at this season of the year. Outside the power-house, the whole staff of men and boys has been drawn from the ordinary horse-car service, and with a very short training become efficient in the management of the motors."

PROVISIONAL PATENTS, 1895.

NOVEMBER 4.

20790. **Improvements relating to filaments for electric incandescent lamps.** Frank Eustace Wilkins Bowen, 55, Parliament-street, London.

20801. **An improved means for electrically lighting gas jets from a distance.** Oscar von Morstein, 89, Chancery-lane, London. (Complete specification.)

20815. **Improvements in coin-released machines which are electrically driven** Edward Thomas Middlemiss 23, Coleman-street, London.

20821. **An improved reflector for electric arc lamps.** Vincent Fabris, 64, Mark-lane, London.

20824. **Improvements in or relating to electric batteries.** Walter Grimes, 323, High Holborn, London.

20828. **Improvements in or relating to primary electric batteries.** Walter Rowbotham, 45, Southampton-buildings, Chancery-lane, London.

20835. **Improvements in or relating to insulating conduits or tubing and connecting boxes for containing electrical conductors.** Alfred James Perton Whitaker and Frederick Gwilym Treharne, 45, Southampton-buildings, Chancery-lane, London.

NOVEMBER 5.

20843. **Improvements in electric batteries.** Charles Percy Shrewsbury, Frank Laurence Marshall, and John Laskey Dobell 57, Chancery-lane, London.

20883. **Improvements in electric systems.** Philip Middleton Justice, 55, Chancery-lane, London (William H. Nixon, (United States.) (Complete specification.)

20904. **Improvements in controlling electric motors by the three-wire system** James Devonshire, 70, Chancery-lane, London. (William B. Potter, United States.) (Complete specification.)

20905. **Improvements in electrically-driven machinery.** Edward Neville Bray, Heathbourne, Wandsworth Common, London.

20917. **An improved form of electric candle fitting.** Edward Bulstrode, 106, Crofton-road, Peckham, London.

20923. **Improvements in electrical annunciators.** William Phillips Thompson, 6, Lord-street, Liverpool. (Henry Buckner Higgins, United States.) (Complete specification.)

20924. **Improvements in electrical annunciators.** William Phillips Thompson, 6, Lord street, Liverpool. (Henry Buckner Higgins, United States) (Complete specification.)

20925. **Improvements in batteries or compound bells applicable for pocket electric lamps and for other purposes.** Edward Burnet, 6, Lord-street, Liverpool.

20926. **Improvements in block systems for electric railways.** Reginald Belfield 31, High Holborn, London.

20928. **Improved means and appliances for regulating the feed of carbons in electric arc lamps.** James Jeffryes and John Lea, 166, Fleet-street, London.

20940. **Improvements in printing telegraphs.** James Yate Johnson, 47, Lincoln's-inn-fields London. (Jonathan Edwards Woodbridge, United States) (Complete specification.)

NOVEMBER 6.

20986. **Improvements in collecting brushes for dynamo-electrical machines, electrical motors, and other electrical machines and apparatus** John Lenderyon, jun., and John Williams, jun., 7, Staple-inn, London.

NOVEMBER 7.

21045. **Controlling electrical switches.** James Browett and Herbert Arthur Henderson, 4, Corporation-street, Manchester.

21050. **Improvement on the preparation of hydrosulphite of sodium by the electric current.** Leon Marchlewski and Michael Hertz, 25, Wellington-street, Higher Broughton, Manchester.

21090. **Improvements in or relating to welding or joining together metals by electricity.** Herbert Alfred Bessemer, 93, Ritherdon-road, Upper Tooting, London.

NOVEMBER 8.

21137. **Electrical tramway and railway conductors.** George Hinde Nisbett, 8, Quality-court, Chancery-lane, London.

21146. **Improvements in the construction of tubes or conduits for electrical conductors.** Frederick Bathurst and Gustav Binswanger, 88, Queen Victoria-street, London.

21153 **Improvements in or in connection with arc lamps.** Frank Michael Lewis, 30, Park-row, Leeds.

NOVEMBER 9.

21283. **Improvements in the electro-depositing of metals.** Alexander Stanley Elmore, 28, Southampton-buildings, Chancery-lane, London. (John Oliver Surtees Elmore, India)

21297 **Improvements in automatic electric arc lamps and automatic cut-outs.** George Henry Church, 2, Lancaster-place, Strand, London.

SPECIFICATIONS PUBLISHED.

NOTES.

Electro-Harmonic Society.—Electro-musicians are reminded that it is ladies' night on Saturday, November 30, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock.

"Autocars" in Scotland.—A Glasgow engineer, Mr. George Johnston, the inventor of a mechanical tramcar, is now running an "autocar" in the streets of that city. It is stated that this is the first horseless carriage to be seen on the other side of the Border. The motive power of the conveyance is not stated.

The Cleveland Accident on Saturday last was a terrible affair, but the fact that electricity was the motive power of the unfortunate car of course had nothing to do with the disaster. It seems incredible that even carelessness should be allowed to be responsible for a driver or a conductor of a car imagining that a drawbridge was in place when it was not, and plunging so many people into a watery grave.

Telephones in Collieries.—At the last meeting of the Midland Institute of Mining, Civil, and Mechanical Engineers at Sheffield, Mr. A. R. Bennett read a paper on "Telephonic Communication in and about Coal-mines." While not disparaging any of the systems now in use, he suggested, to avoid the use of an exchange in a colliery, that several insulated wires might be braided together into one cable, that each station might have the means of communicating with any other station independently of an exchange.

The "Booster" System.—In case there should be an electrical engineer who is not by this time thoroughly posted on the subject, it may not be amiss to state that the "Booster" system consists in the introduction into a feeder, and in series therewith, of an additional E.M.F. to compensate for the loss of voltage on the said feeder. Usually this is accomplished by a generator whose voltage is made to vary with and adapt itself automatically to the varying loss on the feeder by causing its fields to be excited wholly or partially by the varying current on the feeder.

Phosphorescence after the Passage of an Electric Discharge.—Some recent experiments have been made by a French scientist, M. Seguy, on the phosphorescence of rarefied nitrogen after the passage of an electric discharge. He found that nitrogen in the presence of a metallic bichloride (stannic chloride, for example), phosphoresces like oxygen after an electric discharge. The light emitted during the discharge is pink, and the phosphorescence milky white, of greatest intensity immediately after the break of the current, and gradually diminishing until it disappears at the end of from 10 to 80 seconds.

Light Railways in Germany.—As evincing the interest which has for a comparatively long period been taken in Germany in the construction of secondary railways, it may be noted that since the beginning of last year the Minister of Public Works in Prussia has issued a monthly publication on light railways—the *Zeitschrift für Kleinbahnen*. The October number contains a map of all the existing and proposed light railways in Belgium, and also publications of English, French, and German works issued from time to time since the September number was published. It is well illustrated, and is published by Herr Julius Springer in Berlin.

Hawking Incandescent Lamps.—According to the *Financial Post*, the London pedlars have taken to hawking electric incandescent lamps. This paper says, "Although the gas interests persist in asserting that the electric light is a luxury, and that there is no chance of its becoming popularised in the wide sense, it is a sign of the times, as one learns from a police-court charge, that a street hawker—and street hawkers are a shrewd class—should consider it worth his while to buy electric incandescent lamps and display them on a barrow for sale in the thoroughfares." Perhaps (our contemporary the *Gas World* suggests) the hawker was selling the bulbs as a new kind of air balloon.

Edison's Retaining Fees.—A month ago Mr. Edison was notified by Mr. C. A. Coffin, president of the General Electric Company, that his retainer fee of 400dol. a week would be discontinued at once, but that if he (Edison) were in need of money the same sum would be advanced to him every week and charged to his account. Thomas Alva did not accept the situation cheerfully. He at once called on Messrs. J. P. Morgan and Co. and "expressed himself with some emphasis." It was finally decided, it is stated, to place him upon the pay roll of the Edison Illuminating Company of New York for an equivalent amount "for services rendered in years past."

City and Guilds of London Institute.—We gather from the report for the session 1894-95 of the City and Guilds Technical College, Finsbury, E.C., that during the session 210 day students have been in attendance, of whom 95 were in the electrical department, 59 in the mechanical department, and 56 in the chemical department; while of these 210 day students 159 reside in London and suburbs, 49 come from outside a radius of 10 miles from London, one from Canada, and one from Holland. The past students of the two engineering departments—electrical and mechanical—show a good record of subsequent successes. With regard to the evening classes at the college, 1,119 tickets have been sold to 926 individual students, compared with 1,091 tickets sold in the preceding session to 922 students.

Telegraphing in Tunnels.—Mr. R. S. Culley, of Weston-super-Mare, remarks that it is interesting to see how supposed electrical impossibilities recur to the imagination of the public. A statement has been recirculated that it was found impracticable to send a telegraphic message through the Hoosac Tunnel, 4½ miles, even by means of a well-insulated wire, apparently because of iron ore present in the rock. He writes: "Now about 45 years since, the Sheffield and other local papers attributed the difficulty of signalling through the Woodhead Tunnel—Sheffield and Manchester—to a similar cause, the supposed existence of iron ore, whereas, of course, the only reason was the bad insulation of the wires. I recollect the case well, as I had to spend several Saturday nights and Sundays in the tunnel—a little over three miles long—to put matters right. In that case, as in the Hoosac instance, the wires were eventually carried overland on poles, simply because this was cheaper than properly-insulated wires through the tunnel."

A Safety Appliance for Live Wires.—Mr. A. E. Hutchins, of Detroit, has patented a method of cutting out live wires carrying heavy currents which seems to possess several meritorious features, and which, in view of the Board of Trade discussion this week, is vested with opportune interest. A ground wire is attached to the pole supporting the wire, and this ground wire is connected with a metallic plate or pipe buried in the earth. The upper end of the wire attached to the pole is connected with a specially-made insulated metallic bracket in the form of a crotch or fork. Just above this bracket the line wire is bared for a few inches. If an accident should happen, causing a break in the line wire, it would fall to the ground, the bare place would come in contact with the crotch in the bracket, and the heavy current would be diverted through the wire on the pole to earth. Mr.

Digitized by Google

Hutchins states that he has handled with perfect safety a line wire carrying a current of 3,000 volts when the pole was equipped as described.

The Electric Athletic Association.—The annual conversazione and distribution of prizes in connection with the Electric Athletic Association took place last Friday evening at the Holborn Town Hall. The Duke of Norfolk, Postmaster-General, who was received by a guard of honour of the Post Office Rifles, distributed the prizes and was supported upon the platform by the following officials of the Post Office and Telegraph Department: Mr. Spencer Walpole, Mr. H. C. Fischer, Mr. E. May, Mr. J. Eames, Mr. J. Hookey, Mr. J. Hill, Mr. C. T. Fleetwood, Mr. H. Preece, Mr. J. C. Lamb, and Mr. J. R. Langton. At the conclusion of the distribution, Mr. Spencer Walpole proposed a vote of thanks to the Duke of Norfolk, and remarked that the presence of his Grace that night was an assurance of his sympathy with the great staff of the General Post Office.

An Automatic Mercurial Air-Pump.—A mercury air-pump, somewhat akin in principle to Geissler's, and which may be called a reservoir pump, is described by Herr F. Neesen in *Wied. Ann.* It is worked by an auxiliary water-pump, the mercury being raised and lowered in the reservoir by the automatic motion of two valves, which allow the mercury in the cistern to be exposed to the atmospheric pressure or freed from it by the action of the auxiliary pump. The peculiarity of the automatic valve motion is that the valves are moved by a system of floats, of which one part varies its weight by admission and recess of mercury, so that there is the necessary difference of level in the cistern between the phases of valve opening and closing, corresponding to whether the mercury is rising or falling. The adjustment for preventing too rapid rise of mercury as the pressure falls below 1mm. is made by withdrawing a little mercury from the cistern into a side vessel. The author describes an arrangement with a tap instead of valves, the difference of phase in action being effected by an automatic variation of the leverage acting on the tap.

Prof. S. P. Thompson at Toynbee Hall.—Prof. Silvanus P. Thompson delivered the Saturday popular lecture at Toynbee Hall, East London, last week, choosing for his subject "The Magnetic Effects of an Electric Current." An electric current, he said, could produce magnetic effects, and electricity applied to a coil of wire made a magnet, but what was the relation between magnetism and electricity was a mystery which had yet to be solved. We wonder if Prof. Thompson has met the author of a work on "Magnetism: Its Potency and Action, with Suggestions for a New Cosmography and a New Celestial Geography," who gives the following definition of magnetism: "Magnetism is the connecting link between mind and matter, or rather the medium by and through which the Divine energy is imparted to all matter, and the primary exhibition of this energy is an exercise of God's will. The Deity is the omnipotent magnet. Electricity is condensed magnetism, and electricity, light, heat, gravity, sound, capillary attraction, repulsion, attraction, disruption, and explosion are modifications of magnetism, and are influenced by it."

Electrical Editors and Matrimony.—"Wetzler—Gerson.—At Delmonico's, Fifth-avenue, on October 30, Mr. Joseph Wetzler, editor and vice-president of the American *Electrical Engineer*, was married to Pauline, daughter of Mr. Jacob Gerson, of New York." Mr. and Mrs. Wetzler will please accept our congratulations. The journal *Electricity*, which, like Mr. Barnes, is of New York, remarks reflectively upon the happy circumstance: "The list of electrical newspaper men who have shown their wisdom and stability during the last year or two includes Messrs. Kreidler, Keily, F. L. Perry, Nelson W. Perry, Wetzler, and Montgomery. The only hesitant remaining, so far as we know, is Mr. W. D. Weaver, of the *Electrical World*. We trust Mr. Weaver may soon be brought to a realising sense of his unfortunate position and find a wife. Perhaps not the only, but certainly the biggest, cranks in the world are old bachelors and old maids—and the latter are not to be blamed, because they would not be so if every man did his duty. The community now waits for Mr. William Delinquent Weaver." We are puzzled to account for this apparent matrimonial reluctance on the part of American electrical journalists, unless it be that they imagine that there is some truth in the saw which says that while those whom the gods love die young, those whom the imps favour marry young.

New Railway and Tramway Permanent-Way Scheme.—Mr. W. H. M'Neight, of Dublin, has given demonstrations of "some inventions which are the result of 14 years' thought and labour, and which, if brought into practical use, will probably cause a remarkable change in the methods employed of laying down the permanent ways of railway and tramway systems. Expense is saved by dispensing with all the nuts and half the bolts at present used, but, what is more important, the tendency of the rails to get out of the straight is altogether avoided." Mr. M'Neight thus describes his methods as relating to railways: "Two powerful bolts with flanges on one end pass through the extremities of the connected rails and plates. At the other end of each bolt is a wedge-shaped mortice through which passes a wedge. The narrow ends of the two wedges face each other. They are connected by a bar with screw threads running in the ordinary direction at one end and in the opposite direction at the other end. When the screw bar is rotated it draws the two wedges together, and thus the plates can be tightened better than at present, while nothing but a reverse motion of the screw can by a hair's breadth alter the position." The plan for dealing with the permanent ways of tramcars is claimed to be even more simple and effective. "The chair is so constructed that the wooden wedge driven through it and the rail cannot leave its position unless taken out by a hammer, nor is it affected by changes of temperature." Mr. M'Neight's plan of laying tramway rails is one of dovetailing. When the transverse rails are put in their place, the rails are at one and the same time connected and gauged, and so kept in their position until the sets are put in. The usual allowances are made for contraction or expansion.

Cable Schemes.—At the private interview at the Colonial Office on Tuesday with the Agents-General for the Australasian and other colonies for the purpose of discussing the projected Pacific cable which it is proposed shall pass entirely through British territory, Mr. Chamberlain is stated to have observed that such a meeting was, in a sense, a meeting of the council of the Empire, brought together for the purpose of common interest, and that the presence of the representatives of the Cape and Natal, who were not concerned in the project in its present form, was an evidence of solidity and sympathy. He expressed his opinion that the project showed a very fair prospect of remuneration on the capital required, and his willingness to join in the formation of a joint commission which should report upon the subject. He also suggested that the commission should be formed consisting of representatives of Great Britain, two from Australasia, and two from Canada. After some discussion, it was arranged that the Colonial representatives should be named by the Colonial Office and appointed by the

Digitized by Google

Imperial Government, and that the commission should consider and report on the whole subject in all its aspects; and it was understood that the Agents-General and the High Commissioner for Canada would move their respective Governments to appoint representatives. It is stated that the Canadian Government is negotiating for the extension of the telegraphic service to Belle Isle, *vid* Bonne Bay, Newfoundland. This line would be of great benefit to shipping interests, as it would enable vessels from England to be reported the fourth day out.

Electricity on the Brooklyn Bridge.—We have already announced that the officials of the Brooklyn Bridge have requested the manufacturers of electric railway apparatus to submit bids for an electric system for switching the cable trains at the terminals. The specifications call for the equipment of each train with electric motors of sufficient power to move the train from the point where it leaves the cable on the incoming track to the point where the cable is gripped on the outgoing track. The overhead system will probably be employed, as the conditions are such that aerial wires can be strung at a small cost. One car of each train will be equipped with motors, and controllers will be located on the front and rear cars, so that the train may be operated from either end. During the trial of the electric system the current for operating the motors will be taken from the trolley wires of the Brooklyn City Railway. The switching at the terminus is at present done by steam locomotives. During the busy portions of the day about 75 trains an hour are operated, and considerable time is lost in making connections between the trains and switching engines. The adoption of the electric system will relieve the passengers of the disagreeable noise and smoke of the steam locomotive, and, it is believed, will greatly facilitate the handling of trains. The work will be pushed rapidly as soon as the contract is awarded. The construction of the new terminal stations is being prosecuted as fast as possible, and when completed, and the electric switching system is in operation, the inconvenience to which passengers are at present subjected will, it is thought, to a very great extent disappear.

Telegraphy in Western Australia.—There is great grumbling in Coolgardie just now on account of the alleged inadequacy of the telegraphic arrangements. It seems strange that a go-ahead country like "Westralia," whose population is at present growing by leaps and bounds, should apparently neglect to keep pace with the times on so important a question as that of providing telegraphic facilities. At any rate, an enthusiastic public meeting has been held in the Theatre Royal at Coolgardie for the purpose of considering what steps should be taken to improve the post and telegraph arrangements for the town and district. The Mayor presided, and the platform was occupied by the leading citizens of Coolgardie and Kalgoorlie, those from the latter place coming in specially to take part in the meeting. Mr. Thompson, chairman of the Chamber of Mines, moved that the meeting "strongly condemns the inactivity and apathy of the Government in not providing and maintaining a telegraphic service more nearly suited to the present and rapidly-increasing requirements of the field." Coolgardie, he said, would soon be second in importance to no town in the colony, and all the other portions of the district were also growing with great rapidity. The goldfields were united in their demands, and the Government was very foolish in attempting to resist them. Mr. Whittenoon seemed willing to do what he could, but Mr. Sholl, the Postmaster-General, was a stumbling-block, and it would be a good thing for the country if Mr. Sholl were persuaded to retire on full pay. This bold motion was carried unanimously. Mr. Howard Taylor next moved that, in the opinion of the meeting, it was absolutely necessary that the telegraph line to Perth should be duplicated at once, and a double line to Esperance be completed as early as possible. If the reasonable requests of the goldfields were not granted, he expected to see a large number of residents of Coolgardie about Christmas time hold the biggest meeting in Perth that the colony had ever seen, and beard the Forrests in their den. This resolution was also adopted. The Government of the colony must look to it that it does not belie the watchword of the island continent—"Advance, Australia!"

The Denayrouse Gas-Electric Lamp.—Attention is again being attracted to the scientific toy known as the Denayrouse lamp. It may be remembered that at the last annual meeting of the French Gas Institute M. Mallet said that he was happy in bringing under the notice of the society a "wonderful invention" of his friend M. Denayrouse, to which reference had been made a short time ago by Prof. Vivian Lewes at the Gas Institute in Edinburgh. M. Denayrouse had been struck with the idea of "blowing" the Welsbach burner, and this he did in a peculiar way. He mixed the air with the gas by the aid of an "almost insignificant" current of electricity, and secured absolutely unexpected results. In his lamp there was a metal receptacle, a small electrical motor, and an incandescent mantle. As they would see from the lamp shown them, the light was very intense, of a power of 35 or 40 carcels, and the lamp had a consumption of seven litres per carcel. The No. 2 lamp had a power of 80 carcels and a consumption of two litres per carcel. As they were now able to judge of the intensity of the light, he would explain the method of blowing. Inside the spherical lamp were two small accumulators, a tiny dynamo, and a fan. The energy developed by the motor was 1·3 volt and $\frac{1}{10}$th ampere. This set the fan in rapid motion, causing the air to ascend through the gas mantle like a blow-pipe. People might be inclined to say that the lamp was no doubt interesting, but somewhat complicated. There was indeed no inconvenience whatever, for with the almost general employment of electricity in their homes, the lamp would be reduced to the greatest simplicity. It also possessed another advantage, in that the lamp could be lighted automatically. M. Mallet, continuing, said that he thought in time the lamp would be able to compete with the arc lamp, not only in price, but also in intensity, for it was rare to see an arc lamp of 80 carcels. He thought that the arc lamp would have to "descend from its pedestal." The inventor of the lamp, M. Denayrouse, himself, however, is very wisely not so sanguine as his prophets. He certainly says that they do a great deal with an infinitely small quantity of electricity and a lot of gas, and they do it better than with electricity alone, and that instead of gas and electricity being enemies they have made them sisters, but as to the practical working of the lamp he will say nothing.

"Roundabout Notes in Electrical Europe."—Mr. E. J. Wessels brings to a conclusion his series of articles with this title in the New York *Electrical Engineer*. He visited 32 European cities in 54 days, so that his work was essentially hurried. He winds up with a generalisation which was doubtless exclusively intended for American electrical engineers, but which may prove interesting, and possibly wrinkle-giving, to electricians on this side. It is not, of course, necessary to agree with all his statements. He says: "It was gratifying to notice that there were very few things in use on electric roads abroad which can be employed advantageously here. This may seem like undue praise of our American manufacturers, but I believe

Digitized by Google

it to be true, and for corroboration need only mention the fact that the eyes of Europeans are constantly turned towards America, and that they watch developments here with eager interest. Some of them have their 'pickets' in our shops and on our roads, and thus are kept advised on our practice. . . . Several prominent officials informed me they took these [American] papers home, so they would not miss any of the contents. They regretted that business pressure prevented them from reading them in their offices. Those who couldn't read English had the principal articles translated. In Europe, representative men award the palm for progressiveness in the art to us here. These gentlemen are ready, therefore, to adopt anything we have which proves practicable for their use. There are difficulties in the way of building up foreign trade, but they are not insurmountable. It may be stated that correspondence should be conducted exclusively in the language of the country with which business is desired. In numerous places in Germany a letter written in English would not receive attention, while if it were written in German it might lead to business. To develop trade, it is essential that American houses should 'keep everlastingly at it.' They should send their literature to the various roads and open correspondence, calling attention to anything new. If the article be of real merit and adaptability, it is not likely to be long before a trial order will follow. That trial order will lead to large business. In view of the heavy duty and freight on many parts of equipment, it is desirable that, as far as possible, apparatus should be shipped 'knocked down' and in sections, and sometimes if 'unpainted' there will be a decided reduction in tariff. It will be a wise plan to secure good resident agents who will take pains to keep prospective buyers posted. Their efforts should be supplemented by forwarding literature from America. Apparatus intended for shipment abroad should certainly be patented. If patented, there is some chance of protection, but if unpatented, the sending of a trial order will only open the door still wider for infringement."

Electric Fire Hazard.—Mr. Ludovic MacLellan Mann writes upon the subject of fire risks incidental to the lighting of paper-mills. With regard to the use of incandescent electric lamps, he remarks that the top surface of the bulb in the dry department of the mill is apt to become thickly coated with fluff and dust, and that such a deposit upon the heated surface of the glass is dangerous and should be prevented from forming by placing the lamp in an outer glass globe arranged to exclude dust; and as to arc lamps, in order to decrease the risk of the emission of particles of incandescent carbon and the dropping of melted copper, the lamps should be enclosed at the base. This means of safety ought, Mr. Mann says, to be carried into execution in the wet as well as in the dry portions of paper-mills. Where the objectionable practice prevails of dispensing with globes for arc lights (as happens occasionally where ceilings are low or when it is found shadows caused by defects in the glass of the globes hinder the scrutiny of pulp), the lights should be provided with carbon-catching saucers or trays of large size and considerable depth. Unless where wet processes are carried on, naked arcs should be prohibited. As particles of carbon have, he continues, been seen to pass out even through the top openings of arc lamps, the complete enclosure of the lamps is desirable where loose sheets of spoiled paper, unboiled esparto, straw, heaps of rag fluff, and any other light dry materials are lying about, and where cutting and dusting are performed. A reasonable suggestion is that the aperture at the top of the globe of every arc lamp in the dry-process rooms be fitted with some kind of wire gauze of simple form—such as a piece of used-up paper-machine wire—always easily obtainable. Lighting-up might be made a less frequent cause of fire in gas-lighted mills which are dusty and contain inflammable stocks if that handy contrivance the electric spark-producer were oftener used. This cause of disaster is of course not a possible one in mills lighted entirely by electricity, and herein Mr. Mann sees a point in favour of the electric illumination of paper-mills. The question of the comparative profitableness in the long run of each illuminant really hinges, he thinks, upon the degree of soundness and appropriateness with which electric light installations are put in. It thus behoves the electrical engineer for his own sake to turn out only good and suitable work for his friend the paper-maker. Wiring and fittings in nearly every style are liable to injury by the incessant vibration which goes on in a paper-mill. A premature wearing away and loosening of parts together with corrosion and damp cause leakage of current and occasion frequent repairs. It is consequently found that some paper-mill owners are dissatisfied with their electric lighting installations. Mr. Mann therefore emphasises the necessity of good workmanship and good material. Chlorine gas may be styled the arch-enemy of electric light installations because of its pernicious effect, when moist, upon wood, metals, and other substances used for protecting wires. In the course of time it rots woodwork and corrodes all save some of the rarer metals. The pulp and bleach liquor tanks are the places to which chlorine gas is intended to be confined, but it cannot be prevented from escaping and diffusing itself throughout the atmosphere of the wet department and even in many instances of the dry-process rooms. Experience suggests the suitability for paper-mills of the concentric system of wiring with its lead-enveloped conductors. As it is found, however, that even lead, after an exposure of many years, will become damaged in a moist and chlorine-laden atmosphere, it might be well to run through gas-piping the lead-covered conductors used in the concentric system, and to employ junction-boxes of a low grade of cast iron. Moreover, rats, so numerous in most paper-works, would by this means be prevented from gnawing the lead of the conductors. It is a matter of the first importance to be able to resist the chlorine corrosion referred to. Varnishes may be discarded as unsatisfactory. Use might be made of the property possessed by lead chloride to form insoluble sulphate of lead in the presence of dilute sulphuric acid or solutions of soluble sulphates. Protection might therefore be secured were the lead sheathing in exposed situations wrapped in, say, asbestos cloth or felt well saturated with a solution of some soluble sulphate. The doctoring of the lengths between joints is, however, not so vital a matter as giving attention to the joints themselves. Water-tight, fire-proof junction-boxes are to be strongly recommended. One method of wiring suggested for paper-mills is to have the insulated conductors suspended from beam to beam and supported by rubber hooks or by porcelain insulators at each resting place. The objections to this system are that the wiring and supports are apt to become injured by the moving about of ladders when repairs are in progress and by the vibration of machinery. The most natural and convenient place for a dynamo is in or near the engine-house. This is also the safest position where, as is arranged in all well-appointed mills, the engine-house is outside the mill premises. In conclusion, Mr. Mann says that, given an installation put up soundly and after the styles indicated as trustworthy, and a competent engineer in charge of the machinery producing the light who is always ready to replace broken lamps and to do repairs of all kinds and to make frequent tests, the electric fire hazard may be reduced to a minimum.

THE QUALITIES OF MANGIN AND PARABOLIC MIRRORS.

We have received from M. Jean Rey the following letter in reply to that of Mr. Nerz in our issue of August 2 last. Though we propose to continue to deal with this subject, which is one of national importance from a military and naval point of view, we regret that we cannot afford space for any further correspondence:

"I trust your readers will pardon me for continuing the discussion on projector mirrors, but Mr. Nerz's letter in your issue of August 2 forces a reply. In the course of the only conversation which I have had the pleasure of having with Mr. Nerz, I well remember that he characterised the invention and production of the Mangin mirror as having been '*the* great step in electric searchlighting, which can be compared to the introduction of rifled guns for artillery purposes.' Such an expression from so great an expert is well worthy of note.

"With regard to the Toulon experiments, I am unable to quote from an unpublished report, but in a statement appended to the French Naval Budget for 1896 will be found the following: 'It is quite possible to make certain with regard to the defence of our ports and of their entrances by means of submarine mines and of searchlights. Comparative experiments recently carried out with the greatest impartiality between the searchlights employed in our ports and the parabolic projectors used by several foreign navies have proved the superiority of our own material.'

"I now propose, firstly, to show that parabolic glass mirrors are quite unsuited to military requirements; and, secondly, to examine the value of certain theories put forward in their favour. In my last letter I referred to the fact that 50 per cent. of the 90cm. × 42cm. Schuckert mirrors, in an important European coast fortress, had perished from concussion and overheating, but I have recently ascertained on good authority that in the fortresses of a mountainous country it has been found that Schuckert mirrors get fractured when in the neighbourhood of heavy guns. Nobody familiar with the manufacture of glass can be surprised at the frequent breakage of thin pieces of convex glass. It is the initial bending of the glass on a mould when hot which weakens it, and which subsequently brings about its fracture. My firm has had great experience with this very class of construction during the last 70 years. We not only made the first parabolic mirrors in 1856 for use in Foucault's telescope, but have also since made a great number of other thin glass reflectors, and we know from experiment that they will not stand the concussion of heavy guns.

"Turning now to the question of the degree of accuracy obtainable in the manufacture of parabolic mirrors, I must confess that I fail to understand Mr. Nerz's explanation of the 7mm. limit, which was the smallest which a Government was able to insert in their specification. I note that Mr. Nerz aims at providing different focal lengths for the separate zones of his mirrors, but I fail to see that any reasonable rule is followed in fixing these focal lengths. Quite recently I attended some curious and interesting experiments made with a 90cm. × 42cm. Schuckert mirror belonging to a foreign Government. The method employed was a strict one, and the focal lengths came out as follows:

Zone	90cm. to 80cm.	diameter	415·9mm.
„	80cm. to 70cm.	„	418·2mm.
„	70cm. to 60cm.	„	420·9mm.
„	60cm. to 50cm.	„	420·9mm.
„	50cm. to 40cm.	„	421·2mm.
„	40cm. to 30cm.	„	421·9mm.
„	30cm. to 20cm.	„	422·2mm.
„	20cm. to 10cm.	„	424·0mm.

"The maximum difference between these readings is 8·1mm. Such a mirror cannot be said to be paraboloidal; it is merely a pseudo-paraboloidal mirror.

"In various publications, Messrs. Schuckert and Co. have repeatedly argued that the parabolic mirror is superior to the Mangin mirror, as the former is constructed with a shorter focal length than the latter (*vide* an article by Max Braun in the *Neue Militarische Blatter* of Berlin, 1888, p. 370; the July number of the *Elektrotechnische Zeitschrift*, 1890, p. 372; also the *Zeitschrift des Vereines Deutscher Ingenieure*, No. 33, of August 13, 1892, p. 957). It is only recently that in the *Elektrotechnische Zeitschrift* of July 5, 1894, p. 367, Mr. Nerz sets aside the influence of the focal length upon the illumination of the objective. The terms he employs, however, are not properly defined, and the reader is led to confuse the luminous flux utilised, with the actual illumination of the objective. It does not follow in the least that an optical apparatus making use of a greater flux should produce a stronger illumination. Thus it is said by Mr. Nerz that a 60cm. × 25cm. Schuckert mirror receives a luminous flux twice as great as that received by a 60cm. × 42·5cm. Mangin mirror, but he omits to state *that the illumination of the objective remains the same in each case.* The focal length merely influences the compass of the beam, and it is not always desirable from a military point of view to increase the compass by shortening the focal length.

"Mr. Nerz's theory is exposed in the article in the *Zeitschrift des Vereines Deutscher Ingenieure* above quoted. To simplify the problem, he supposes the source of light to be spherical, and he seeks the flux received by the mirror. From this quantity he deduces a certain mean illumination by introducing the mean radius vector of the paraboloid, and he, nevertheless, then supposes that the value of this mean illumination is that of the sectional area of the beam at its issue from the reflector. With this hypothesis he calculates the illumination of the sectional area at any distance, and then compares it to the direct illumination of the same surface by the source without a reflector. He thus obtains an expression for the 'condensing power.' The formula, however, is not exact. In the first place, the hypothesis is not correct; and, in the second place, he confuses the *illumination* (or ratio of a flux to a surface) and the *intensity* (or ratio of an elementary flux to the solid angle it contains); thirdly, the supposition that the illumination of the sectional area of the beam is uniform, is in opposition both to theory and to practice. These three errors vitiate all the above arguments.

"Admitting, for the sake of argument, that the source is spherical, and that it produces a homogeneous flux, the illumination of the sectional area of the beam of diameter 'F,' at a distance 'e^1,' (I use Mr. Nerz's notation) can be immediately deduced. It is the quotient of the total flux received by the mirror, by the area of the circle, F—that is, it is:

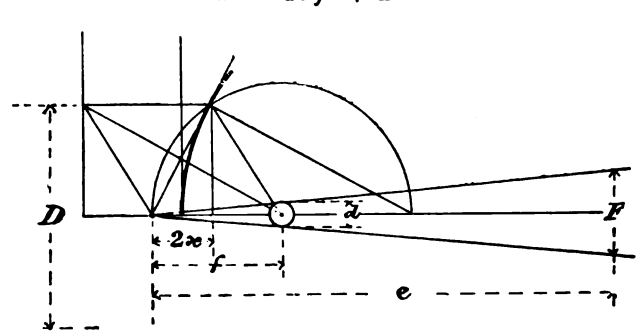
$$4\pi \mathrm{I} \times \frac{x}{f+x} \div \frac{\pi \mathrm{F}^2}{4} = \frac{16\,x\,\mathrm{I}}{\mathrm{F}^2(f+x)} = \frac{\mathrm{D}^2}{e^2 d^2} \times \frac{16 f^2}{16 f^2 + \mathrm{D}^2} \times \mathrm{I},$$

where f = focal length;
$2x$ = sub-tangent;
F = diameter of circle illuminated;
D = diameter of mirror;
d = diameter of crater;
e = distance of illuminated circle.

Note.— $$x = \frac{\mathrm{D}^2}{16 f} \text{ and } \mathrm{F} = \frac{e\,d}{f}.$$

"The ratio between this illumination and that the source of light would produce directly without the reflector—viz., I/e—gives the exact expression of the 'condensing power'—viz.:

$$\frac{\mathrm{D}^2}{d^2} \times \frac{16 f^2}{16 f^2 + \mathrm{D}^2}$$



I say, the exact expression, insomuch as the hypothesis is so itself. This expression includes the focal length, and

Digitized by Google

the illumination would be a function of it. The value found by Mr. Nerz, though not exact, is also a function of the focal length, because of the '$\cos^4 \frac{\delta}{4}$' which it contains.

"Unfortunately for all these calculations, however, the hypothesis is false; the light is not homogeneous, and the source is not spherical, and an expression for the '*condensing power*' which would depend upon the diameter of the crater is not supported by facts either for the Mangin and parabolic mirrors or for any other optical apparatus. It is now known that the only factors which enter into an expression for the luminous power of a reflector are the area of the reflector and the intrinsic brilliancy of the source. The intrinsic brilliancy of the crater of the voltaic arc is sensibly constant, and the reflector simply reproduces it at everyone of its points. The fundamental error of the theory of 'condensing power' comes from the supposition that the illumination of the beam is uniform. Such uniformity does not exist. All beams produced by optical instruments are composed of two zones—the first central, more or less extended, with constant illumination; the second around the former, with illumination decreasing from the centre to the edges. The *luminous power* is but the intensity measured in the central zone at unit distance from the projector.

"It is easy to see that the illumination of the beam cannot be uniform. Each part of the mirror produces a cone of reflected rays; the angles of these cones become less and less as we approach the edge of the mirror. The total beam is the result of the superposition of these different cones. This shows the difference between 'condensing power' and 'luminous power.' The luminous power is a physical quantity measurable in any given beam. The condensing power is a mean value of a fictitious nature, and is not applicable to any part of the beam. Colonel Mangin fully recognised these principles, but, curiously enough, Mr. Nerz brings into the value of the 'luminous power,' not only the diameter of the crater, but also a certain mean spherical luminosity, which has no true significance, as the arc does not produce a homogeneous flux. M. Blondel, in his 'Theorie des Projecteurs Electriques,' has treated the theory of brilliancy very clearly, and the consequences of his treatment are simple. The luminous power does not increase either when the focal length is diminished or when the current is increased, always provided that the reflector is aplanatic and that due regard is paid to the cone of shade thrown by the negative carbon, and which varies according to the position of the amp.

"Now, Mr. Nerz clings implicitly to these clear realities in his table of powers of the Schuckert searchlights given by him in the *Elektrotechnische Zeitschrift* for July 5, 1894, and though his table purports to be calculated by the help of the former hypothesis of a spherical mean, his figures, strange to say, justify the theory of brilliancy, and are in contradiction to his formulæ. Thus we see that the three parabolic mirrors of 90cm. diameter, with focal lengths of 31cm., 38cm., and 42cm., have the same 'power'—viz., 61,000,000 candles. Now, $\cos^4 \frac{\delta}{4}$ represents for these three types ·628, ·713, and ·765 respectively, and we should obtain for their luminous powers the values of 61,000,000, 66,000,000, and 73,000,000 candles respectively. This is taking as correct his values for 'd' and 'I_8.' It is clear, therefore, either that Mr. Nerz's formulæ are correct and his figures wrong, or that his formulæ are unsound and his figures based on more rigid principles. In either case, the results obtained in practice do not agree with the consequences of true theory.

"With regard to the question of absorption, Mr. Nerz estimates the efficiency of the parabolic mirror as 90 per cent. This ratio is too great when one takes into account the losses at the entry of the rays into the glass, at their issue from the glass, and the absorption of the silver itself, which, under most favourable circumstances, amounts to 10 per cent. In M. Blondel's treatise, 'On the Determination of the Mean Spherical Intensity of Sources of Light,' will be found a remarkably exact and simple method of measuring efficiency. Two descriptions of measurement only in each case are sufficient, and these I have made for a Mangin mirror of 90cm. diameter and of 45cm. focal length, with edges 70mm. thick, and for a parabolic mirror of 1m. diameter of 40cm. focal length and 7mm. thick. These two reflectors were both in identical conditions of perfect polish and silvering, and were illuminated by a 120-ampere horizontal lamp. The series of observations gave results which agreed well together. The Mangin mirror came out with an efficiency of 85·4 per cent., and the parabolic mirror came out with an efficiency of 85·3 per cent. This experiment entirely does away with the idea that the Mangin mirror suffers in efficiency from absorption in the extra thickness of glass at its edges.

"The weak point of my opponent's reasoning has always been to suppose that Mangin mirrors could not be made with short focal lengths, and that they could not be severely calculated. Whatever Colonel Mangin's ideas were in 1873, it is certain that his mirrors have been greatly improved since that date. With this optical combination all focal lengths can be obtained, and the conditions shown to be the best by theory can be realised. Mr. Nerz was not, I think, aware of this until a comparatively recent date, and he cannot now put forward the argument that the parabolic mirror is the only one capable of being constructed with a suitable and sufficiently short focal length. I may even say that the improvements which have been realised, and which render the present Mangin mirror the most perfect and appropriate optical apparatus for military purposes, have not yet reached their limit. As in astronomical and physical instruments, so it is with the Mangin mirror, that the combinations of spherical surfaces with glasses of suitable indices of refraction always give results which are superior to those obtained where attempts are made to produce surfaces of non-uniform curvature.

"Mr. Nerz is in error in stating that I am an enemy of the horizontal lamp. I have always maintained that the employment of such a lamp with long focus mirrors is to be rejected, but with reduced focal lengths the inclined lamp is inferior to the horizontal lamp. Of this I have been well aware since 1888, and there is nothing astonishing in the employment of the horizontal lamp with Schuckert projectors, as they are all of short focus.

"In conclusion, I may state that I am not yet prepared to be converted to the parabolic mirror, and that experience proves to me more and more the accuracy of foresight of the French officers and engineers who created the art of the projection of light."

THE THOMSON MULTIPLE-CIRCUIT ARC LIGHT DYNAMO.*

Prof. Elihu Thomson has recently devised an interesting form of multipolar dynamo directly connected for a series of arc light circuits, and in which the commutation and regulation of each of the separate circuits is as simple as in the ordinary types of arc lighting machines. A series of arc lights may be run with continuous current on each circuit if desired.

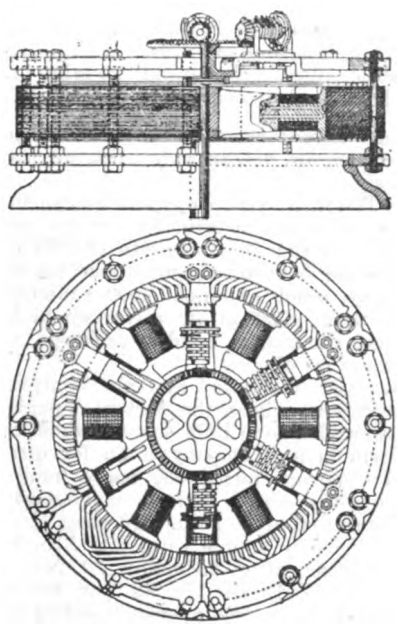
The machine is shown in plan and sectional elevation in the accompanying illustration. It consists of a revolving set of multipolar field magnets on a water-wheel or steam-engine shaft, the number of poles being chosen with respect to the speed and rate of cutting of the lines desired. The armature is stationary, and is provided with circuits non-overlapping, constituting groups of three coils or three-phase windings, from which three terminals are carried out. This winding is supported on a laminated structure, divided into sections, so that any section may be removed with its winding for repairs without disturbing the integrity of the rest of the structure, which may even be run with one or more sections removed.

In order to commute the currents, commutators are driven synchronously with the machine or at higher rates by direct gearing as shown. The machine shaft carries a large gear, which engages with small pinions on each of the

* From the *Electrical Engineer* (New York).

Digitized by Google

commutator shafts, the commutators being revolved at a speed relatively greater than that of the main machine in the proportion of half the number of poles in the main machine—that is, the commutator is virtually bipolar, or if the commutator has four poles its speed would be one-half as great. If the field poles of the main machine are 12 in number, as shown in the figure, the commutator would revolve six times as fast (if bipolar) as the machine. Each of the commutators carries three rings for connection by brushes to the stationary armature windings, and carries, also, a three-segment commutator with the ordinary arrangements of brushes, either controlled or not by a regulator.



The currents of the machine may be made by the armature reaction, resistances, etc., to be of the nature of those supplied by arc lighting machines, tending to a fall of potential on an increase of current, and thereby giving stability to the current on the circuit, or particular devices—such as reactive coils, constant-current transformers, etc.—may be inserted between the connections from the stationary windings and the commutating devices, and a transformation of potential up or down may be at the same time accomplished if transformers are employed. While the machine is thus primarily adapted to work a number of circuits of arc lights, it may be on occasion employed to operate three-phase motors or three-phase lighting circuits, or may be used in various transformer combinations to operate two-phase or other polyphase systems.

MUNICIPAL TELEPHONY.*

BY A. R. BENNETT.

(Continued from page 561.)

In estimating the cost of working the Trondhjem exchange it is necessary to explain that the Town Council has no wayleave charges to bear. It uses the townsmen's roofs by agreement, but in every case at present the proprietor is content with his roof being kept in repair, and exacts no annual payment. Of course, it is a serious matter to keep so many roofs in good order, but certainly the Trondhjem Town Council is exceptionally fortunate in escaping money payments in addition. In another respect the Trondhjem Municipality is more fortunate than telephone undertakers in this country—the 10 per cent. royalty payable to Government on exchange telephone subscriptions has no existence in Norway. Not that 10 per cent. added to the Trondhjem tariff would make much difference. The average payment would then be £2. 19s. 9d., instead of £2. 14s. 4d. Even a 10 per cent. royalty only assumes alarming dimensions when the subscriptions on which it is levied are high.

The switching arrangements at Trondhjem at present consist of eight 100-line boards by Ericsson and Co., Stockholm. There are no special features about them. The ring-off drops are connected in the cords in the usual way. This arrangement is somewhat antiquated, and will next year be superseded by a multiple board. A cross-connecting and lightning-guard board is also provided, the lightning-guards being of carbon blocks lying on a carbon plate in connection with the earth, and kept from contact with it by strips of mica. All the work in the exchange has been carried out with excessive neatness, and there is no suggestion of cheapness or neglect about the place.

The second instance of municipal control of telephone systems in Norway is that of Christiania. In my work on "The Telephone Systems of the Continent of Europe" I give full particulars of the Christiania Telephone Company, which has been a most successful concern. On an inclusive subscription of £4. 8s. 11d., it has for many years past paid a dividend of 5½ per cent. per annum on the capital invested after putting aside large reserve funds, writing off values of buildings and system, and providing benevolent funds for its male and female employés. The accounts given in my book for the years 1893 and 1894 bring out these details very clearly. At the end of 1894 the company possessed 4,627 exchange lines in Christiania and its immediate suburbs, in addition to being owner of a large system of trunk lines connecting Christiania with the neighbouring towns in every direction. At the end of September, 1895, the number of exchange lines had increased to over 5,000. The management of the company is invested in four directors, who meet every week, and a managing council consisting of 14 shareholders, which meets every month. This council is elected by the general body of shareholders, and in its turn elects the four directors. The Town Council, which owns a proportion of the shares, is represented directly on the board of the company by three town councillors, one of whom is a director, and the other two members of the managing council. The Municipality consequently exerts a great influence on the company's policy, which is to provide the best possible communication at the lowest rates commensurate with the payment of a fair dividend to the shareholders. The Town Council's share of the capital is contributed out of the rates, but as a return of 5½ per cent. is obtained on it, the ratepayers have no cause for discontent. The outside construction and the particulars of the subscribers' instruments have been fully described in my book, but the original multiple switchboard has just been replaced by one of largely increased capacity and of the most modern type, which switchboard was brought into use only last month. Although the number of subscribers in Christiania is so great, the rate at which new ones join continues undiminished, and it has therefore been necessary to provide for a very large additional number.

About two years ago a party in the Norwegian Parliament suggested that the State should take over the whole of the telephone companies, and a committee, consisting of the director of the State Telegraph Department and several other telegraph officials, together with two telephone managers, was appointed to examine the proposal. The committee, which was, of course, an ex-parliamentary one, reported in January, 1894, by a majority in favour of the State acquiring all the telephone exchanges, as well as the existing trunk lines; but there was also a minority report, which recommended that the State should only acquire the long trunk lines, leaving the local exchanges and the shorter trunk lines—that is to say, those connecting neighbouring towns—in the hands of the private companies and municipalities already working them. When the report of the committee was published, the Norwegian telephone companies and municipalities owning telephone systems formed themselves into a Defence Association, and after holding two meetings in Christiania, at which most of the companies and municipalities were represented, an energetic protest against the report of the committee was presented to Parliament. The contention of the Defence Association was that the State was not in a position to meet local requirements so well as local companies or municipalities could do, and so there would be danger of the great telephone progress which has hitherto distinguished Norway being arrested by the formulation of rules not adapted for the wants of particular localities. The Defence Association also considered it probable that the State would not be able to manage so economically as the various companies do, and that an increase on the very moderate existing rates would be found indispensable. The justice of this view was borne out by a proposal which had been made by the friends of State acquisition as soon as the report of the committee had become known, that the telephone subscription in Christiania, which for many years past has been £4. 8s. 11d. and has proved sufficient, as I have already stated, to return 5½ per cent. dividends regularly, should be increased to £5. 11s. 1d. The Defence Association adopted the minority report, and recommended that the local exchanges and the short trunk lines should be left in the hands of their present owners, while the State should acquire the longer trunk lines, which more nearly approximate to the character of telegraph lines. For two sessions no action was taken on the report of the committee, the number of the advocates of State acquisition being estimated at only about 20 per cent. of the members of Parliament, but just before the conclusion of the last session, in July, 1895, the permanent

Parliamentary Committee which controls the posts, telegraphs, and railways (which permanent committee consists of 15 members of Parliament) recommended that the Government should adopt the minority report of the original committee, and thereupon the Ministry decided that the Government should acquire the longer trunk lines only, leaving the local exchanges and shorter trunk lines, as they are at present, in the hands of municipalities and private companies. Private or municipal enterprise has, therefore, been definitely left in Norway to deal with the telephonic question, and from the energy and technical skill which the Norwegian telephone engineers have exhibited in the past there can be no doubt of the result; and it may be assumed that Norway will continue to develop her telephonic system to an extent of which most people in this country have no sort of conception.

There can be little doubt that State telegraph departments are not the best managers of telephonic facilities. In my paper read before the British Association at their recent Ipswich meeting, I gave many statistics and particulars on the progress of telephony in the chief European countries, from which it appeared that the greatest development and the lowest rates, together with the most liberal concessions to the public, are coincident not with Government control but with private enterprise. This view of the case has, since the meeting at Ipswich, been confirmed independently in a very singular manner. You have before you two maps—one of Jutland in the kingdom of Denmark, and the other of the province of Schleswig-Holstein in the empire of Germany, immediately to the south of Jutland. You will perceive that Jutland is covered by telephone exchanges, there being scarcely a village not possessing one, while trunk lines, shown in red on the map, connect all these together, and cover the country with a very network of wires. If you look now at the map of Schleswig-Holstein you will see that there are scarcely more than half-a-dozen telephone exchanges, while the trunk consist of one route running north and south from Flensburg through Kiel to Altona, with a branch to Rendsburg. The Chamber of Commerce of Flensburg, one of the chief towns of Schleswig-Holstein, has recently forwarded copies of these maps to the Imperial Government in Berlin, pointing out to the Government what I am now pointing out to you, that in Jutland, where telephonic enterprise is entirely in the hands of private companies, the country is covered with telephonic exchanges and telephonic trunk lines; that subscribers there are never charged more than £4. 3s. 4d. per annum, while in the majority of cases the charges do not exceed from £2. 10s. to £3. 10s. per annum. But in Schleswig-Holstein, south of the Danish frontier, the telephone system is in the hands of the Imperial German Post Office, with the result that, although the country is much richer and better populated than Jutland, telephone exchanges are few in number, possess few subscribers, and are infinitely worse off than the Danish in respect to trunk line communication, while the annual charges are never less then £7. 10s. per annum. The Flensburg Chamber of Commerce present these facts to the Imperial Government, and petition that measures may be taken to improve the development of telephones in Schleswig-Holstein, and especially that the present excessive charges should be reduced, pointing out that the social and physical conditions of Schleswig-Holstein are practically the same as those of Jutland, and if the rates of between £2. 10s. and £3. 10s. are remunerative in Jutland, they should be made equally so in Schleswig-Holstein. With the petition was forwarded a list of some of the Danish companies, giving particulars of their capital, number of subscribers, and dividends, from which it appears that the last range from 5 per cent. to 16 per cent. A more apposite and striking example of the differences between the management of Government departments and the results which follow the application of local intelligence, skill, and the employment of local capital, it would scarcely be possible to find, for only a few years ago Schleswig-Holstein belonged to the kingdom of Denmark, and was practically, what it still is geographically, a part of the peninsula of Jutland. Had it remained Danish, Schleswig-Holstein would doubtless be to-day as well telephoned as Jutland is, for private enterprise would not then have been throttled by Government monopoly. The German Telegraph Department is a highly organised concern, but it suffers from over-centralisation. The headquarters are in Berlin, and nothing can be done, however trivial, in any town or village in Schleswig-Holstein, or any other part of the vast territory controlled by the department, without previous consultation with and permission obtained from Berlin. Local conditions are ignored, and the smaller towns and villages can only obtain telephonic facilities by guaranteeing the Post Office, over whose management they have no control, against loss.

It must not be supposed that low rates are peculiar to Norway. Of the 31 exchanges in Holland all but three enjoy rates ranging from £4. 19s. 1½d. per annum down to £2. 9s. 7d. per annum, and these rates have proved remunerative to the undertakers. Sweden, Denmark, Switzerland, Luxemberg, and Finland afford additional examples of cheap telephony. But what experience have we in this country calculated to show that these low rates are as practicable here as on the Continent? A good deal if we examine the history of the last 15 years.

The rate of the Dundee and District Telephone Company was £5. 10s. per annum for any distance, and it paid an average dividend of 9 per cent. during the four and a quarter years of its existence. To buy it out the National had to return its capital with 40 per cent. added, besides paying bonuses to the chief officials. The cost of the lines erected by the company was £15 each. The Sheffield Telephone Company paid good dividends for many years on a £7 rate. The Sheffield people still enjoy better terms than the other large towns, since when the National Company acquired their system they were enabled, by threatening to call in an opposition company, to stipulate for a special tariff, which is still in force. The tariff is as follows:

	Per annum.
For distances not exceeding 1½ miles.....	£8 0 0
For distance not exceeding two miles.....	10 0 0
For each additional half mile beyond two miles	2 10 0
For private houses not exceeding two miles.....	7 0 0

These are much lower terms than those current in Manchester, Liverpool, or Glasgow, yet, as they exist, we may be sure that they are remunerative.

The Globe Telephone Company, which commenced an opposition exchange in London at £10, was bought over at an early stage in order that the monopoly rate of £20 might be maintained; the same fate subsequently overtook the New Telephone Company, which obtained 3,600 subscribers in London at a £12. 12s. rate. Such an enterprise would have been fatal to the National Company's London exchange, and had to be bought up regardless of cost.

But the best and most recent example occurred in your own city of Manchester, where the Mutual Telephone Company constructed an exchange in 1891 at rates which varied from £5 for shareholders in the company to £6 for non-shareholders. The Mutual Company introduced many improvements, and gave a service which was, I believe, unanimously regarded as much superior to that of its rival. The cost of connecting the Mutual subscribers by double wires was £16. 16s. each; the average subscription, after deducting 10 per cent. for Post Office royalty, was only £4. 12s. 2d. per line, a figure which approximates closely to the average receipts in Christiania; and yet after putting aside 5 per cent. on the capital expended for deterioration, paying directors' fees, and all working expenses, sufficient surplus was left to pay a dividend, had it been so desired, of 2·29 per cent. per annum. This was in the third half-year of the exchange's existence; subsequently the revenue increased rapidly, and with it the profit. At one time the Mutual Company had 1,389 lines working, but such a formidable rival could not be tolerated. The National Company got possession, and the exchange will shortly be a thing of the past, although about 1,000 lines are still connected to it. Soon those subscribers who for the last five years have been paying from £4 to £6 for a good service will be called upon to pay £10 per annum, or go without telephonic communication.

There is only one other aspect of the situation to which I shall call attention before concluding. It is the woeful effect which the existing monopoly is having upon our electrical industry. Abroad, immense quantities of telephonic apparatus are required to meet the rush of subscribers, and everywhere in France, Germany, Belgium, Switzerland, Sweden, Norway, we find extensive factories already in existence which are devoted entirely to the production of telephonic switchboards and apparatus, and more are continually coming into being. At Christiania I was shown a large building, still incomplete, which is being erected to meet the rapid extension of the Norske Electrisk Bureau's telephonic business. We have nothing of the kind in this country. Why? Because all important orders for instruments and switching apparatus are, and always have been, placed abroad, principally in America, and as a consequence no development of a British telephonic instrument industry has been possible. It is true that the Mutual Telephone Company used practically nothing but British-made apparatus, not because it was British only, but because it was of better design and better construction; but that was only a small indication of what would occur if telephones were free. Let those who have had experience of the rival systems in Manchester say which has given the most satisfaction—that of the National Company, whose apparatus is exclusively American, or that of the Mutual Company, whose apparatus was nearly exclusively British. The suppression of the existing monopoly in telephone exchanges would not only give the subscribers reduced rates and better service, but would practically create a new home manufacturing industry, for the prejudices which at present divert the orders for apparatus into foreign channels would not, it is to be hoped, hold sway with municipalities or with many competing companies.

Furthermore, the freeing of the telephone industry would provide an outlet for much of the surplus capital of the nation, which is now locked up for want of legitimate fields for employment, or, what is worse, is lent to unstable foreign states, or

Digitized by Google

devoted to the development of foreign countries. Much has been heard lately of the absolute necessity of opening up new markets in Africa and elsewhere, but we have at hand a means of employing at least some of our surplus capital at a profit; of finding work for thousands of electricians, of artisans, of clerks, and of labourers; of, in fact, as I have already stated, creating a new and extensive home industry. That means is the reversal of the existing policy of telephonic monopoly.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

LECTURE I.

(Continued from page 533.)

Physical Nature of the Arc.

I ventured, in a lecture I gave here in the year 1889 on the mechanism of the arc lamp, to make some remarks about this phenomenon. I began, however, from the optical point of view, from the researches of Captain Abney, which will engage our attention next week. Captain Abney had found the white surface of the luminous crater to be always of an equal degree of whiteness, which obviously means that it is always of an equal degree of temperature. No matter whether the current going through the arc is small or large, using big carbons or little ones, or whether the arc is long or short, the whiteness of the crater surface is always alike, and therefore of the same temperature. With large currents the area of the crater surface is large; with small currents it is small. Its quantity, but not its quality, changes when the current is altered.

I suggested at that date that the true explanation of this constancy in the intrinsic luminosity of the crater surface was that its temperature was fixed by physical conditions. It appeared that, whether the current was large or small, the temperature at that surface could not rise and could not fall; that it was, in fact, as fixed as the temperature at which ice melts or water freezes. The only thing that could account for there being a fixed temperature for the crater surface was the fact that the carbon is at that surface in a state of volatilisation; that the carbon is evaporating off from the positive carbon into the arc or flame†. At that surface you necessarily must have the temperature at which carbon evaporates, just as you cannot have the surface of ice under ordinary conditions either hotter or colder than the temperature which is taken as zero of the centigrade scale. If you take a piece of ice and put it in front of the fire, the ice itself does not get any warmer; it simply melts off at the surface, the surface of the solid remaining equally cold as before. So the surface of a piece of a carbon, when in contact with its own vapour, must necessarily be at that fixed temperature. That seems to be now the generally accepted idea.‡ I want now, however, to go a little further, and to suggest another idea to you.

It was found by Deprez, about 1850, that carbon just before it volatilises, becomes very soft—in fact, he obtained good evidence of plasticity in carbons when heated up to very near the temperature of the arc. Now, that means, of course, that there is, any rate, an incipient liquefaction going on a few degrees below the temperature of the volatilisation. Now, the temperature of liquefaction will also be a fixed temperature. If you have a film of literally liquid carbon lying on the top of solid carbon there must be a fixed temperature where they come together at the surface where the carbon is melting. There is some evidence that such films exist over the crater surface; but the temperature of the visible surface of the crater is the temperature at which solid carbon volatilises. My present view of the physical state of the arc crater is that the solid carbon below is covered with a layer or film of liquid carbon, just boiling or evaporating off.

The Hissing Arc.

When hissing takes places, a new state of things is set up. If you watch a short hissing arc you will see a column of light concentrating itself on a narrow spot, and that spot keeps moving about, and is very unstable in position as well as in the amount of light it gives out. The contracted spot from which the light seems to start pits deeper into the carbon. I think the first mention of this pitting effect of the hissing arc is not recorded anywhere yet, unless it was mentioned by Prof. Ayrton in 1893 in the paper he read at Chicago, which has never been published. I myself derived the information from Mrs. Ayrton, who made the observation that the crater surface, after the arc has been hissing, is found to be literally honeycombed. When the arc is hissing you can see little bits erupted out, and the hissing seems to be comparable to the hissing which takes place in water just when it is beginning to boil. If you have some water being heated in such a way that there is not more than a certain quantity of heat given off from the surface, you have the water evaporating quietly, but you cannot get more than a certain quantity of heat given off per square inch of top surface of the water in that quiet way. If you force more than a certain quantity of heat to pass off per top square inch of the water, you find the water begins to break up internally, and you have bubbles formed below the surface, the surface breaks up, the bubbles are thrown out, and you have a noisy phenomenon. I think you will find there is exactly the same kind of difference between the silent arc and the hissing arc as between quiet evaporation and noisy boiling. There is a sort of decrepitation, as though solid particles were being torn asunder to make way for something coming out, when the arc is hissing.*

Location of the Back E.M.F.

Another point which remained doubtful for a long time, even after Edlund had made his observations, and these measurements had been made, was whether this fixed voltage that appears in the arc was really the back E.M.F., as Edlund supposed, or whether it was a "transitional" resistance—a sort of resistance located at the surface of transition which, instead of being a constant, as resistances usually are, varied inversely as the current. That was, indeed, Schwendler's view. Schwendler said here is a resistance which varies inversely as the current; when you double the current, the resistance goes down one-half, therefore you want exactly the same voltage as before to drive that double current through. After all, it may be only a *façon de parler* to call this by either name, but at any rate reasons can be adduced in favour even of so improbable a view. Suppose there is a surface between a solid on one side and a vapour on the other. Apart from any question of evaporation going, or matter being given off from the solid into vapour at that surface, there is at that surface a difficulty in the current getting out from the material in one state to the other; that resistance will be, other things being equal, inversely proportional to the surface. One square millimetre of surface will offer a certain amount of difficulty; with two square millimetres you will have two possible paths, and the difficulty of transition will be halved. If there is anything that goes by area, then, if the resistance is transitional, as it is supposed to be, it will vary inversely as that area. Is there anything that goes by the area? Yes, the size of the arc which determines the size of the crater—I mean the cross-section of the arc is found to be almost exactly proportional to the current. If by any possibility you alter your current and pass twice as much current as before, I do not say it will burn equally steadily, but you will find the crater's area will be almost double. This observation was made a long time ago by Mr. J. D. F. Andrews, and is recorded in the *Journal* of the Society of Telegraph Engineers. If, then, the current produces a crater proportional to itself, and the transitional resistance varies inversely with the crater surface, it will vary inversely with the current, and the effect will become the same as though there were a fixed E.M.F. But I do not think that is the true explanation, because I do not believe in this transitional resistance. It seems to be a way of explaining a thing by introducing something which is much less understandable. When you have come to this explanation, you have to explain the transitional resistance; but you can explain and see the reason for a counter E.M.F. Whenever work is done by a current in a circuit, it is always done by virtue of a back E.M.F. The fact that there is a back E.M.F. in a motor enables you to utilise the electrical energy. The fact that there is a counter E.M.F. in an accumulator that you are charging enables you to store chemical energy in it. The fact that there is a back E.M.F. in an arc enables you to do work in that arc. If there is a back E.M.F., it ought to have a definite seat. Has it a definite seat? Where are these 39 volts? Are they at the crater surface? Are they distributed all along the arc? Are they at the negative peak? That was one of the points which was entirely uncertain until a few years ago. Several of us have worked at it, Prof. Fleming and Prof. Ayrton amongst others. An observation which I made some years ago was communicated to the Electrical Engineers at the time. I made an arc in the usual vertical way, with the positive carbon at the top. In Fig. 4, in order to plot volts vertically against lengths horizontally, the arc is represented as turned over on its side, and the distance between positive and negative electrodes is greatly exaggerated. Into the space between the crater and the peak I then introduced a third carbon to act as an explorer. The difference of potential between the two points, as measured with a voltmeter, was about 45 volts; and to measure this the wires of the voltmeter must be connected, the one to the negative, the other to the positive carbon. But if one wire is connected to the negative

Digitized by Google

carbon, and the other to the third or exploring carbon, one is enabled to go fishing about to find how this 45 volts of potential difference is distributed along the arc. If the arc merely operated as a plain resistance, the fall of potential would be found to be distributed along the length equably; when the exploring carbon had been moved through half the length, the voltmeter would just show 22½ volts. But nothing of the sort is found. At a point half-way along, the potential was found to be about four volts higher than the negative carbon; and as the third carbon was moved towards the crater, this rose to nearly six volts. This process, then, enables one to locate the whereabouts of these 39 volts of back E.M.F. Suppose one plots out vertically the results of the observation, as in Fig. 4, the high-level line to represent the potential of the positive carbon, the low-level line the potential of the negative carbon, then the volts drop from high to low, somewhere or other in the distance from crater to peak. We might, of course, have measured the voltage drop from the positive carbon downwards, instead of measuring it from the negative carbon upwards. This method of exploration is precisely similar to that known and used for years in examining the polarisation of secondary batteries. Inspection of the diagram that has been plotted from the observations shows that there is a drop of something like 39 volts at the crater, and then there is a slight regular drop all the way down the arc, due to the fact that there is current going through resistance; then there is a slight drop at the other end of the peak. I measured that slight drop to be two or three volts; but in one case, where the arc was hissing, I found at that place a slight rise. Other observers* have also obtained a rise at this end, showing that some inverse phenomenon is going on there. The same kind of thing occurs frequently in electrolytic observations. One finds the potential of the intermediate liquid lower than that of either of the materials at the two ends.

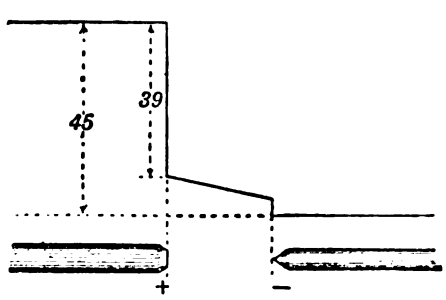

FIG. 4.

If there were a hissing arc instead of a silent one, the drop at the crater would be found to be only about 13 volts there, and the whole voltage from one side to the other would be very much less. Many years ago the observation was made by M. Niaudet that the current, if supplied under certain conditions, increases at the moment when the arc begins to hiss; if supplied under certain other conditions it, however, decreases at the moment when the arc begins to hiss. This apparent back E.M.F. has not only been a puzzle to the investigator, but it has led to several fallacious suggestions. There is a remarkable paper in the *Comptes Rendus* for 1884, by the late Prof. Jamin. Jamin was an intelligent man, but he formed this extraordinary opinion that an alternating-current arc would necessarily be much more efficient than any arc could possibly be when produced by a continuous current, whether from a battery, an accumulator, or anything else. For, said he, if you work with a battery or an accumulator, that current always flows in one direction, and you have 39 volts against you—that means a pure loss of energy, which is thrown away; whereas if you work with a rapidly alternating current, the back E.M.F. will help you at each reversal of the current. Therefore, the alternating current will be very much more efficient. Of course, the whole thing is a mare's nest. Jamin did not understand that the essence of getting work out of a current, whether from a motor or an arc, was to have back E.M.F.

Another matter which has never yet been properly cleared up is the transport of matter across from one side of the arc to the other. Unquestionably in a hissing arc there is a large transport, particles of carbon in solid or liquid state being visibly projected across the gap to form the mushroom on the negative peak. Besides this bodily transport, there is probably also a molecular transport by evaporation at one side, and condensation at the other. But the hissing arc is not the normal phenomenon, and the transport of actual particles is abnormal. In a silent arc there is very little. You may, in fact, substitute as a negative pole a piece of metal, if you keep it cool and prevent it from melting. The evaporation of carbon at the positive surface is quite sufficient to keep the arc going. However, some researches have been made on this point. Sir William Grove thought he got a transport in both directions, as did Matteucci, who employed, instead of carbon, a pole of iron and a pole of copper. On examining the two surfaces after an arc had been allowed to play across, he found that some carbon had been carried over to the iron, and some iron had been carried on to the surface of the copper. But the spluttering effects one gets when using metals in this way make one very unwilling to accept such results as conclusive. A recent experiment of M. Blondel in photographing the image of the arc proves, if anything can prove, that there is only one direction in which material is ever transported, and that is from the positive side to the negative, from the crater to the peak.

ALTERNATE-CURRENT ARCS.

I have the means here of showing an alternating-current arc. We will turn on the current from the London Electric Supply Company, and I will show the alternating arc first by means of one of those nearly obsolete devices, one which has now become almost a museum curiosity—a Jablochkoff candle. All honour to Paul Jablochkoff. In the year 1877, he revived this elementary method of providing for an arc; avoiding all mechanism, by simply putting the two carbon pencils parallel at a suitable distance apart, one by the side of the other, with a bit of plaster between. On switching the candle into circuit, the alternating current passes from one point to the other after being started by a temporary bridge-piece. Jablochkoff used the alternating current, simply because it was essential that the consumption should be equal at both tips. In the use of the alternate current the actions at the tips reverse at every reversal of the current. For an instant the current flows in one direction, then reverses, only to reverse back again. For a brief time the crater will be forming on one tip, and the negative peak on the other; then a very small fraction of a second afterwards the action is reversed, and so the two carbons are consumed away at equal rates. But, for my own part, I do not admire the light from the Jablochkoff candle. It always roars and hums because of the alternations that are going on. The light is down in a hole between two carbons, so that it is not diffused in the most satisfactory or economical or agreeable way.

HIGH-VOLTAGE ALTERNATING ARC.

While I have an alternating current here I should like to show you another arc phenomenon that is not often seen, at any rate, outside electric lighting stations. I refer to the alternating-current arc at 2,000 volts. The arc that one gets from a current when elevated to such a high E.M.F. as that will be very much more like that which Davy produced with his charcoal points and his battery of 2,000 cells. That is to say, it will be a real arch of flame between two points, and this arch will be blown upwards by the ascending current of air. You will notice that the whole arch itself is more or less luminous. You will see that we get great roaring flames, but you will be astonished to find how little carbon is consumed by this 2,000-volt arc. In fact, the higher one goes in voltage with the arc the less carbon is consumed, and in some cases the less light you get. But the consumed carbon is very small, and these flames appear to be rather of the nature of true flames. Only there is this difference: instead of taking combustible materials, putting them together and burning them in order to get out heat, you are taking materials which do not ordinarily burn together—viz., the two constituents of the air, nitrogen and oxygen—and you are forcing them to burn together by pumping heat into them. It is an endothermic flame, instead of the ordinary exothermic flame. It is a flame which takes in heat from the current, which requires to be fed with heat, in order to exist at all. Certainly some of the luminous phenomena one gets with high voltage and at high frequencies are of this nature, and therefore are not like the true arc. In the arc itself, when made in the air, undoubtedly there is a combustion of the air—that is to say, the oxygen and nitrogen of the surrounding air are burnt together by the heat, and also both of them combine with carbon.

CHEMISTRY OF THE ARC.

The chemistry of the arc has never been thoroughly worked out. Prof. Dewar, amongst others, has worked at it and shown that not only do you have carbonic acid and carbonic oxide produced, but nitrogen compounds, prussic acid, cyanogen, nitrous acid, and various others. He drew off the gases through tubular carbons and analysed them.

I do not think anyone has in any record called attention to the smell of the arc lamp. The arc certainly has a very characteristic odour, probably due to the fact that the carbon is combining both with nitrogen and with oxygen, and that the nitrogen and the oxygen are combining together, giving rise to compounds which, though more or less poisonous, are happily produced in very small quantities, and give a decided odour to the air where an arc is being made. These flaming arcs, at high voltages, very soon produce a perceptible odour: whereas a normal arc, produced actually by 40 to 50 volts, gives very little smell indeed, and sets free extremely little of the disagreeable nitrogenous products.

Magnetic Properties of the Arc.

Amongst the early things that Davy discovered was the effect of a magnet on the arc. He showed that the arc behaved like a flexible conductor, and a magnet being put near it caused it to bend to one side or the other. If the current in it is ascending, it is bent to one side in the magnetic field; and if it is descending, the arc is bent to the other side. In the case of the horizontal arc, it makes a difference whether the current is flowing eastwards or westwards: in the one case, the earth's magnetic field tends to bend it up, and in the other case it tends to bend it down. As a consequence, you can get a larger maximum length of arc with a given current, if the current comes in at the east and goes out at the west, than if it comes in at the west and goes out at the east. Also, with an alternating-current arc, where the current flows alternately up and down, the flame of the arc is literally pushed on one side. If you examine an alternating-current arc in a mirror that rotates round a horizontal axis so as to get a succession of images thrown out vertically, you will find that those images are successively curved right and left, owing to the effect of the earth's magnetism. Walker and De la Rive observed the arc to rotate round a magnetic pole, and a number of kindred experiments have been made which are very curious. I will only show you one. Here is an electromagnet which I can introduce into the circuit. I will take a pair of carbon pencils, and placing them between the poles of the magnet, I will try to obtain the arc, using 40 or 50 volts in the arc circuit. You know that ordinarily the arc goes out if the carbons are parted too far. When it does go out it does not make much noise; there is a slight sound like that heard when a candle is puffed out. But try it between the poles of that magnet, what do you find? You cannot even get the arc to keep alight. It flops out instantaneously with a sound almost like a pistol shot. The flame is blown inwards or outwards, according to whether the current is flowing down or coming up. You notice that I put one carbon at the top and the other at the bottom, and then the magnet blows the flame outwards. If I reverse the carbons and put the negative at the top, the flame will be blown inwards. Even if one works at some distance away from the poles of the magnet you still observe this very peculiar effect. To burn the arc steadily in a strong magnetic field is almost impossible. If I had a larger E.M.F., say, 300 or 400 volts, so that I could support a long flaming arch between those two carbons, and were to form such an arc, it would be blown out sideways, like a blowpipe flame. This was observed long ago by Quet in 1852, and in 1874 by the late Mr. Werdermann, who proposed to employ it as a sort of blowpipe. He set two carbons side by side like a Jablochkoff candle, and arranged a magnet to blow out the flame in a long tongue, for use in soldering or lead-burning, instead of a blowpipe. Recently others have combined magnets with arcs for the purpose of making electric blowpipes. The Benardos process of electric welding and forging is based on this particular use of the arc.

(To be continued.)

WORM-GEARING IN CONNECTION WITH ELECTRIC MOTORS.

In a paper read before the Electrotechnischer Verein of Vienna,* Mr. Ernst Egger described, with the aid of illustrations, various kinds of of electrically-operated elevators. The author stated that when worm-gearing was employed for transmitting the power direct from the motor shaft to the drum it was particularly advantageous to use low-speed motors. This expression of opinion has elicited a response from Mr. Emil Kolben, of the Oerlikon Works, who contradicts this assertion.

In correcting this erroneous idea which has generally been held, Mr. Kolben states that high-speed motors should be exclusively conducted in conjunction with worm-gearing, if the work is to be commercially practicable and a good efficiency realised. It is from this standpoint that the question is of importance to electrical engineers, since, although no particular difficulties are met with in the construction of motors to run at low speeds, yet the motors are heavy, bulky and expensive, so that the use of such motors in many cases is excluded. As, on the one hand, the employment of worm-gear is regarded with great mistrust, and yet, on the other, this kind of gear is the most important reducing mechanism for electrically-driven tools, cranes and lifts, and for vehicles, Mr. Kolben thinks it right that some facts should be adduced for the benefit of the electrical industry.

Proceeding to deal with this question, the author points out that a great predjudice against worm-gear has hitherto existed, on account of its having been regarded in the old text and hand books as an inefficient means of transmission; and not unjustly so when the method of constructing the gear is considered. After referring to the work in this direction by Profs. Thurstone and Kimbal and Mr. Towne in the United States, and by the late Mr. A Reckenzaun, who obtained an efficiency of 87 per cent., and subsequently by Mr. Sellers in Philadelphia, the author discussed the efficiency tests recently carried out by Prof. Stodola, of the Zürich Polytechnic, with the ordinary double-thread worm-gear of the Oerlikon Works.

The worm was 3⅛in. in diameter, had a multiple-ring bearing and engaged with a worm-wheel having 28 teeth, the wheel being of bronze, 14¾in. in diameter. The whole of this gear was placed in oil in a cast-iron box. The gear was coupled to a 20-h.p. electric motor, and the braking tests were made on the worm-wheel shaft. The results were as favourable as in the case previously mentioned. At 1,500 revolutions, a useful performance of 21 h.p. was given on the brake, the efficiency amounting to 87 per cent. The author, who had previously conducted a series of experiments which agreed with the result above cited, is of opinion that the efficiency with the motor fully loaded will increase even beyond 80 per cent., if the following points are considered in the construction and fitting up of the gear for direct coupling with electric motors.

(1) The starting speed should, according to the output, amount to from 20ft. to 40ft. per second, instead of from 7ft. to 16ft., as has hitherto been customary. This condition necessitates the use, not only of high motor speeds, but also of a large diameter of worm, and consequently great distances between the teeth, powerful teeth, and ample bearing surface. By this means the total friction will be reduced. For the purposes mentioned the motors required range from 2 h.p. to 25 h.p., with usual speeds varying between 1,600 to 800 revolutions a minute. As the elevator drums to be operated, the driving spindles of machine tools, and the car axles of tramcars have speeds of from 150 to 40 revolutions a minute, it is possible to obtain in the most simple manner, without any intermediate gear, the whole speed reduction by means of worm-gearing, with a single or double thread worm having a ratio of reduction of 10 to 1 or 20 to 1.

(2) The mechanical production of worm gear requires the greatest care, if it is to be useful for the direct coupling of motors. The worm must be turned out of a solid piece of tool steel, and be tempered, smoothed, and polished. The crown of the teeth should be made of hard phosphor bronze, and if of large diameter it should be drawn hot on to a cast-iron arm crown. The teeth are to be properly cut and polished. The whole gear is to be closed in a box and allowed to work in an oil-bath. This arrangement will reduce the friction coefficient between steel and bronze from 0·01 to 0·005. Gear constructed in this manner runs noiselessly, has only a slight wear, and a life of several years.

(3) In order to reduce to a minimum the friction of the whole mechanism on the starting of motors at full load, the pressure is taken up by starting discs arranged on both ends of the worm.

HEATON AND CO.'S ELECTRICAL FITTINGS.

Messrs. Heaton and Co., of Salford Switch Works, Salford, Manchester, have lately submitted to our representative samples of electrical fittings which embody several good points, both of construction and design. This is especially the case with their switches, three forms of which we illustrate.

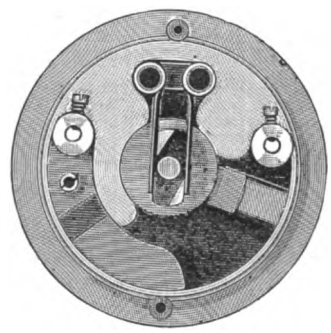

Fig. 1.

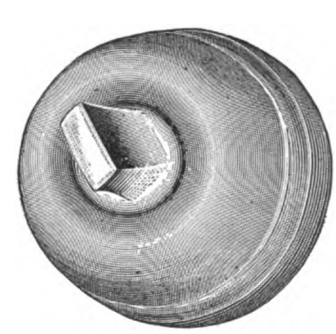

Fig. 2.

Figs. 1 and 2 give interior and exterior views of the "A" type "thumb" switches, which are stocked in three sizes for currents of respectively 5, 10, and 15 amperes. The base and cover are of either white or black porcelain. The chief point about this switch is the steel wire controlling spring, which bears on the lozenge-shaped boss on the spindle. The spring, wound in one piece and mounted on two studs, has two "prongs,"

Digitized by Google

as shown (Fig. 1). The advantage of this is that the strain is distributed between them, and in the thus reduced likelihood of one "prong" breaking, the other still acts: and, owing to the special method of mounting, with renewed strength. The switch, therefore, as compared with most others, has two "lives," so to speak. The porcelain handle fits loosely on to the boss above-mentioned, so that the switch will spring off independently of the handle, and the latter is removable with the cover, enabling the parts to be easily inspected and cleaned. One terminal, the spring, and the movable tongue are all mounted on a common brass base, and when the switch is "on" the thickened end of the tongue wedges in the gap between the bottom brass base and the upper brass plate connected with the second terminal, so that good contact is secured. In the figure, owing to a draughtsman's error, the holding-down nut, screw-holes, etc., are shown too small. These switches can be supplied with removable key handles, and with fluted brass or decorated covers.

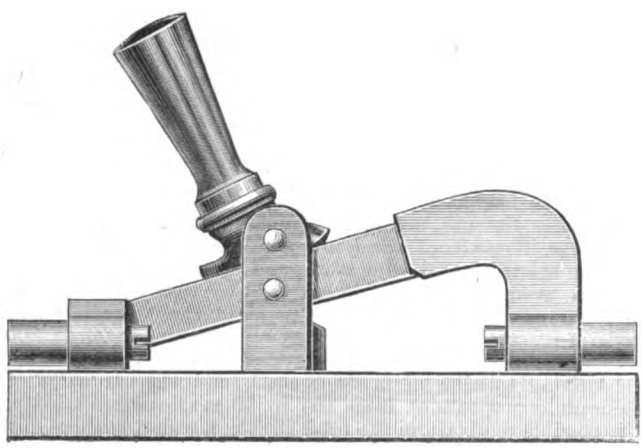

FIG. 3.

A neat form of double-pole double-break switch on square slate base, in square polished brass or teak case, with ebonite handle, is claimed to be the smallest D.P. switch on the market, it being stocked in sizes from 5 to 50 amperes. This is known as the "D" type switch, and is certainly very simple and substantial in construction. Two-way five-ampere switches of this design are useful for controlling the same lamp or lamps from two points; the method of wiring being such that the same lamps may be turned "on" or "off" at either switch, or "on" at one switch and "off" at the other.

Fig. 3 illustrates the "L" type double-break main switch for currents of from 25 to 400 amperes. The movable contact lever is pivoted on the centre upright, and is formed of two thick copper strips about ¼in. apart, fixed together by a short piece between them at the point where they are hinged. On the underside, just below the pivot, is a protruding portion on which the upper end of a strong coiled spring sunk in the base

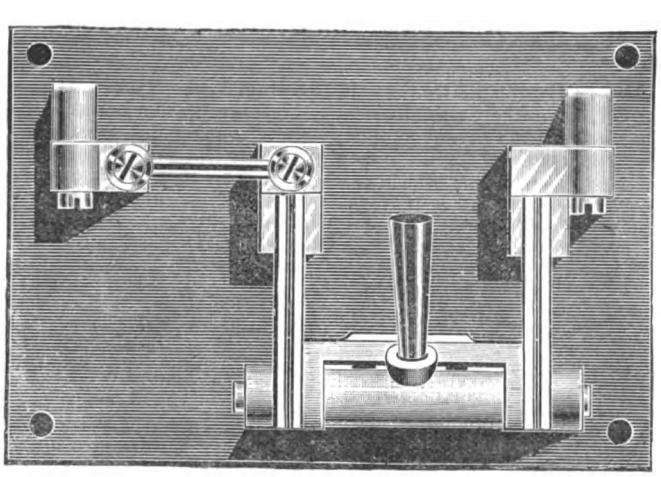

FIG. 4.

acts, forcing and keeping the lever in either the "on" or the "off" position. The switch handle is hinged independently of and just above the contact lever. In the figure the switch is shown "on," and to pull it "off" the handle would be moved to the right. The spring is only compressed during the act of putting the switch "on" or "off," so it is not likely to lose its elasticity. The ends of the lever, which are like those shown in Fig. 4, wedge into similar contact blocks, to which are screwed the sweating sockets. The switch is quick-break, and the parts are mounted on enamelled slate bases, with or without fuse terminals as desired. Switches of this kind can be coupled up in tandem or abreast for double or triple pole work.

Fig. 4 shows a double-break single-pole fuse switch of workmanlike design, and known as the "M" type. It is made for currents from 25 to 200 amperes. The pull-off spring is coiled round the axle and encased in a tube carrying the handle. The copper contact tongues are fixed at opposite ends of a frame, and it will be seen that there is a solid metallic circuit from one contact block to the other. The same type of switch without fuse is stocked, and the sweating terminals are arranged to couple up either above the base, as shown, or below. The parts are either polished and lacquered, or part steel-bronzed and part polished, the bases being of enamelled or paraffin-waxed slate.

Two switches of this type mounted abreast and connected by a stout vulcanite handle bar form a very efficient double-pole switch. These (called the "M D P" type) are made for the same currents as the "M" type. They are supplied, when required, with covers and protruding handles.

The "N" type quick-break two-way switch is useful for coupling either of two dynamos to one circuit, or either of two circuits to one dynamo, and is so constructed as to remain in the central or "off" position when the circuit is broken.

This firm make a form of ceiling-rose with a new and efficient cord-grip. Forming part of each terminal plate are brass holders, bent at right angles. The cord is laid in these, and the latter are pinched in with a pair of pliers so as to effectually grip the cord. The terminal plates are securely screwed to the porcelain base, and all strain is taken off the terminal screws. When it is desired to release the cord, the "grips," or holders, can easily be opened by means of the edge of a screwdriver, etc. Instead of pinching the "grips" on to the cord, a double turn of the latter round them will take all the weight off the terminal screws. The great advantage claimed for this ceiling-rose is that it is quickly wired.

Cord-grips, as above described, are also fitted in a neat form of "triple-suspension ball" for suspending three lamps from one ceiling-rose.

Besides the switches, etc., already mentioned, Messrs. Heaton and Co. make various kinds of cut-outs, and fuse and switchboards, as well as lamp fittings.

Justice needs that both be heard."

THE CONTROL OF ELECTRIC CARS.

SIR,—An incident which happened lately at Havre will be of interest to your readers, as showing how easily an electric tramcar may be controlled and operated. One of the cars was running at normal speed along the street when a child, four years old, suddenly ran right in front of it when only a yard away. The "wattman" (as the motorman is called in France) could not, of course, avoid passing over the child, whose body somehow dodged the fender, but he pulled up the car in *half its length;* and the poor child was safely taken out from under the car through the movable floor panels, with a rather serious wound on the head and suffering from shock, as might be supposed, but alive and likely soon to recover.

It is not very pleasant to think of what might have happened with a steam, cable, or even an ordinary horse car in such a case. There seems little doubt that the child would have been killed at once.—Yours, etc.,

Rouen, November 14, 1895. FRANK B. LEA.

DRIVING SHIPS BY ELECTRICITY.

SIR,—I felt rather surprised that a somewhat unfavourable comment should have been made respecting the note on p. 551 of your last issue—"A Marine Electric Locomotive." The idea struck me as being a very good one, if only to get rid of the everlasting throb of the screw-shaft. So far as engine economy itself is concerned, probably the slow-speed compound condensing Corliss engine proposed for use would not be materially cheaper to work than the present types of marine engines, which often burn less than 2lb. of coal per indicated horse-power, though not on a transatlantic liner. But although the double transformation effects a loss of perhaps 5 to 8 per cent., it must be remembered that the long lengths of screwshaft with bearings, etc., is practically done

Digitized by Google

away with, and even the thrust bearing might be abolished by training the end pressure of the screw more directly against the keel or bottom framework. For such passages as across the Channel or Atlantic, the matter of doing away with vibration is alone well worth a 10 per cent. loss in transmitting the power from engine to screw. I don't envy anyone the task of designing suitable motors, though, for such work as would be acquired.—Yours, etc.,

BAD SAILOR.

HIGH-VOLTAGE LAMPS.

SIR,—In your issue dated November 8, I find there is a notice on the high-voltage lamp manufactured by Messrs G. Straus and Co. The letter therein referred to was forwarded on behalf of the first consignment of lamps received, and not for the pattern illustrated in your notice. This letter has now been incorporated in their catalogue (together with a clerical or printer's error) without my knowledge or consent.

Had they adhered to their original design and quality of lamp, I should not have considered it necessary to call attention to this matter.—Yours, etc.,

SYDNEY W. BAYNES.

REVIEWS.

Recettes de l'Electricien. Collected and arranged by Prof. E. HOSPITALIER, editor of *L'Industrie Electrique*. Illustrated. Price 4f.

General books of recipes are common as blackberries in autumn. Such books are also well known relating only to engineering matters; but as each department of engineering becomes more and more a speciality, a need will probably be found for books of recipes for each special department. M. Hospitalier has given us one for the electrician. Even this traverses a pretty wide field, giving as it does recipes relating to fusible alloys, solders, cements, plating, coil-winding, tools, bands, lubrication, making mirrors, delicate suspensions, batteries, electrolytic work, distribution, jointing, insulators, switches, cut-outs, accumulators, and various other matters connected with electrical work. He also gives what may be called a *résumé* of electric law in France. The selection and arrangement of some hundreds of recipes is a task which can be done in two ways. It may be a mere collection by the aid of paste and scissors—the selection haphazard—or the selection may be carefully done by a man desirous of minimising the labours of those engaged in the industry, who selects with a knowledge of what is good and what is bad. M. Hospitalier is of the latter class; his life has been devoted to the study of electrical matters, and therefore his selection is of the best.

THE ROTTINGDEAN ELECTRIC RAILWAY.

THE APPLICATION GRANTED.

A special meeting of the Brighton Town Council was held at the Town Hall on Saturday last for the purpose of resuming the consideration of the report of the Works Committee with reference to the application of the Brighton and Rottingdean Seashore Electric Tramroad Company for permission to erect poles on the seashore for the purpose of the working of their tramroad.

The **Town Clerk** mentioned that the Borough Surveyor and Mr. Arthur Wright (electrical engineer) were in attendance on behalf of the Corporation, and Mr. Magnus Volk and Mr. St. George Moore on behalf of the company, and these gentlemen were invited to enter the Council-chamber.

Mr. St. George Moore, civil engineer to the company, first addressed the committee. He said he would like first—being responsible to the directors for the due observance of the technical questions in the Act of Parliament—to explain by means of diagrams how he had endeavoured to comply with the provision in the Act that the line should not be more than 4in. above the chalk or sand. As the sand was constantly varying in level, he estimated the true meaning of the words, "not more than 4in. above the sand," to be not more than 4in. above the maximum level of the sand, as otherwise the plant would be worthless and the railway unworkable. Mr. Moore exhibited diagrams showing sections of the sand at four spots east of the Paston-place groyne, a line being taken north and south, and pointed out that in the first case if the sand were levelled the northern rail in the first section would be 3in. above the sand, in the second 3in. below the sand, and in the third 11in. below the sand. There were in the Act of Parliament practically three instructions as to the course to be pursued. The plans were to be approved by the surveyor, there was power of deviation from the plans within certain limits, and the line was to be not more than 4in. above the chalk, rock, and sand. In ordinary railway practice they had been in the habit of using this power of variation, and all he had to say was that, in adopting this custom without submitting fresh plans to the borough surveyor to cover the little variations he found necessary to keep the line 4in. above the level of the shifting sand, he had done it inadvertently, and without any wish to do anything that would offend the Corporation.

With regard to the weight of the car, the engineer who first advised the company said he thought a car weighing about 20 tons would suffice, but he (Mr. Moore) must confess that when he calculated the strength of each individual part of the car, and went into the affair thoroughly, he found that the weight must be increased. The gross weight of the car without the electrical machinery—for nobody knew yet what kind of machinery would be used—was calculated as 35 tons 13cwt. 1qr. 12lb., but there were sundries which might raise the weight to 40 tons, and 150 passengers would weigh about 7 tons 10cwt. The weight of machinery would be 7 or 8 tons if accumulators were used; 7½ or 8½ tons for steam, and about 2 tons for the trolley system. The horse-power required would vary greatly. At low tide, with an incline of 1 in 300 on a 40-chain curve against a 14-mile wind, 24 h.p. would be necessary for a speed of six miles an hour; running with bogies in the water, 40 h.p. would be needed under similar conditions, and with the car submerged, 63 h.p. Dealing with the four motive powers suggested, he said he understood the Corporation objected to the use of steam, while with gas or oil engines at such height above the rails the vibration would be excessive, and in the two latter cases the smell and noise would be objectionable, and there were serious, if not insuperable, mechanical difficulties in reversing and starting the engines. He was not an electrical engineer, and could not go into the arguments for or against the accumulator or the trolley system, but he ventured to point out this and steam were the only two systems which had been tried and proved successful.

Questions were then addressed to Mr. Moore by several members and by the officers of the Corporation. In reply to **Alderman Moon**, who asked whether or not the original weight of the car was 20 tons, **Mr. Moore** replied that the car spoken of as the original one was never designed; it was only a sketch.

The **Borough Engineer** (Mr. May) asked Mr. Moore if it was not a fact that there was no sand now at the spots represented in the diagrams produced. **Mr. Moore** replied that the diagrams represented the highest sand level while the works were in progress. **Mr. May** asked if the parliamentary plans did not show the chalk cut and indented to carry the sleepers, so that the rails were level with the top of the chalk. **Mr. Moore** replied that this was so, but that one section could not be supposed to control rails three miles long. **Mr. May** asked if it was not usual to give plans of any variations rendered necessary. If one section only were submitted would it not be assumed that that applied to the whole of the scheme? **Mr. Moore** said the ordinary practice of fixing a line was a well known quantity. This was a different matter altogether, and all they could show first in plans was the general principle. **Mr. May** asked if the line had been constructed in the manner shown? **Mr. Moore**: In a large number of places, yes.

Alderman Moon asked Mr. Volk who was responsible for advising the erection of the poles 80 yards apart. **Mr. Volk** replied that he was responsible for the position of the poles, but as he had not had experience in putting up poles he referred the matter to Mr. Dawson, the company's consulting electrical engineer. Mr. Dawson had put up many miles of trolley line, and he assured him that the wire could be safely worked with the poles 80 yards apart. **Alderman Moon** next questioned Mr. Dawson as to the possibility of adopting the Westinghouse system, which is in use at Washington, and in which the wires are underground. **Mr. Dawson** held that it would be impossible to adapt it to a case where the cars were running over water.

Mr. Wright, replying to a question addressed to him by Councillor Stafford, said he thought the use of a gas motor would be the cheapest solution of the present difficulty. It could be worked much more cheaply than an electric motor, and, according to Prof. Kennedy, the vibration produced would not be noticeable. Nor did he consider there was any danger from explosion; while in connection with the gas-motor in use elsewhere on tramcars, there was an arrangement for starting, reversing, slowing, and for increasing speed in going up hill, and he saw no difficulty in applying that system on the largest scale necessary for the purposes of this railway.

After further discussion, the **Town Clerk** reported the resolution as a recommendation from the committee of the Council as follows: "That the application of the Brighton and Rottingdean Seashore Electric Tramway Company, dated September 23, 1895, for permission to erect 13 tubular steel poles 80 yards apart on the foreshore between Paston-place jetty and the borough boundary at Black Rock, for the purpose of carrying the electric trolley line be, and is hereby, granted, provided that the company pay a rental of £1 per annum and enter into a bond for £1,000, with two approved sureties, to remove the poles within three months after the receipt of a notice to that effect from the Corporation, and also to remove the rails and concrete blocks in the event of the line being abandoned, or not worked for a period of six months."

This resolution was carried unanimously.

THE PACIFIC CABLE.

The beginning of the end in regard to this proposed cable seems to have arrived. A private deputation of Colonial representatives conferred with Mr. Chamberlain on this subject at the Colonial Office on Tuesday, and Mr. Chamberlain's views have been made public. He is reported to have observed that such a meeting of the council of the Empire, brought together for the purposes of common interest, and attended by representatives of the Cape and Natal, which were not concerned with the project in its present form, was an evidence of solidity and sympathy. He expressed his opinion that the project showed a very fair prospect of remunerative return on the capital required, and his willingness to join in the formation of a joint commission, which should report upon the subject. He suggested that a commission should be formed, consisting of two representatives of Great Britain, two of Australasia, and two of Canada. After some discussion, it was arranged that the Colonial representatives should be named by the Colonial Governments and appointed by the Imperial Government, and that the commission should consider and report upon the subject in all its aspects. It was also arranged that the Agents-General and the High Commissioner of Canada would move their Governments to appoint representatives on this understanding.

The *Chronicle*, in a leader on Wednesday, commenting on this interview, among other things, says: "The scheme has been in the air for more than ten years. It took definite shape at the Ottawa Conference last year, and the fact that it yesterday received the approval of so many of the Australasian Governments is proof of the need at the Antipodes of this second telegraphic line to England. Even the Cape and Natal sent their Agents-General to yesterday's conference, for they look forward to the day when branch lines from the main cable may open up new telegraphic routes for them. It was, then, in the words of Mr. Chamberlain, a meeting of the council of the Empire for purposes of common interest, and the Colonial Secretary made it at once clear that the scheme would have the full co-operation of the Imperial Government in view of the great commercial and strategic advantages arising from an alternative and all-British cable line to the Antipodes. Primarily, of course, the cable is a question of cost. It was estimated at the Ottawa Conference that it would take two millions sterling to lay a single cable from Vancouver to Australia, and the figures put before the conference suggested that under a joint Government guarantee of interest the undertaking would in a few years become self-supporting."

Referring to the work of the commission, the *Chronicle* continues: "Two alternatives will be brought before that commission. The construction and working of the cable may be handed over to a company under some form of Government guarantee, or it may be undertaken by the Imperial and Colonial Governments and worked as a joint State undertaking, as our inland telegraphs are. The weight of Colonial opinion favours a State system, but the position of the existing lines under Sir John Pender's control would then have to be considered. All this,

Digitized by Google

however, the commission will weigh. The material fact for the moment is that Mr. Chamberlain has pledged the Imperial Government to co-operate with the Colonial Governments in the undertaking."

Our opinion has long since been freely expressed, and is in favour of such a cable. Still, there are one or two points we should like to refer to at the present juncture. As the *Chronicle* puts it, the existing cable route to the East is practically controlled by Sir J. Pender. The lines so controlled have been constructed and carried on with a view to absolute monopoly. The game of playing men against men in order to retain this monopoly, of getting the ear of the Press, of pitting nation against nation, has been skilfully played; we will say nothing of the conscientious methods pursued, for they are too often conspicuous by their absence. Far better had these monopolists understood the march of progress, then their opposition to the inevitable would have been tempered with reason. They have long argued that lines with infrequent stations could never pay; that in case of war the short lines could be more easily defended, and, if injured, more easily repaired; that, if necessary, short splices could more easily be made to shut out of circuit any given port; and that competition would ruin both parties. They have never put forward the fact that to accomplish their ends they have completed a system in which many vital points would be in the hands of enemies in the case of war. When compelled to admit this or that point would be so, they contend alternative routes would be open, forgetting that these alternative routes have also points in the hands of possible enemies. If any dispassionate and unbiassed observer will take a map of the world and try to find a means by which England could communicate with the various Colonies in the time of war without foreign supervision, we think that that observer will come to the conclusion we have expressed. Sir John Pender is great upon the millennium being brought about by the aid of cables, and that the linkages by cable must bring about the friendship of nations. This is unmitigated nonsense. The sole consideration is self-interest. If it pays men to believe this twaddle, they will do so. The importance of the Pacific cable is that it forms a link in the cable system which will enable England to communicate with her Eastern Colonies without the line of communication anywhere touching hostile territory. From our point of view, the proposed line should be absolutely independent of the existing system, and we hope to see the day when Australia will be connected direct to London by a system of lines that shall be under the control of Englishmen only. The existing Atlantic lines from this country are not of this class. Pooling has made them common property. It is to the interest of England and her Colonies in these days, when Imperial interests are becoming more and more important, to be what we might term self-contained. We trust, then, that the favourable views of Mr. Chamberlain will lead to action in the near future. He, as a business man, goes straight to the point of the capital expended being remunerative, and if convinced in this direction, the sooner the work is undertaken the better.

HIGH AND LOW PRESSURE.

Whatever may be the opinion of individual engineers as to the merits of the new regulations proposed by the Board of Trade, it must be universally admitted that the rules have not been passed without open discussion. The revised regulations and the amendments proposed to them by the various engineers and corporations interested have been most carefully gone through in the conference held at the Westminster Town Hall this week. The discussion is reported fully in our columns. We propose to leave the summary of the concessions gained until next week. The definition of terms which preceded the regulations, and which form the subject of this leader, gave rise to a most important discussion. The Board of Trade proposed that all pressures over 300 volts with direct currents, and 150 volts with alternating currents, should be considered as high pressures and treated as such. The real point at issue, however, hinged on the fact that a subsequent rule stated that all high-pressure mains should be insulated throughout. Therefore, if 200-volt lamps were used on the three-wire system, the use of bare copper strip in culverts would be forbidden. The replacement of mains already constructed with bare copper would cause a very large outlay in many of our most important electric lighting undertakings. In consequence, the term "low pressure," as defined above, was strenuously opposed by all station engineers, and few supporters were to be found to prove that pressures over 300 volts in private houses would be dangerous. We fully agree that with ordinary precautions there is no danger from using 500 volts between the extreme wires of three or five-way systems. From the amendment as eventually adopted for the consideration of the Board of Trade, it seems likely that the 300-volt limit will be adopted in a form which prohibits this pressure being exceeded between any conductor earthed or between any two adjacent wires of the three and five wire system. This will allow of a 600-volt difference of pressure between the outside conductors, and will also permit of the use of high-voltage lamps.

THE REVISED REGULATIONS OF THE BOARD OF TRADE.

A largely-attended meeting of representatives of municipal corporations, electric lighting companies, electrical engineers, and others interested was held at the Westminster Town Hall on Tuesday, under the presidency of Sir Courtenay Boyle, K.C.B., to consider the draft of the revised regulations of the Board of Trade in reference to electric lighting. The chairman was supported on his right by Major P. Cardew, R.E., the electrical adviser to the Board of Trade, and on his left by Mr. W. H. Preece, C.B.

In opening the proceedings, the CHAIRMAN said the Board of Trade had found it necessary to revise the regulations made under the Electric Lighting Acts of 1882 and 1888, and they had thought it convenient and desirable to give everyone who had raised any objections to the revised regulations an opportunity of stating what those objections were and of supporting them by verbal argument. The Board, he thought, had been amply justified in taking that course by the large and influential assembly that had come together. The responsibility of issuing regulations was devolved upon the Board of Trade by statute, and the Board could not divest themselves of it, but before issuing the new regulations they would carefully weigh every argument or any point which might be brought before them. With reference to the representatives of some of the telephone interests whom he saw were present, it might be well to say that the telephone interests would not be affected in any way by the regulations they were about to consider.

We give below the draft revised regulations, which also appeared in our issue of June 7, and append to each section the written amendments sent in to the Board of Trade for that section. These amendments are followed by the speeches of the gentlemen supporting them and the replies of the chairman and Major Cardew to the points raised. *Note.*—The regulations are give in larger type than the amendments, speeches, etc., which follow them.

Mr. C. Hammond enquired if the new regulations would be retrospective, and was informed that each clause would be considered by itself as to whether it should apply to work already carried out.

ELECTRIC LIGHTING ACTS, 1882 AND 1888.

DRAFT REVISED REGULATIONS.

Definitions.

In the following regulations—

The expression "the order" means the ——— order.

The expression "the undertakers" means the undertakers for the purpose of the order.

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals.

The expression "aerial line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; pressure on any alternating-current system being taken to be the equivalent of pressure on a continuous-current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament; and (*a*) where the conditions of the supply are such that the pressure cannot at any time exceed 300 volts, if continuous, or the equivalent of 150 volts, if alternating, the supply shall be deemed a low-pressure supply. (*b*) Where the conditions of the supply are such that the pressure may exceed the limits of a low-pressure supply, but cannot exceed 3,000 volts, or the equivalent of 3,000 volts, whether continuous or alternating, the supply shall be deemed a high pressure supply. (*c*) Where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts, or the equivalent of 3,000 volts, the supply shall be deemed an extra high-pressure supply.

Mains, service lines, and other conductors and apparatus are referred to as low-pressure, high-pressure, and extra high-pressure mains, etc, according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the Order or principal Act have the same respective meanings in these regulations.

AMENDMENTS.

Definition—"Pressure" (*a*) in conjunction with Regulation 1.

British Insulated Wire Co.—Apparently prohibits taking of an alternating service into a building on the three-wire system at 200 volts between the outer conductors. Point out that the danger of shock to the person is the same where a two or three wire service is used from a three-wire network, which is apparently not prohibited.

Notting Hill Co.—300 volts should be increased to 600 volts.

Dover Co. and County of London Co.—That the pressure should be raised to 440 volts for continuous current, and 220 volts for alternating current.

Hanley Corporation.—200 volts should be substituted for 150 volts alternating in order that the three-wire system may be used for low-pressure mains. The idea that alternating current is more dangerous than continuous to the extent presumed in the regulations is a mistaken one.

Institution of Electrical Engineers.—Wording of definition of pressure between two conductors to be amended to make matters clearer (no amendment suggested). Wording to be made clear that with three-wire system 200 to 250 volt lamps may be allowed. Voltage should be raised to 600 volts continuous, and equivalent of 500 volts if alternating. Support general desire of the profession to use glow and incandescent lamps taking from 200 to 250 volts at their terminals.

London Chamber of Commerce—The clause should be amended so as to define its application to three-wire and other multiple systems.

Manchester Corporation.—The omission of the following proviso, which was contained in the old regulations, makes their system a high-pressure system In order to comply with the requirements for high pressure, the Corporation would have to remodel the whole of generating station, and relay greater part of conductors. Moreover, Board of Trade have approved of their system as a low-pressure supply. "Provided that in the case of conductors laid under the surface of the ground in conduits, in accordance with these regulations, and being the property or under the sole charge of the undertakers, 'low-pressure conductor' shall mean any conductor in which the pressure between that conductor and the earth cannot at any time, if continuous, exceed 300 volts, or if alternating, 150 volts, or between that conductor and any other conductor laid in the same conduit cannot at any time, if continuous, exceed 500 volts, or if alternating, 250 volts." If the proviso is omitted, suggest that clause (*a*) be altered to read "where the conditions of supply are such that the pressure cannot at any time exceed 500 volts (? 450) if continuous . . . the supply shall be deemed a low-pressure supply." Urge that Manchester be exempted from operation of new regulations so far as the system (a five-wire system) is concerned (hitherto defined as a low-pressure system), or that the definition of high pressure and low pressure may be so modified as to continue Manchester as a low-pressure supply, to apply to all future extensions of the five-wire system in Manchester. Offer evidence.

Glasgow Corporation.—Definition of low pressure to be raised, so that at the least 200-volt lamps may be used.

Northern Society of Electrical Engineers.—To read, "Where the conditions of supply are such that the pressure cannot at any time exceed 500 volts, the supply shall be deemed a low-pressure supply."

Definition.—Pressure (*a*), (*b*), (*c*), in conjunction with Regulation 1.

London Chamber of Commerce.—The voltage should be raised to 500, and no distinction should be made between alternating and continuous current systems.

On behalf of the British Insulated Wire Company, Limited, **Mr. Nesbitt** supported the amendment given above, and stated that the regulations would condemn many systems now at work.

Mr. R. E. Crompton, who throughout represented the Institution of Electrical Engineers, which has considered these regulations in committee, said that the recent improvements in the manufacture of incandescent lamps had resulted in reliable lamps being produced to work at pressures of from 200 to 220 volts. On the three-wire system this would mean a pressure of 440 volts between the outside wires. This was one of the most marked improvements of the last four years, and everyone was anxious to make use of the advantages to be derived from the higher pressure. The Council of the Institution considered that 600 volts was a safe pressure, and therefore it should be allowed. He would point out that the Board of Trade had allowed 500 volts to be used for systems of electric traction, and he considered the dangers incident to a lighting system were less than from a traction system at the same pressure. He had had experience of the shock from 600 volts, and he did not consider it would permanently injure a man in good health. He knew that there had been a few cases of death resulting from a shock at lower pressures, but he considered that the united experience of the world showed that these cases were due to weak heart. The majority of electrical engineers held that 600 volts was a safe pressure, and the adoption of that limit would greatly simplify the systems of distribution and be of enormous benefit to the electrical industry.

Mr. Musgrave Heaphy, speaking on behalf of the Phœnix Fire Office, stated that he would much prefer the 300 volt limit should remain in the regulations.

Mr. Alexander Siemens, arguing on the ground that experience had so perfected the manufacture of boilers that high steam

Digitized by Google

pressures could be used with safety which would have been formerly quite impossible, said that he considered a higher limit for electric pressure quite safe. He mentioned an instance in which a workman had taken a shock from an alternating-current supply at 2,000 volts for half a minute without receiving permanent injury. It depended on the condition of the subject whether a shock would be fatal or not. In view of the progress of the electrical industry, he advocated making the limit higher than in the old regulations.

Prof. A. B. W. Kennedy remarked that there were a great many undertakers who had deliberately adopted the three-wire system at 200 volts, with the distinct knowledge that in five or ten years they would be able to use lamps of 200 volts or higher pressure, and that gave a pressure of 400 to 450 volts between the outside wires, or, say 500 volts at the terminals of the dynamo. These systems had been adopted in the knowledge that it would be advantageous later on to use high-voltage lamps when it became possible to get them, and he must say he agreed with Mr. Crompton that the higher limit was quite a reasonable one He believed that in the future they would have 300 volt lamps, though at present he had not seen any, and he therefore hoped that the Board of Trade would give them the very highest limit consistent with safety. That would tend to economy of distribution, and therefore would cheapen the light, and be for the advantage of the public.

Dr. John Hopkinson referred to Manchester as a place where the troubles due to a higher pressure would have been noticed. They used there the five-wire system, with 450 volts between the two extreme wires. They had spent £175 000 up to last March, and now had almost expended the £100,000 obtained as an extra since then. They had had no trouble; they had set no buildings on fire; they had hurt no one; and they had given full satisfaction to consumers. They had at Manchester 937 consumers wired and they had never had a single complaint of a shock causing anyone inconvenience. They had thus been working advantageously with a pressure at the terminals of 450 volts, and he considered that was good evidence in favour of an extension of the limit up to something like 500 volts. They had worked the system with very great success financially, and there was no town in which there was such a large percentage of profit shown as was done at Manchester. They wanted to give the public the electric light cheaply, and it would certainly be exceedingly hard to interfere with Manchester doing what they had done hitherto with marked success.

The **Chairman** doubted whether the present system at Manchester would comply even with the present rules.

Mr. E. Manville said that he did not approve of the difference between the limits of pressure laid down by the Board of Trade for alternating and direct currents respectively. He did not consider alternating currents more dangerous than continuous currents, and would like the limit of pressure to be the same in each case.

Alderman Higginbottom, the chairman of the Manchester Electric Lighting Committee, pointed out that they had 89 miles of bare copper mains already laid, which would have to be reconstructed with insulated cable unless the limit of pressure was raised.

Earl Russell, who represented the London County Council, said that that body would not approve of a pressure of 450 volts being introduced into buildings. He would like to suggest that there should be in the regulations some intermediate class between low pressure at 300 volts and high pressure at 3,000 volts. That was a considerable jump to make at once

Prof. Ayrton said it was not clear what was meant by the term "difference of electrical potential between any two conductors through which a supply of electric energy is given" It was a question whether this referred to any two conductors in a house or in the system of mains. Assuming that it meant that 300 volts would be allowed between two conductors in one house and 300 volts between the conductors in the next house, it would give 600 volts between the mains in the culvert. If then, the middle wire was earthed, the maximum shock which could be obtained in the house would be one of 300 volts

Mr. Morse, who appeared on behalf of the Chamber of Commerce, thought that the clause should be amended so as to define its application to three-wire and other multiple systems He proposed that after the word earth the following should be inserted: "or between any adjacent wires of the three or four wire system."

Mr. J S. Raworth was of opinion that the limit should be raised to about 500 volts, and that the alternating current should be put upon something like an equality with the continuous current He had had great experience of high-tension work in Hastings, where 1,800 volts were introduced into the houses without any accidents occurring.

Mr. Sayers, of Bournemouth, advocated the raising of the limit for alternating currents above 150 volts. When there was a scattered district with houses standing in their own grounds a three-wire system was much better for the service mains, as the heavy wires required for the two-wire supply were exceedingly costly. He thought that 220 volts alternating between the extreme wires taken into the houses would be quite safe. As regards fire risk, the alternating current was less dangerous than the direct because the arc gave less heat.

Major-General Webber thought that the question of a safe pressure might be deferred, and that it should be submitted to a committee of experts.

Mr. Holder, the chairman of the Electric Lighting Committee at Hull, referred to the fact that they were expecting to use electric traction on their tramways. The limiting tension allowed on the tramways being 500 volts, it would be a great advantage to be able to work the light and power with the same machinery. He referred to the recent improvements in high-voltage incandescent lamps, and stated that Mr. Gibbons, their late electrical engineer, had succeeded in obtaining 8-c.p lamps to work commercially on 200-volt circuits.

Mr. J. Hesketh of Blackpool, said that his experience with the tramway there, which was worked at 250 volts, showed that there was no danger at that pressure.

Prof. Ayrton said he was prepared to accept Mr. Morse's amendment.

Major Cardew said that the question of what was to be considered high pressure depended upon other considerations than that of danger to human life. He did not say that in selecting 300 volts for a continuous current they had not arrived at a limit which might very fairly be the discriminating point between a pressure which might be dangerous and a pressure which might be taken with impunity. Many people could take a shock from more than 300 volts It all depended on the state of the skin, and no regulations could provide people with skins The regulations provided that low-pressure conductors need not be continuously insulated in the streets. Now they knew that there were certain dangers of corroding pipes, and the possibility of explosions and fires, and if they increased the pressure they must increase the risk of incurring these dangers. With the exception of Manchester, he thought the direct-supply systems had not been very free from these dangers on the whole. There had been regrettable accidents. The one at St. Pancras must be in the mind of everyone. At Southampton there had been an explosion, also on the St. James's and Pall Mall, on the Preston system, and on several others. Mr. Crompton had stated that in certain cases 500 volts had been allowed for traction purposes. But he could not agree with Mr Crompton that this was more dangerous in the street than in houses. Up to the present all the speakers had dealt with the subject from the point of view of the suppliers. No one had represented that the consumers were anxious to have 200 volt lamps, even if they were supplied gratis. All the advantages from the use of these lamps were on the side of the supplier. The only accident in the Board's experience in the British isles which throws light on the desirable limit was the late lamentable accident at Portrush The pressure there could not have exceeded 320 volts. The man was thrown upon the track and remained in contact with the rail for some considerable time. The doctors' evidence at the enquiry showed that in their opinion if the electrical shock had not been added to the mechanical shock, the man would not have succumbed. There had also been numerous instances of deaths of horses and cattle at a pressure of 300 volts.

Mr. Alexander Siemens, who had been a member of the committee of enquiry into the St. Pancras explosion, did not agree with Major Cardew in assuming that the trouble would be augmented with the increase of pressure He believed that the electrolytic action would have occurred just as much if only 50 volts had been used.

In summing up the matter, the **Chairman** said that the Board of Trade would carefully consider the suggestions and amendments He personally was of opinion that the limit could be slightly raised both for alternating and direct currents.

(1) Save as hereinafter provided, the supply of energy delivered to the consumer's terminals shall be a low-pressure supply.

(2) A high-pressure supply shall not be delivered to any consumer's terminals, except for special purposes, and with the approval of the Board of Trade on the joint application of the consumer and the undertakers, and subject to such further regulations as the Board of Trade may from time to time prescribe. But a high-pressure supply may be given to distributing or converting stations or to transforming apparatus on a consumer's premises in accordance with the following regulations.

Southport Corporation.—For "except for special purposes, and with the approval, etc," read "except for experimental purposes without the approval, etc."

The **Representative** of the Southport Corporation moved that for "except for special purposes, and with the approval, etc.," read "except for experimental purposes without the approval, etc.," and the **Chairman** said the Board of Trade would consider the amendment.

(3) An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

(4) No high-pressure electric line shall be used for the transmission of more than 200,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.

Bournemouth Co.—200,000 watts is too low, and at 2 000 volts pressure is under the economical size of conductor. Suggests 300,000 watts.

British Insulated Wire Co.—If the maximum size of cable were put at 300,000 watts, it would much more generally accord with practice, as many stations have ·15 cables in use to a large extent.

Dublin Corporation.—The term "line" should be defined. Does

Digitized by Google

it mean "cable"? If so, it should be stated, so that when a larger supply is needed it can be given by duplicating the cables.

Halifax Corporation.—Presume term "electric line" includes feeding and distributing mains, aerial wires, service lines, and house wires.

Dover and County of London Co.—Instead of maximum of 200,000 watts for an underground line, the current should be limited so as not to exceed 150 amperes for high pressure, which for 2,000 volts, with a variation of 10 per cent. in pressure, would give 375,000 watts as the limit. The effect of the clause as drawn would be to increase the number of mains in a district in which there is a heavy demand for current, and so to increase the difficulties as to insulation If the object of the clause is to make it correspond with old regulation (3) think companies would have no objection to provide duplicate mains where the energy would on any one circuit exceed 200,000 watts.

St. James and Pall Mall Co.—Limit of 200 000 watts on a high-pressure line is too low—*e.g.*, a proper and convenient section for such a cable on 1,000-volt continuous-current transmission would be 0·5 square inch cross-section of conductor. It is understood that such a main would consist of two or more cables to ensure continuity of supply in the event of injury to any one cable.

Southport Corporation.—Contend for use of high pressure concentric cables capable of carrying a current of 400,000 watts, and a cable having a sectional area of ·2.

Wolverhampton Corporation.—"Electric line" is not defined. Limit of 200,000 watts is unnecessarily low.

Hanley Corporation.—Limit of 200,000 watts is too low. The Corporation give instances where in their own system the limit would be inconvenient. They also refer to the inconvenience in the case of electric traction.

Institution of Electrical Engineers.—For 200,000 substitute 500,000.

London Chamber of Commerce.—The limit of 200,000 watts should be increased.

Chelsea Co.—The limit of 200,000 watts is too low. Suggest 400,000.

Charing Cross and Strand Co.—The limit of energy on any high-pressure line might be raised to 500,000 watts. This would admit ·50in. conductors on 1,000 volts or ·250in. on 200 volts. The multiplication of separate conductors on trunk lines is to be avoided as far as possible.

Portsmouth Corporation and Shoreditch Vestry.—In the case of a high-tension system (2,000 volts) limit provided in the case of an underground electric line would soon be reached. Conductors may be ¼in. section, and might with economy be used for transmission of more energy than that stipulated.

Manchester Corporation.—Alter to read: "No high-pressure electric line shall be used for the transmission of more than 330,000 watts, or in the case of an aerial line 50,000 watts except with the consent in writing of the Board of Trade, and unless such excess is of short duration, and is necessary for the maintenance of supply." Should their system be declared a high-pressure system (see remarks on definitions), and Clause 4 be enforced, they would not be able to fully employ the feeders already laid, or to work their engines and dynamos at full load.

Northern Society of Electrical Engineers.—Omit entirely.

Mr. H. M. Sayers, of Bournemouth, considered the 200 000-watt limit too low, as at 2,000 volts it was under the economical size of conductor. He would suggest that it be raised to 300 kilowatts.

Mr. Crompton moved the amendment proposed by the Institution of Electrical Engineers, that the limit be raised to 500 kilowatts, and said that there was no trouble in providing efficient automatic cut-outs.

The **Chairman** said he was willing to accept the alteration to 300 kilowatts, and suggested that the matter should be allowed to adjust itself commercially under the Board of Trade jurisdiction, as the clause allowed of special cases being considered separately.

Lord Russell hoped that the extension of the maximum would be limited to cases where concentric cables were used.

Major Cardew said that the danger was as follows: If there was an electric line conveying some 300 h.p. or 400 h.p., and a fault occurred at one point of the line, there might be a sudden development of heat equivalent to that horse-power at the point where the fault occurred. Under those circumstances something was bound to happen, and the possible effects were exemplified by the Cannon-street accident. In the Sloane-square explosion the sudden development of heat was sufficient without any gas being present to cause an enormous expansion of the air in a confined space, which lifted up the cover of the street box and threw it several feet away. He thought the proposed limit was reasonable.

The **Chairman** said that the matter would be carefully considered, but he did not think that the maximum could be safely raised to 500 kilowatts.

(5) Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.

British Insulated Wire Co.—That some directions should be inserted for the guidance of undertakers using a system in which the outer conductor is connected to earth. Quote cases in which, on such a system, a fuse has been used on each conductor, and, owing to weakness of the fuses or an overload, the fuse on the outer has gone, and the outer conductor of the cables and transformers or machine has been charged up to the full working potential above that of the earth, with consequent damage to the insulation.

Dublin Corporation.—Assume that a safety fuse will meet the regulation. That the clause as it stands is very vague.

Sheffield Co.—The outer conductor being earthed, conclude that the provision of an automatic cut-off refers to the inner conductor only.

Manchester Corporation.—Omit entirely. The sudden cutting off of a main, causing extinction of all lights connected to it, is to be avoided. The excess current might be due to a fault which would disappear in a few seconds if the mains were not disconnected.

Mr. Nesbitt, of the British Insulated Wire Company, thought that some directions should be inserted for the guidance of undertakers using a system in which the outer conductor was connected to earth. He knew of cases in which, on such a system, a fuse had been used on each conductor, and, owing to weakness of the fuses or an overload, the fuse on the outer had gone, and the outer conductor of the cables and transformers or machine had been charged up to the full working potential above that of the earth, with consequent damage to the insulation.

The **Chairman** said that the case would be met by having no fuse on the outer conductor.

Dr. John Hopkinson said that under the old regulations they were required to use fuses in the Manchester network. He had designed and provided fuses for this system, but had not ventured to put them in for fear of extinction of the lights. He proposed that the regulation should be omitted.

Prof. Kennedy said if a 200-volt lamp made a high-pressure system of the present three-wire arrangement the clause would seriously handicap the industry, as the fuses were decidedly not wanted.

(6) In every case where any transforming apparatus is used to convert a high-pressure supply into a low-pressure supply, some suitable automatic and quick-acting means shall be provided to protect the low-pressure system from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

Bournemouth Co.—Question whether such automatic means are really needed when earth-shielded transformers and earthed metallic shielding between H.T. and L.T. conductors are everywhere employed.

Sheffield Co.—Assume that the provision of transformers which are completely enclosed in metal cases with an iron screen between the primary and secondary windings connected to earth meets the requirements of this regulation.

Southport Corporation.—Presume proper fuses are referred to.

London Chamber of Commerce.—In the absence of any known suitable device of the kind described the clause should be omitted.

Phœnix Fire Office (Transformers).—"It may be of interest to you to know that since the use of the Cardew safety device not a single instance of the high-pressure current getting into the low-pressure system in any building insured with this company has come before us."

Manchester Corporation.—Omit entirely. With a pressure of 400 volts it is unnecessary.

(7) The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30deg. F.; and efficient automatic means shall be provided which will render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time; and special care shall be taken that the cross-sectional area and conductivity at joints are sufficient to avoid local heating, and that the joints are protected against corrosion.

British Insulated Wire Co —Assume that in future fuses on the low-tension network will be a necessity.

St. James's and Pall Mall Co.—The meaning of the clause is not quite clear in reference to a low-pressure distribution, and the use of quick-acting automatic cut outs on a low-pressure network might be attended with serious results from an unnecessary stoppage of supply.

Institution of Electrical Engineers.—Omit "or in any case to raise such temperature to a greater extent that 30deg. F., and efficient automatic means shall be provided which will render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time."

London Chamber of Commerce —Should be omitted, as it is covered by Clause 5.

Phœnix Fire Office —It would be better to state a temperature above which a conductor should not be raised in the event of 50 per cent. above the maximum working current being sent through it.

Manchester Corporation—Omit "and an efficient automatic means shall be provided which shall render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent. even for short intervals of time." Consider the requirement prejudicial to the interests of consumers, as should there be a momentary increase of current from any cause, undertakers would be compelled to cut off supply, and put a portion, if not the whole, of their system in darkness. The result in the case of theatres, etc., might be disastrous.

Northern Society of Electrical Engineers.—Omit entirely.

Digitized by Google

Clauses 6 and 7 were discussed together.

Mr. Sayers, referring to the observation of the Bournemouth Company, pointed out the impossibility of any dangerous contact if the earthed metallic shield between the high and low pressure was adopted.

The **Chairman** said that the earthed shield was considered to be an automatic device under the clause.

Mr. Wright (Brighton) asked if earthing the middle wire would constitute an "automatic means."

The **Chairman**: I am advised not.

Dr. John Hopkinson, for Manchester, said the clause was an old one. In the large majority of low-tension stations it had not been carried out, because it was felt that they were far better without cut-outs. A law that was constantly transgressed with impunity was better revoked. He moved the omission of all from the word "efficient" down to the word "time."

The **Chairman** said he was advised that that could be done.

(8) The sectional area of the conductor in any electric line laid or erected in any street shall not be less than the area of a circle of one-tenth of an inch diameter, and when the conductor is formed of a strand of wires each separate wire shall be at least as large as No. 20 standard wire gauge.

Burnley Corporation.—Line 1, after "electric line" insert "hereafter." Submit that regulation should not apply to wires already laid down, which in some cases are of a less diameter than than that described.

Bolton Corporation.—They comply with the regulation except in the case of pilot wires; but as these wires do not convey energy to the public, perhaps the regulation does not apply. (Sample of wire enclosed.)

London County Council.—The regulation permits the use of wires in stranded conductors as small as No 20 standard wire gauge. Suggest that the smallest wire to be used shall not be less than No. 16, or in any case not less than No. 18.

Walsall Corporation.—It should be made clear that the regulation does not apply to pilot wires, or to wires used for telephonic purposes.

Cardiff Corporation.—Their arc light cables do not comply with this regulation. The strand of wires therein is composed of 47 wires. No. 23 standard wire gauge

Dover Co. and County of London Co —Suggest that wires in a strand should not be less than No. 18 standard wire gauge. Company limit size to No. 16, having found cables containing wires of No 20 gauge liable to break down in use.

Lancaster Corporation.—Suggest that regulation apply only to conductors hereafter laid, and that word "hereafter" be inserted after "electric line" Wires of diameter slightly less than that prescribed have been laid in Lancaster, and to replace them would cause much expense and inconvenience.

Blackburn Corporation —Pilot wires should be excepted

Hanley Corporation.—Suggest addition of words, "except with the consent in writing of the Board of Trade." This regulation will prevent the lighting of one, two, or three street lamps of 16 c p. each through a smaller cable than $^{7}/_{20}$ S.W.G. This is manifestly unnecessarily large. The requirement that each separate wire shall be at least as large as No. 20 S.W.G. will be found particularly inconvenient in the case of concentric cables. $^{7}/_{20}$ is unnecessarily large for pilot wires and pressure wires

Institution of Electrical Engineers.—Omit regulation and substitute, "Every cable or test wire laid or erected in any street must be of sufficient mechanical strength to enable it to be brought into position without injury."

London Chamber of Commerce.—Similar to observations made by Institution of Electrical Engineers above.

Charing Cross and Strand Co.—Pilot or pressure wires should be excepted.

Glasgow Corporation.—Pilot wires should be exempted from the operation of this clause. There is no practical necessity in making them as large as the minimum defined

Northern Society of Electrical Engineers —Add 'except pilot wires and in junction-boxes or other situations where extreme flexibility is necessary."

Eastbourne Co —Company have a considerable quantity of cable of less section than that specified, and substitution of another of larger scale would entail an uncalled-for expenditure. Where these cables are in use they are worked at a moderate current density, and are sufficiently large for the purpose required, such as for service mains into houses and for supplying a few houses in an outlying district.

The **Chairman** said that the amendment from Burnley might be accepted, thus making the clause prospective only.

(9) Every electric line shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each line or section of a line. No electric line shall be brought into use in which this test indicates an insulation resistance less than at the rate of 100,000 ohms per mile for every volt of pressure of the supply, unless it is connected with earth with the consent of the Board of Trade, in which case the insulation resistance of such electric line shall not be less than 10 megohms.

Bournemouth Co.—Where concentric cables are used, is the insulation of the outer conductor to conform to this regulation or only that of the inner conductor? 10 megohms. Is this to be the minimum insulation of the whole high-pressure system regardless of extent, or per mile of cable? If the former, the standard is higher than experience proves possible or necessary.

Burnley Corporation.—That low pressure service lines should not be included in the regulation, and that whenever the cable for service lines has been tested on the drum it should not be necessary to again test the separate lengths when cut off. The apparatus would be costly and cumbersome for street use

National Electric Supply Co.—The regulation as it stands would prevent the employment of bare copper systems, as in use at Preston, which work perfectly well in practice Their insulation does not reach the required figures, but the company have had no trouble therefrom

British Insulated Wire Co.—The 200 volt testing pressure is unusual, and will tend to upset present arrangements. The usual testing pressure is only 100 volts, batteries being arranged in sets for the purpose.

Halifax Corporation —The regulation is vague. Assuming that "electric line" includes a network, consisting of feeders, distributing main, service line, and house wires it would be practically impossible to obtain, with a testing pressure of 200 volts, so high an insulation resistance as that prescribed; or, assuming that "electric line" is a service line laid and about to be jointed to a network, a test of the service line alone would be of little practical use, as the fault, if any, would probably occur at the joint.

London County Council.—Some further definition seems to be required as to when, how, and by what means the tests are to be made, or all these matters might be left by the regulations to be approved in detail by the Board of Trade

Burton on-Trent Corporation —If "every electric line" is to include consumer's wires, such wires will be incapable of standing the proposed test. In the case of "service lines," is the test to be made after they are jointed to the low-pressure mains? If so, and the consumer's wires are excluded from the testing, it will be necessary to switch off all the consumers The whole of the low-pressure distributing mains and service lines on that section would then be tested and whether after or before the test, expense would be caused in providing a generator or battery, which will be very cumbersome to carry about. Corporation now use the ordinary "Silvertown set" for testing outside the works. Suggest that the voltage should be reduced and the words "electric lines" limited in their meaning to the undertakers' electric lines only.

Notting Hill Co.—Too severe. The minimum standard of 10 megohms can hardly be maintained; the more joints that are placed in a cable the lower will be the resistance to earth.

Yorkshire House-to-House Co.—It is not clear whether the insulation test proposed is intended to apply only to complete new circuits or is also to apply to additions to circuits. Company's pressure of supply being 2 000 volts, the minimum insulation resistance proposed to be required would be 200 megohms per mile, and they doubt whether it is practicable to obtain by means of portable apparatus such accuracy of testing as would be required in short lengths of main if the proposed regulation apply to such.

Ogmore Valley Co —Is 200 volts test necessary? Company's working pressure is 115 volts.

Lancaster Corporation.—Too stringent as regards low-pressure service wires and consumers' wires. To ensure that new consumers' wires should stand proposed test would seriously affect cost of private wiring and check adoption of the light. Apparatus required for proposed test would be costly to buy and cumbersome to use. Suggest that regulation shall not apply to low-pressure service lines not exceeding 20 yards in length, or to low-pressure consumers' wires and fittings.

Wolverhampton Corporation.—The testing E M F. of 100 volts in the old regulations is satisfactory, and no good purpose would be served by raising it to 200 volts.

Islington Vestry.—The wording of latter part of regulation is vague. If main is earthed, it obviously could not have an insulation resistance of 10 megohms.

Institution of Electrical Engineers.—Line 1, after "electr line" insert "except service lines" Line 5, before "electric line insert "high pressure." Line 7, for 100,000 ohms read 25 000. A end of regulation add "per mile before connecting to earth"

London Chamber of Commerce.—Same as Institution; also that clause is not clear.

Chelsea Co —A testing pressure of 200 volts is extremely inconvenient, an effective battery of such an E.M.F. not being sufficiently portable; 100 volts should be sufficient for continuous currents.

Glasgow Corporation.—Clause is exceedingly stringent. Quite impossible to lay bare copper strip and fulfil the conditions of insulation resistance imposed here. At best it could only be a laboratory test and, for working purposes, of no value. The maximum leakage allowed in next clause can very easily be complied with with a very much lower test for insulation.

Charing Cross and Strand Co.—The standard is too high for a line including several joints and connections. On a network including several thousand lamps connected this standard is impossible.

St. Pancras Vestry.—Figures given are far in excess of what may be got on a bare copper system of good design. For direct current and bare copper systems, the electrical osmosis speedily brings down the insulation to a low point on the negative.

Newcastle Co.—This could only be done before the line is brought into use. It would be well for Board of Trade to specify what they would consider suitable means for the immediate indication of faults of insulation.

Portsmouth Corporation and Shoreditch Vestry.—Intention of latter part of regulation not clear. If system be connected to

Digitized by Google

"earth" it is impossible that there can be greater insulation resistance than that represented by the resistance of the conductor itself from its extreme end to point at which it is connected to earth. Neither is it stated whether the "10 megohms insulation resistance" refers to the total length of a circuit, or if not, to what length. A long circuit with a number of large street-box transformers would involve difficulties in maintaining an insulation resistance inclusive of the transformers of 10 megohms per mile.

Westminster Co..Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation —That the condition is a prohibitive one Although condition forms part of old regulations have not heard of any attempt to enforce it. Doubt if there is any system of mains in which the required insulation can be obtained without the warming up of end connections and the taking of other special means to bring up the insulation, which practically deprives the test of all real value.

Manchester Corporation.—Alter to read as follows: "Every electric line shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each line or section of a line. No electric line shall be brought into use in which this test indicates an insulation resistance of the insulating material exclusive of surface leakage less than at the rate of 100 000 ohms per mile for every volt of pressure of the supply, or (less than) at the rate of 1 000 ohms per mile for every volt of the pressure of the supply including surface leakage, unless it is connected with earth with the consent of the Board of Trade, in which case the insulation resistance of such electric line shall not be less than one-half the quantities above named." The high-insulation resistance *per se* is not essential to safety. The magnitude of the insulation resistance depends entirely upon the material used for insulating. If this material be indiarubber, a low-insulation test would show bad quality. If paper, the insulation might be much lower, and yet the cable be equally safe; and if bare copper be employed, the insulation resistance might only be $\frac{1}{100}$ of that of rubber-insulated cable, and yet the system would be as safe.

Northern Society of Electrical Engineers.—In line 1, after "line" insert "except service lines." Line 3, for "200" read "100." Omit paragraph commencing "No electric line" and ending with "megohms."

Mr. H. M. Sayers moved the Bournemouth amendment, and asked for a definition on the subject whether the 10 megohms applied to the whole system.

The **Chairman**: It applies to the whole system

Mr. Sayers said that meant a different standard for a small system than for a large one.

Major Cardew said the regulation only required that a test should be taken of new cables when they were put in, and it was intended to ensure that a high standard of cable was laid.

Mr. Sayers thought there should be a standard per mile, and suggested 50 megohms.

Mr. Hammond thought the point referred to by Major Cardew should be made clear by adding the words "before it is connected with the apparatus."

The **Chairman**: I will accept that

Lord Russell suggested some such expression as "length of wire or main"

The **Chairman**: I like Mr. Hammond's words.

Mr. Nesbitt thought it should be left to the engineer to decide whether he would lose the leakage in a mile of cable or in six inches of porcelain.

The **Chairman** said the Board would consider if it was not possible to reduce the 100,000 ohms per mile.

Mr. Crompton said the Institution of Electrical Engineers had moved to insert the words "high pressure," as otherwise the whole clause would apply to low-pressure systems, and it would be absolutely impossible to carry it out. The alterations proposed by the Institution would make the clause workable. The insulation of a complete low-pressure system might vary from two or three ohms to 200 ohms at the best On the other hand, if the clause only meant that they were to test the cables before they laid them, why did it not say so? To speak of lines made the matter very obscure, and it was a fallacious test at the best, for a man might buy a very good cable and lay it so badly that it would fail. If the Board wanted to ensure a cable was well laid, they should apply a working test. With bare copper laid in conduits, the proposed test and standard was prohibitive, although such mains gave no trouble in practice.

Major Cardew said that the test was intended to ensure that care should be taken in drawing in the cables, and to provide against cables being accepted from the maker's test, and not being tested after they had been handled. The test was to be made immediately the cables were laid and before connections were made to them

Prof. Kennedy said that in certain circumstances, however good the cable might be, it would require what was vulgarly called "faking" to pass the test; for instance, the uncovered ends would have to be warmed up. If, however, the regulation referred to bare copper he would say that he had used many miles of it, and had had no trouble whatever from it, but at no time would it be possible to get on it any insulation resistance like the figure proposed—not even on the driest days. Yet he had never had any case where the limit of insulation came below the working limit His point was that there were many systems carried out with the consent of the Board of Trade which could not fulfil Clause 9, but which could easily fulfil Clause 10. The first was an old clause that had never been fulfilled so far as bare copper strip was concerned.

The **Chairman** said what was wanted was that when a cable was laid there should be some test. If they could help the Board to get that, he was prepared to meet the views expressed.

Prof. Ayrton asked if the clause applied to short service lines.

The **Chairman** said it did not. He would suggest an alteration reducing the 100,000 ohms to 25,000 ohms, and a provision that the regulation did not apply to short service lengths, say, of 20 yards.

A **Representative** from Liverpool said on their system, with bare copper mains and a few sections of cable, they could not get the insulation required by the clause.

Mr. Baynes said that the insulation required could not be obtained under any circumstances with the bare copper system. He would advocate rather a separate clause to deal with the bare copper system, and proposed that it should be based on a minimum insulation for each point of support

The **Chairman** then announced that he would advise the Board of Trade to amend and shorten the clause as follows: "Every electric line shall be tested for insulation after having been placed in position, and before apparatus is connected to it, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each line or section of a line."

(10) The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of or in connection with such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and localisation of faults of insulation. Every such fault shall be remedied without delay. Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of such testings. Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to such circuit so long as such connection exists.

Bournemouth Co.—Submit that on low-tension mains tests at much longer intervals than a week are sufficient. To maintain the insulation at the standard mentioned may involve much interference with consumers' installations, over which the undertakers have no effective power, especially if the low figure of 5,000 ohms is retained in Clause 45 Question how leakage current is to be distinguished from displacement or capacity current, in alternating current systems. A few miles of high-pressure mains give a capacity current measurable in amperes with the frequencies in general use.

Burnley Corporation.—State that, so far as their knowledge goes, it is impossible to provide apparatus for the immediate localisation of faults of insulation; also that it is impracticable to test the leakage current of low-distributing mains without disconnecting the consumers. Submit that regulations should provide that circuits may be tested for insulation by testing the leakage current to earth.

National Electric Supply Co—Should be modified so that where undertakers have an apparatus showing any variations in the insulation, a weekly test should not be required unless some fairly simple method is devised whereby the test can be taken without stopping the supply.

Dundee Gas Commissioners —Consider leakage current allowed is too small.

Notting Hill Co.—Regulation too severe.

Dover Electricity Co. and County of London Co —Inapplicable to an alternating-current system, since the condenser current on long lines is much more than the minimum specified, and is practically undistinguishable from leakage current.

St. James and Pall Mall Co—Clause does not say how the leakage current is to be ascertained; it is presumably by earthing either conductor and noting amount of current passing. Ask if such an earth connection is to be allowed. Eut in conjunction with Clause 45, undertakers might be compelled to make supply to any consumer having an insulation resistance above 5,000 ohms. If such an insulation resistance become at all general, the leakage current from this source alone would greatly exceed that allowed by Clause (10). Ask if undertakers have authority to insist on an insulation resistance in excess of 5,000 ohms.

Southport Corporation.—Paragraph 2: for "one week" read "two weeks."

Ogmore Valley Co.—Weekly tests unnecessarily frequent.

Lancaster Corporation.—Provisions are impracticable If a network of low-pressure mains is one "complete circuit," it is impossible to provide suitable means for the immediate indication and localisation of faults of insulation. If such a network consists of a number of complete circuits, each of which has to be tested once a week, a serious expense will be involved, and continual interruptions of the supply will be necessary. Suggest reconsideration of regulation, especially as regards its application to low-pressure distributing mains.

Blackburn Corporation.—Second paragraph. This is impossible on the low-tension system, and would necessitate disconnecting every consumer from the distributors one a week.

Wolverhampton Corporation.—Do not see how this can be applied to low-tension mains, as the leaks on consumers' premises are, together, usually considerable, and cannot be separated from the mains in practice.

Digitized by Google

Institution of Electrical Engineers.—Paragraph 1: omit all words after "circuit" in line 4. Paragraph 2: omit, "Every such circuit," and for "at least once in every week" read "from time to time."

London Chamber of Commerce.—"Leakage current" should be better defined, and in lines 9 and 10 "from time to time" should be substituted for "at least once a week."

Chelsea Co.—No instrument obtainable which would ensure immediate localisation of faults.

St. Pancras Vestry.—Same remarks as made on regulation No. 9.

Newcastle Co.—Insulation tests to be taken once in every week. This is always a cause of complaint with consumers, who find it inconvenient to be cut off every week.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—The clause is so out of proportion to Clause 9 as to be inconsistent with it. In case of Westminster, Clause 9 would compel every main to test up to 20 megohms per mile after being laid and before being connected, while under Clause 10 the insulation of the whole distributing mains the next day and when actually at work might only be about 200 ohms per mile. Meaning of Clause 9 appears to be clear, and "leakage current" appears to mean actual leakage current while the mains are in their ordinary working condition, and not the current which can pass to earth when, say, the positive is momentarily earthed for the purposes of testing. The wording of the regulation might be made clearer.

Manchester Corporation.—Alter to read: "The insulation of every complete high-pressure circuit used for the supply of energy including all machinery, apparatus, and devices forming part of, or in connection with, such circuit shall be so maintained that the leakage current shall not, under any conditions, exceed one-thousandth part of the maximum supply current, and in the case of low pressure the insulation of the whole system, including the installations of consumers, and all machinery, apparatus, and devices shall be so maintained that it shall not fall below 1,200 megohms, divided by the number of watts in the maximum supply. Every fault shall be remedied without delay, and the undertakers shall keep a daily record of the insulation resistance. Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to this circuit so long as such connection exists." As the clause stands at present, it is not clear whether the test is to include the installations of consumers. If it is, the standard set up is much higher than could be attained if Clause 45 stands, as in the case of 1,000 consumers, each of whose installations is just above the minimum, the joint insulation resistance would only be five ohms, which would be the insulation of the circuit were the mains absolutely perfect. If the test is not to include the installations of consumers, it is absolutely impracticable to carry it out, since it would involve the disconnection of each consumer from the mains. In the case of large stations with, say, 1,000 consumers connected, there would not be time to test them, and the public inconvenience caused would preclude the use of the light.

Northern Society of Electrical Engineers.—Leave out all after "such circuit" in lines 3-4 of first paragraph down to "shall" in line 1 of second paragraph. In place of "at least once in every week" insert "from time to time." Omit last paragraph commencing "Provided" and ending with "exists."

Mr. H. M. Sayers, in moving the Bournemouth amendment, emphasised the difficulty of distinguishing between the capacity current and leakage current when alternating currents were employed.

Prof. Ayrton pointed out that this difficulty did not exist, as the difference in phase between these two currents provided a ready means of determining their respective values by the aid of a wattmeter.

Mr. Barker, of Cambridge, said that the test could not be applied where a large number of transformers—say, 150—would have to be disconnected from the system.

Mr. Crompton stated that he considered this obligation to test the mains once a week unnecessarily severe, and moved that words "from time to time," or "at frequent intervals" be inserted. In certain cases daily tests were not too frequent, but, on the other hand, sometimes a test once in three months was ample.

Major Cardew said that the idea of the Board of Trade was to encourage some continuous system of testing, and recording the insulation of the system with respect to earth.

Mr. Crompton said that the insulation at successive instants varied enormously, as certain bad circuits were switched on, which thus prevented the continuous test from indicating the condition of the mains.

The **Chairman** said they wished the test to include the leakage on the consumer's premises.

Mr. Crompton said it would be impossible to localise the fault without detaching the house circuit. A company had to take great precautions when sending their men into houses, and great objections would be raised to frequent visits.

Prof. Kennedy thought a company should not be responsible for anything beyond their own mains.

Major Cardew said the supplying company must be looked to to see that the insulation was maintained on the consumer's premises, as the company was empowered to disconnect when there was a bad leak on the wiring, and they were also empowered not to connect if they considered the work on the consumer's premises was unsatisfactory. In the case of a bad fault they could cut the consumer out at once, and the Board therefore left it to them to keep the insulation of the whole circuit up to a reasonable amount. He thought experience showed that there would not be many very bad cases.

The **Town Clerk of Bournemouth** said he was directed to ask the Board to take reasonable precautions for the public safety.

Mr. Gay, of Islington, said he had known cases where contractors had refused to make alterations required on the ground that they were within the limit the Board of Trade prescribed as a minimum.

The meeting adjourned for half an hour, and on resuming the **Chairman** said he would accept the suggestion that "once a week" should be omitted. At present he had no definite amendment before him.

Major-General Webber said the word circuit, which was a telegraphic one, should be defined.

Dr. John Hopkinson suggested one two-hundreth part of the maximum current should be the limit, but he would be content with such a limit as would bring them into agreement with Clause 45.

Mr. Morse observed that the undertakers had no power to enter private houses except they contained apparatus which was the undertaker's property.

The **Chairman** said it would not be necessary.

Prof. Kennedy said he had found it to be necessary in some cases.

Major Cardew said the test should be applied to the parts of the wires in the house belonging to the undertakers.

Prof. Kennedy: You must disconnect yourselves.

Major Cardew: Yes.

Prof. Kennedy then referred to the difficulty of disconnecting the supply mains if a vulcanised joint was used.

Major-General Webber proposed an amendment that the test should be such a one as was approved by the Board of Trade, as this would allow for the difference of systems in use.

Lord Russell concurred, as it was not desirable that too low a test should be adopted generally in order to cover the needs of some special system.

Mr. Gunnion, who appeared with Lord Russell for the London County Council, thought it would be only putting off the evil day, since each company would be left to fight with the Board of Trade as to what were the particular requirements of its system. They must not omit to take care of the public safety through a desire not to be hard on a particular company. If one wanted one safeguard removed, and another another safeguard, by the time all were satisfied they would be left without any safeguards at all.

Mr. Preece said the clause was a most important one. There was not a single electrical enterprise that had not been kept in order by some such means as were desired by the clause. Major-General Webber had suggested that the clause was liable to be misconstrued, and that it did not include the lamps and apparatus in houses. In his (Mr. Preece's) mind it included everything. Serious trouble had arisen from the way in which cheap work was put into houses, and also from the fact that the maintenance of the work was often neglected entirely. On the other point, that once a week was too frequent, he thought that there was nowhere a much larger electric system to be kept in order than the telegraphic and telephonic system of the Post Office of this country, and the practice there was to test all the circuits every morning. It was done with the greatest ease, and gave them the earliest possible notice of any faults. He could not imagine that any electrical enterprise could find any real difficulty in securing a test once a week. As a practical man, he would urge that the clause should be maintained. The test of one one-thousandth part was not a large one. It might be necessary to make a reduction in some cases, but that should be the exception and not the rule.

The **Chairman** said he could not announce any decision on the subject that day. The **Chairman** said that There was an obvious misprint in the next two clauses. The last sentence in Clause 12, commencing with "If this protection . . . ," should come at the end of Clause 11.

(11) All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.

Burton-on-Trent Corporation.—Submit that last sentence of Regulation 12 should be transposed to this regulation.

Notting Hill Co.—Regulation too severe.

Institution of Electrical Engineers.—Transpose last sentence of Regulation 12 to end of this regulation; but alter the sentence by inserting the words "except in the case of low-pressure lines" before "be efficiently."

London Chamber of Commerce and Charing Cross and Strand Co.—Add last sentence of Regulation 12 at end of this regulation.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—"This protection" appears to refer to insulating material, which obviously cannot be intended.

(12) Every high-pressure conductor shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000. If this protection be wholly or partly metallic, it shall be efficiently connected with earth.

Bournemouth Supply Co.—Point out omission of words after "20,000" relating to "protection" as distinguished from "insulating material."

Digitized by Google

British Insulated Wire Co.—A provision should be inserted making it compulsory that the metallic protection shall be continuous throughout its length, and should be put to earth at one spot only.

London County Council—Some words have evidently been dropped out in the last line but two.

Burton-on-Trent Corporation—If regulation will apply to existing high-pressure wires, Corporation will have to remove all their high-pressure conductors (which are $^{7}/_{16}$'s) and all the electric lines between them and the transformers Suggest that clause should not apply to existing high-pressure conductors belonging to works already provided. Can specify minimum insulation of one-tenth of an inch for all future extensions. Submit that last sentence of clause should be struck out and added to Clause (11).

Yorkshire House-to-House Co.—Minimum thickness of one-tenth of an inch of insulating material is in the case of small cables unnecessary, and that the quality of the insulating material should be taken into account as well as the thickness. Are advised that for smaller sizes (up to $^{7}/_{14}$) one-tenth of an inch is too great a thickness, but that the thickness should vary in proportion to the size of the cable. Their cable in use has a guaranteed minimum insulation of not less than 5,000 megohms per mile at 60deg. F.; suggest that a test of this character would be of greater value than mere thickness of material without regard to quality.

Wolverhampton Corporation.—Is this intended to apply to armoured concentric cable?

London Chamber of Commerce—For the smaller size of cable one-tenth of inch insulating material is too great a thickness. Thickness should vary with the size of cable.

Manchester Corporation.—Omit entirely. If the clause is enforced, nearly the whole of their existing feeders will have to be relaid.

Eastbourne Co.—Minimum insulation resistance specified is excessive for small conductors. A large proportion of company's cable has a less thickness of dielectric, but it is of the best quality vulcanised rubber, and is further protected with insulating tape, etc.

Institution of Electrical Engineers.—See observations on Regulation 11.

Clauses 11 and 12 were taken together. It was suggested that if the limit of pressure were not raised the Manchester bare copper mains would come under the regulation, hence their motion to omit the clause, and the **Town Clerk of Hull** said the same thing applied to their case. With the good system of ventilation adopted, bare copper had been used at Hull with perfect success for three years.

Mr. Crompton said that he could see no object to be gained in earthing a protecting metallic shield with the direct-current low-tension system.

Major Cardew said it was most undesirable to have a conductor in a conduit which was insulated and not connected to earth. Not being a part of the circuit, its potential was indeterminable.

Mr. Crompton protested against this. It was simply an experiment.

Lord Russell supported the regulation.

Mr. Urquhart said if it was an experiment it was one that had been tried for a considerable period with success at Richmond, where the metallic protection of the cables was connected to the iron culverts.

Mr. Hammond, on behalf of the Yorkshire House-to-House Company, urged that the regulation should not be retrospective. They had many conductors laid which would not conform to the minimum thickness clause and yet would give over 5,000 megohms per mile.

Prof. Kennedy remarked that this was one of the clauses affected by what would be the decision as to raising the limit for low pressure. It would decide whether Belfast, Edinburgh, Richmond, Glasgow, Dundee, and Oldham came under the regulation.

Mr. H. W. Wilkinson, of Eastbourne, said they had some bare copper mains there which had given no trouble over a period of 13 years, and which they did not want to relay.

The **Chairman** said he proposed to advise the Board that the regulation should be prospective only, but with this condition—namely, that if any evil effects were discovered from the want of conformity to this regulation, the company concerned would then have the regulation made applicable retrospectively.

(13) No electric line, machine, device, or apparatus intended to form part of, or be connected with, a high-pressure circuit shall be brought into use unless the insulation thereof has withstood the continuous application during one hour of twice the pressure to which it is intended to be subjected in use. The undertakers shall duly record the results of such test.

Bournemouth Co.—Qy. If this is to be applied to the outer insulation of a concentric cable what fraction of the working pressure between the two conductors is to be taken as the working pressure between the outer conductor and the earth. Point out that the outer conductor under normal conditions takes very nearly earth potential, but under occasional accidental circumstances may be exposed to the full working pressure.

Bolton Corporation.—If the regulation is retrospective, it would cause great inconvenience, and possibly breakdown, to test all their existing high-pressure plant with 4,000 volts for one hour.

Dublin Corporation.—The regulation will be difficult to enforce. Corporation test cables and transformers to 50 per cent., and doubt advisability of exceeding this. Think that it would not be safe to test generating plant at double working pressure.

House-to-House Electric Light Co.—Consider it would be running a great risk to double the voltage required in some instances, such as alternators.

London County Council.—The test to be applied should be made by some method and under conditions approved by the Board of Trade; or, alternatively, further definition should be inserted.

Burton-on-Trent Corporation.—Suggest elimination of clause as unnecessary. Their machines, etc., have not been tested to twice working pressure, and they would be put to considerable expense in providing special "step-up" transformers and other appliances for conducting the test

Wolverhampton Corporation.—Much too rigorous. Application of a test pressure or 50 per cent. above working pressure is ample.

Islington Vestry.—Object to include word "machine." Do not think it would be judicious to subject any alternator or dynamo to twice the working pressure.

Taunton Corporation.—Regulation should be relaxed in stringency; it is unnecessarily severe Their adviser suggests that all concentric cables intended for use with high-tension current should be tested with double the working pressure for one quarter of an hour, applied between the inner and outer conductor, and a pressure equal to the working pressure between the outer and earth, and that all alternators and transformers should be tested for half an hour with a pressure 50 per cent. greater than the working pressure.

London Chamber of Commerce.—The words "machine, device, or apparatus" in line 1 should be omitted.

Chelsea Co.—The provisions of this clause would be detrimental to the plant. If at all necessary, the full working pressure applied during 15 minutes should suffice.

Newcastle Co—Impracticable for a representative to see a test and record the result in connection with every piece of machinery supplied. Suggest that the guarantee of the manufacturer as to the testing should satisfy Board of Trade.

Portsmouth Corporation and Shoreditch Vestry.—Suggest subjecting apparatus to twice working pressure for a quarter of an hour, and to a 50 per cent. increase on the working pressure for a further three quarters of an hour.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—This would compel the testing of every dynamo or alternator for one hour to twice its working pressure: This is undesirable Probably this is not the intention of the clause.

Manchester Corporation.—Omit entirely. It would be very expensive and very troublesome to carry out this test, and quite unnecessary for so low a pressure as 400 volts.

Northern Society of Electrical Engineers.—Alter "twice" to "1½ times."

Institution of Electrical Engineers.—Line 1, omit "machine, device, or apparatus."

On this clause **Prof. Kennedy** asked if the test applied to alternators, as in that case he considered it too stringent.

Major Cardew thought it was too high a test for those machines.

Mr. Gay said it most serious to have a dynamo subjected to a double pressure. It might strain the insulation and cause a breakdown at some future date. He would suggest that 25 per cent. above normal pressure would be a better value to give as the increase.

Mr. Hammond suggested 50 per cent. It might happen in testing an alternator that the engine varied its speed, and cause the E.M.F. to rise to that value.

Mr. Gay asked if it was permissible to use a current from outside for testing, or must the machine be run at the pressure indicated.

Major Cardew said an outside current might be used.

Prof. Ayrton said there were certain cases where for a moment there might be a pressure very much exceeding the working pressure on an alternating system. In putting on a transformer there might be a pressure of 4,000 volts for the fraction of a second. The proposed regulation was therefore desirable.

The **Chairman** asked how a 25 per cent. increase of pressure for a machine and twice the pressure for a cable would meet the wishes of the meeting.

Lord Russell suggested rather a six hours' run at 50 per cent. excess for machines, as being in the interest of the public voltage.

Mr. Hammond said a six hours' run at full load never occurred in practice.

Mr. Crompton, on behalf of the Institution of Electrical Engineers, urged that the Board of Trade were considering the safety of the public, which was not at all concerned, as the machines were all in the generating station. He thought they should avoid grandmotherly legislation.

Lord Russell objected. If a machine broke down and earthed 2,000 volts, he presumed that would affect the mains.

The **Chairman** said there was pressure continually kept upon the Board of Trade to be more grandmotherly than it was.

Prof. Ayrton said the proposal amounted practically to a clause in the specification for the supply of the apparatus.

The **Chairman** asked how Prof. Ayrton got over Lord Russell's argument.

Prof. Ayrton said it was no argument at all.

The **Chairman** said his decision probably would be a test of twice the pressure for an electric line and 50 per cent. in case of a machine.

In this clause, the words "by fire, or explosion, or any accident," were struck out, and "have caused" altered into "cause."

(14) Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

(15) Where any accident by fire or explosion, or any accident causing or likely to have caused personal injury

Digitized by Google

occurs at any part of any electric line or work to which these regulations apply, the undertakers shall give immediate notice thereof to the Board of Trade.

Burnley Corporation.—That the regulation should be revised so as to provide that only accidents causing or likely to cause personal injury should be reported. Suppose Board of Trade do not require to be informed of every trivial accident that occurs at the station or elsewhere.

Lancaster Corporation.—Clause covers every trivial accident Suggest revision so as to provide that only accidents causing or likely to cause personal injury be reported.

Blackburn Corporation.—The wording is too general, and might include any petty mishap.

Wolverhampton Corporation.—Do not think there should be any necessity to report accidents which have caused no serious personal injury.

Institution of Electrical Engineers.—Line 1, after "where any" insert "serious," lines 1 and 2, omit "or any accident."

London Chamber of Commerce.—Line 4, after word "apply" insert "except on the consumer's premises."

Glasgow Corporation.—Clause is vexatious. Only such accidents as have actually caused personal injury, that would necessitate the removal of the injured person from his work for a number of hours, should be reported.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—Wording of clause is so vague as to be inoperative except in most serious cases. It seems doubtful whether it is desirable that any such reports should be made to the Board of Trade except in serious cases.

Mr. Barnard moved the suggestion of the Lancaster Corporation. The regulation should only apply to serious accidents.

The **Chairman** said he had tried for years to define what was a "serious accident," and had failed.

Mr. Hesketh objected to "likely." A high-tension fuse blowing might cause injury, and were they to report that? He would propose only cases where a man had been injured so as to be kept from his work should be reported.

Mr. Hammond thought it would cause a very large number of reports.

The **Chairman** said in the case of the railways every man who jammed his thumb was reported to the Board.

Mr. F. Bayley asked if the regulation applied to accidents on the consumer's premises.

The **Chairman** said it would not, unless the premises were under the jurisdiction of the undertakers.

Mr. Sayers said they had already to give notice of injuries to workmen under the Accidents to Workmen Act. It should not be necessary to give two notices of the same thing.

Mr. Boveridge (Edinburgh) proposed to alter the wording to "where any accident causing serious personal injury."

The **Chairman** said "no." An explosion might happen to cause no injury and yet be exceedingly serious. The regulation practically repeated what was in the provisional orders, and would stand with the exception of the alterations above.

(To be continued.)

LEGAL INTELLIGENCE.

ELECTRIC LIGHT CLAIMS.

Proof was recently led in the Sheriff Court at Linlithgow in an action at the instance of Messrs. Hunter and Jack, electrical engineers, of Glasgow, against Mr. Henry S Kirsopp, draper, of Bathgate, for payment of £36. 4s. 7d., being the balance of contract price for an electric light installation to the defender's premises in Bathgate. The contract price was £166 6s. 8d. The defender had paid part of this to account, reducing the amount to the sum sued for. Defender contended that the pursuers asked permission to fit up on the outside of his premises two arc lamps for the inauguration of the installation. Defender averred that the lamps did not turn out satisfactory; that in the month of January last one of the brackets from which the lamps were suspended broke, and in its fall smashed one of the defender's shop windows, and injured two women and a child. He attributed the accident to carelessness in fitting up the lamps, and said that the bracket was insufficient to bear the strain of the lamp. Defender also stated that he had paid the persons who were injured £30 in full of their claims for damages, and he held that pursuers were bound to repay him that sum, as well as to allow him certain deductions, and that there were due to him more than the amount sued for. The Sheriff has now issued an interlocutor in which he finds that pursuers having completed the work they are entitled to payment of the sum sued for. The lamps, he says, which were at first fitted up, were changed for two lamps of a different pattern; one was removed and placed in a higher position by the defender without the sanction of the pursuers, and the defender ought either to have left the arc lamp in the position in which it was at first placed or called in the pursuers to remove it.

In the Westminster County Court on Friday the case of Harrison *v.* Estelle was tried before his Honour Judge Lumley Smith, Q.C., and was a claim by the plaintiff, an electrical engineer, to recover a balance of account of 15 guineas in respect of electrical work done to the order of the defendant.

It appeared from the opening statement of counsel that the plaintiff had done work to the extent of over £100, the greater portion of which had been duly paid for, but the defendant appeared to have adopted the opinion that the work now claimed for was in respect of alterations which had been rendered necessary owing to the plaintiff's own mistake in the fixing.

The **Plaintiff** was called and gave detailed evidence as to the items which were the subject of this action, and absolutely denied that the work was rendered necessary owing to his own mistake.

The **Defendant** was called and said that in several respects the work was not carried out according to her orders, and consequently she had to request the plaintiff to make some alterations, but she never expected to have to pay extra for that.

His **Honour**, having gone through the whole of the items at some length, said he thought the defendant was right as to some of them, therefore he should reduce the plaintiff's claim by six guineas, and give judgment for nine guineas and costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—The Corporation invite tenders by 10 a.m. on December 2 for the supply and erection complete of two dynamos at the Foreign Animals Wharf, Mode Wheel. Full particulars are given in our advertisement columns.

Magdeburg.—The State Railways invite tenders by November 26 for the supply of 25,800 kilos of galvanised iron wire and 1,500 porcelain insulators on screw supports. Conditions for 1 mark from and tenders to Die Königl. Eisenbahn-Direction, Magdeburg.

London, S.W.—The Secretary of State for India is prepared to to receive tenders for caissons, air-compressing, and electric light plant. Particulars are to be obtained from the Director-General of Stores, at the India Office, S.W., and tenders must be delivered by December 10.

Leicester.—The Corporation invite tenders for the supply and delivery of the necessary cast-iron pipes and connections, from 2in. to 24in. in diameter, required during 12 months ending December 31, 1896, for the Gas and Electric Lighting Committee. Specification and form of tender to be obtained from Mr. Alfred Colson, M.I.C.E., engineer and manager, Millstone-lane, Leicester. Tenders, addressed to Alderman Lennard, chairman, and endorsed "Tender for Cast-Iron Pipes, etc.," are to be delivered by 11 a.m. on December 7.

Brussels.—The Ministère de la Guerre invitee tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.—The Administration des Télégraphes requires tenders by December 18 for the supply of various large lots of pine telegraph poles. Special cahier des charges No. 26 at the Brussels Bourse.—The municipal authorities invite tenders by November 26 for the supply of pipes and apparatus in connection with the electricity works. Security 5 per cent. of the amount of the tender. Conditions from L'Hôtel de Ville, Brussels.

Swansea.—The Corporation invite tenders for the following works: Contract No. 1: For the supply and erection of destructor and electricity supply station buildings complete, including engine and destructor houses, offices, approach roads, and yards. Contract No. 2: For the erection of a chimney shaft, 150ft. in height, with all necessary foundations and accessories. Contract No. 3: For the supply and erection of a dust destructor, including eight destructor furnaces, and four water-tube boilers, with all flues, dampers, and accessories necessary to the satisfactory setting to work of the same. Specifications, bills of quantities, and forms of tender of the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, S.W., for £3. 3s. each specification. The plans can also be seen at the offices of the engineers or at the Guildhall, Swansea. Sealed tenders are to be sent to Mr. Jno. Thomas, town clerk Guildhall, Swansea, endorsed "Swansea Dust Destructors and Electricity Supply—Tender for Contract No. 1, 2, or 3," as the case may be, at or before 4 p.m. on December 6.

RESULTS OF TENDERS.

Brompton (London).—The following tenders were received for electric light wiring and fittings, for the committee of the Cancer Hospital, Brompton, S.W. Mr. Morgan Williams, A.M.I.C.E., was the consulting engineer:

	Wiring.	Cutting away and making good.	Fittings, exclusive of lamps.
Crompton and Co.	£668 0 0 ...	£45 0 0 ...	£107 8 0
Rashleigh Phipps and Co. ...	523 0 0 ...	20 0 0 ...	115 5 6
H. M. Leaf	330 0 0 ...	25 0 0 ...	99 11 6
Drake and Gorham (accepted).....	309 0 0 ...	25 0 0 ...	86 19 0
Sotheby and Co....	293 10 0 ...	26 10 0 ...	77 14 0

Bursiem.—The tender of Messrs. Crompton and Co., Limited, amounting to £213, has been accepted for supplying and fitting an electric light installation in the baths.

Tongres.—For the electric lighting of Tongres. Tenderers: Compagnie Internationale d'Electricité, Liège, 0·308f. per hour per arc lamp of 8 amperes, and 0·0385f. per hour per 16-c.p. incandescent lamp; Société anonyme d'electricité (Bouckaert et Cie.), Brussels, 0·308f. ditto, and 0·029f. ditto. The Société anonyme

Digitized by Google

du phœnix and the Société pour les applications générales de d'electricité (systèmes Siemens et Halske) Brussels, also tendered.

Saltash.—The Town Council have accepted the tender of Mr. T. Martyn for lighting the public lamps by electricity at an annual cost of £2 10s. per lamp, subject to a guarantee for the discharge of the contract.

BUSINESS NOTES.

Aberdeen.—The Town Council propose to municipalise the tramway system. Electric traction is projected.

Cardiff.—A correspondence is taking place in the local Press as to the advisability of introducing electric traction on the tramways in Cardiff.

Woking.—The Urban District Council have resolved that tenders be obtained for lighting St John's Ward by electric light, gas, and oil.

Liverpool.—Prince's-road Calvinistic Methodist Chapel, Liverpool, is said to be the only Welsh chapel in the kingdom fitted with the electric light.

Llanelly.—It is likely that the Llanelly Borough Council will sell their provisional order for lighting the town by electricity to Messrs. J. C. Howell, Limited.

Hammersmith (London).—The Hammersmith Vestry have completed the purchase of a site in Fulham Palace-road, at a cost of £2,200, as a site for an electric lighting station.

City of London Electric Lighting Company, Limited.—A private meeting of this Company was held at Winchester House, E.C., on Monday last, the Press not being admitted.

The Eastern and South African Telegraph Company, Limited, announce the numbers of 5 per cent. mortgage debentures drawn for payment at par on January 1, 1896.

Hospital and Church Lighting.—Messrs. Drake and Gorham have been entrusted with the contracts for the electric lighting of the Cancer Hospital at Brompton and St. Paul's Church, Deptford.

Richmond (Surrey).—The Electric Lighting Committee of the Town Council have reported that the company had made the necessary deposit, and the authorised works were proceeding satisfactorily.

St. James's and Pall Mall Electric Light Company, Limited. We are informed that the recent issue of 4 per cent. debenture stock, offered to the shareholders at 2½ per cent. premium, was largely over-subscribed.

Colwyn Bay.—The District Council have discussed the question of electric *versus* gas lighting, and eventually it was agreed to hold a committee of the whole Council to come to a decision on the subject in a fortnight.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended November 17 amounted to £1,028, as compared with £881 in the corresponding week of last year, being an increase of £147.

British Electric Traction (Pioneer) Company.—The allotment letters for this Company's recent issue of 5,000 shares have been posted. We understand that the applications were largely in excess of the capital required.

Shoreditch (London).—The Shoreditch Vestry are about to enter into negotiations with the trustees of the Christian Institute, Hoxton, which abuts on the site for the electric lighting station, for the purchase of the freehold of the site.

Morecambe.—In the course of a discussion in the District Council on the price of gas, a member said that he did not think the present was an opportune time to see the gas company, because the Council had under consideration the purchase of the electric light works.

"Electricity."—Mr. Sidney Rentell, the proprietor of this popular-priced journal, informs us that owing to the constant increase in its sale, as well as of the technical works published by him he has had to remove to more commodious offices on the first floor of 11, Ludgate-hill, London, E.C.

Plymouth.—Mr. Radford has moved in the Town Council that an electric lighting committee be formed. Hitherto, he said, the question of electric lighting had been left in the hands of a small sub-committee, but so important a matter should be entrusted to a special committee. The motion was carried.

Rochdale.—Councillor R Howarth has asked if the committee appointed some time ago to consider the question of electric lighting had met yet? The Chairman said the committee had met. It was thought possible that they might make some arrangement with Messrs. Platt to get power from their coke ovens.

Newcastle-on-Tyne.—The Corporation intend to apply to Parliament in the ensuing session for leave to bring in a Bill for the improvement of the tramways system now in use. Powers are to be sought to double certain existing lines, which, along with the new lines, are to be worked by "animal, steam, oil, mechanical, cable, or other powers."

Shepshed (Leics.).—The Ratepayers' Association have sent another communication to the Urban Council, in which they recommend the Council to consider the rapid progress the electric light was making before deciding to purchase the gasworks in the present defective state of their mains.

Horseless Car Company, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares. Object: to acquire any patents and inventions relating to motors or motor carriages, and to develop and turn to account the same, and to act as engineers and machinists generally. Registered office, Trafalgar-buildings, Northumberland-avenue, W.C.

Birmingham.—The first meeting of the Nechells Overhead Electric Traction Committee has been held at the Lister Hotel, Great Lister-street; Mr. Newton presiding. It was resolved to write to the Central Tramways Company for information as to the proposed system, and the honorary secretary was instructed to submit their reply to the next meeting of the committee.

Edinburgh.—In view of the Chrysanthemum Show, Waverley Market has been fitted with the electric light. The contractors for the wiring of the market were Messrs Milne and Sons, and the Corporation supplied the lamps. The cost of the installation is between £600 and £700. The Town Council have agreed to extend the electric lighting from the Post Office to Regent's-terrace.

City and South London Railway.—The returns for the week ended November 17 were £958, compared with £972 for the corresponding period of 1894, being a decrease of £14. The total receipts for the half-year 1895 are £17,616, compared with £17,691 for the corresponding period of 1894, being a decrease of £75. The line was partly closed last Sunday for alterations at King William street Station.

York.—At a meeting of the Streets and Buildings Committee of the City Council, Mr. Alderman Agar was elected chairman for the coming year A letter was read from Prof. Kennedy, stating the terms on which he would act as adviser to the committee in regard to the question of electric lighting for the city, and it was decided to employ Prof. Kennedy, subject to the settlement of certain matters of detail with him.

Electric Heating and Cooking.—We have received a copy of the new edition of the illustrated price list of the electrical heating and cooking apparatus manufactured by Messrs. Crompton and Co., Limited, of 35, Queen Victoria-street, London, E C., and Chelmsford. Messrs. Crompton are said to be the only company in the world who have received five diplomas and four gold medals (including Antwerp, 1894) for cooking and heating by electricity.

Belfast.—In addition to the other improvements which the directors of the Belfast Banking Company, Limited, have recently effected in their principal establishment in Waring-street, they have now introduced the electric light. The satisfactory character of the installation is extremely creditable to Mr. J. H. Greenhill, by whom it has been carried out. The illumination is supplied by four arc lamps of 3 000 c.p. each and 92 16-c.p incandescent lamps.

Dover.—Councillor G. Fry has moved that steps be taken to apply for a provisional order for the construction of tramways in Dover without binding themselves to any particular kind of motor. He proposed that the order should enumerate a large number of streets, so that if they desired they should be able to approach the pier, Buckland, and the Folkestone-road by several alternatives, and also Liverpool-street. The motion was adopted by the Town Council.

Brisbane Tramways Company, Limited.—This Company has been registered with a capital of £200,000 in £5 shares. Object: to adopt and carry into effect an agreement expressed to be made between the Metropolitan Tramway and Investment Company, Limited, of the one part, and this Company of the other part; to construct, project, hire, purchase, take, on lease or otherwise, equip, work, and extend, maintain and use tramways and light railways.

Derby.—The Chairman of the Electric Lighting Committee (Mr. Alderman Leech), in presenting the committee's report, has declared that there was no loss on the light, but a slight profit, and that the prospects of the business are exceedingly good. Mr. Leech proceeded to attack another member (Mr. Hart) for making a statement to the effect that a large sum of money had been needlessly spent. This statement, Mr. Leech declared, was quite incorrect.

Eccles (Manchester).—The Town Council have been called upon to consider "the deferred proceedings of the Town Hall, Tramways, and Electric Lighting Committee of September 23 and October 1, and if deemed advisable to order that the corporate seal be affixed to a contract with respect to electric lighting works, and to authorise application to the Local Government Board for borrowing powers." The further consideration of the subject was again postponed.

Godalming.—The Town Council have passed the following resolution: "That the Town Council of the borough of Godalming, acting as the urban sanitary authority, do apply to the Board of Trade, under the provisions of the Electric Lighting Acts, 1882 and 1888 for a provisional order authorising such authority to supply the electric light for public and private purposes within the area of the said borough, and also within certain parts of the parish of Godalming Rural."

The Telephone in Java.—The Intercommunal Telephoon Maatschappy is the name of a company which has lately been formed at Batavia, Java, with a capital of 500,000fl., to acquire and work concessions which have been granted for the establishment of telephonic communication between Batavia, Semarang, and Soerabaya, and between Batavia, Cheribon, Tegal, Pekalongan, and Semarang. A domand has further been made for a concession to erect and operate a telephone exchange in the town of Macassar, in the island of Celebes.

Forthcoming Bills.—The parliamentary advertisements have been made for Bills to be introduced next session by the Edinburgh Corporation for making, acquiring, working, or leasing tramways;

Digitized by Google

by the Corporation of Cork to produce, store, and supply electricity in the city of Cork; by a company to construct an electrical tramway from Derby to Ashbourne, with running powers over a portions of the lines of the Derby Tramways Company, Limited; and by a company to construct an electric tramway (3ft. 6in. gauge) from Kidderminster to Stourport.

Fareham (Hants).—A committee meeting of the whole of the members of the Urban District Council has been held to receive a deputation from a meeting held some time since, with a view to effecting a compromise of the action for non-fulfilment of contract for the purchase of the undertaking of the Fareham Electric Lighting Company. The views of the deputation as to an amicable settlement were lucidly explained, but they were not endorsed, it being decided to continue the action, the hearing of which is expected to take place within the next week.

Sheffield.—A body of British capitalists and tramway experts, called the London and Provincial Tramway Company Syndicate, are about to deposit a Bill in Parliament seeking powers to construct a complete network of electrical tramways in Sheffield. Their object is to take over from the Corporation of Sheffield all the lines of the existing system, to purchase from the company their freeholds and rolling-stock, and to provide a rapid regular, and prompt tram service which will bring all the districts within easy reach of one another. The overhead system is proposed.

Cowes.—A member of the District Council has submitted a proposition to the effect that the Cowes Gas Company should be asked for the lowest terms on which they would light the town with incandescent lamps. He urged that they should try to make some arrangement with the company before the Council went for the provisional order to use electricity. A long discussion ensued, in the course of which it was pointed out that the provisional order did not necessarily mean that the Council would themselves institute the electric light. The motion was lost, two only voting for it.

Bangor (Antrim).—At the last meeting of the Bangor Town Commissioners Mr. Bowman asked what steps had been taken by the Board relative to his motion regarding the electric light The Chairman said they had applied for the license The Clerk (Mr. Pollock) said that application had not yet been made Mr. Bowman said it seemed that it was necessary before applying for the license to give a month's notice, and that a special meeting should be called for the purpose It was decided to make the application in a formal manner by bringing it before a special meeting.

Miscellaneous Lighting.—Mr. George du Maurier has recently placed the electric lighting of his house in the Hyde Park district in the hands of Messrs. Rashleigh Phipps and Co, of 102 Oxford-street, W. This firm has also just completed the lighting of St John's Church, Paddington, where 200 lights have been installed. Messrs. Treloar's and Messrs. Hudson Bros.' central depôts in Ludgate-hill have just been lighted by this firm as also the Artists Volunteers' Headquarters, and they have carried out a large extension of the lighting of the St. James's Theatre, for Mr. George Alexander.

Halifax.—A scheme for laying down and working electric tramways in the Halifax district is about to be put forward by a syndicate of gentlemen interested in similar undertakings. Messrs. Land and Foster are the solicitors, and the preparation of the plans is in the hands of Messrs. Utley and Gray, surveyors and architects The line would extend from the bottom of Horton-street, *viâ* Wards End and Commercial-street, to Hall End, and thence by way of Silver-street and King Cross-street to King Cross and Sowerby Bridge Loop lines would probably be made to North Bridge, Highroad Well, and Salterhebble.

Neston (Cheshire).—A meeting of ratepayers of Neston and Parkgate has been held to consider the lighting of the district by electricity. Colonel Lloyd, who presided, said though they spent a 3d rate on gas, the district was not as well lighted as they would like to see it Mr. Grenfell described the economy of electricity, and said the report read at the last Council meeting was very encouraging, and whenever a municipality had undertaken the new departure it had been profitable in reducing the rates The expert he engaged said Neston could save by electricity £700 a year, and this would put the roads in order. Another meeting is to be called.

Nottingham.—A correspondent writes: "A novelty in the lighting of 'buses is about to be introduced into Nottingham by Mann's Nottingham Horse and Carriage Company, Limited, who are contemplating using electricity both inside and outside their 'buses. They have already built, for use to and from Bridgford, a model 'bus, which is fitted with the new lamps, and the vehicle has been very much admired. The lamps are fed from a battery under the driver's seat, and are capable of giving light for 36 hours The arrangements for charging the batteries being satisfactorily concluded with the Corporation, the lamps will be fitted in all the 'buses on the company's route."

Llandudno.—The engineer to the Llandudno District Council has presented a report on the question of providing Craigydon with telephonic communication in case of fire, and the superintendent of the fire brigade, in his report, recommended that telephonic calls should be fixed in the house of each fireman. The engineer was directed to write to four electrical engineers, asking for their terms for advising and reporting generally upon the whole question of the electric lighting of the town. Two applications had been received by the Works Committee for permission to lay down an electric tramway, but as a further application would shortly be received it was decided to leave the question in abeyance.

Douglas.—An arrangement has been entered into between the directors of the Derby Castle Company, Limited, and the directors of the Douglas Tramways Company for the sale of that portion of the Castle property the front line of which extends from the entrance-gates to the ornamental fountain just beyond the lodge. The price agreed upon exceeds £8 000. The property will be utilised by the tramways company for the building of the sheds necessary for the housing of their stock now that the present terminus buildings are to come down, and also for a handsome new station building, which will at once serve for both the Bay tramway and the Laxey electric tramway.

Windsor.—The Town Council have adopted the following report of the Electric Lighting Committee: "(1) A letter has been submitted to your committee from the Thames Conservancy stating that they cannot entertain the proposal to utilise the water power at Windsor Weir for the purposes of electrical energy. (2) Your committee report that they have given directions for an advertisement to be published asking for tenders for taking over the order for electric lighting, and recommend that if it shall appear that the piece of land in the Goswell's belonging to you is the most suitable site, that you sanction the use of a portion of that site for the purpose. Tenders are invited to come in by January 1, 1896."

Kidderminster.—The scheme for connecting Kidderminster and Stourport by an electric tramway is now taking definite shape, and notices have been given of an intended application to Parliament to incorporate a company for making such tramway. It is proposed that it should commence opposite the Town Hall buildings, Kidderminster, passing along Oxford-street, Bridge-street, and New-road, to Stourport, terminating at a point opposite the Bridge Inn, in Bridge-street, Stourport. A second line would commence at the intersection of Spirit-lane and Comberton-road, and connect in Oxford street with the line to Stourport. A third tramway is proposed, running westward of the line in the New-road. Messrs Ivens and Morton are the solicitors to the Bill.

The Archbutt-Deeley Water Purifying and Softening Process Practical and satisfactory demonstrations of this process were given the other day at Smedley, near Manchester, and Adlington, near Chorley. Two tanks, placed side by side, are generally used, the processes of filling, adding the chemicals (lime, alkali, and aluminoferric), and allowing the precipitate to settle being carried on in one, whilst the softened and clarified water is being drawn off from the other. Messrs Mather and Platt, of Salford, the manufacturers of the plant, state that it is at the present time being used, either for water softening or for effluent purifying purposes, by some 20 or 30 firms. The method is fully described and illustrated in the *Contract Journal* of November 20.

Allgemeine Elektrizitats-Gesellschaft, Berlin.—The report for 1894-95 of this Company is an elaborate document, and clearly demonstrates the prosperity of the concern. The number of employés has increased in the financial year from 3.385 to 5,121. The output has correspondingly developed, and 2.049 dynamos and electric motors, with a total capacity of 22,800,000 watts (about 30,000 h.p.), were turned out. Like stabilite, the new mikanite has met with ready acceptance as a high-pressure insulating material. The business profits amount to 4 035,867 marks, against, in 1893-94, 3,205,981 marks, being an increase of 829,886 marks. A dividend of 11 per cent. is proposed, which will absorb 2,200,000 marks; 110,000 marks are distributed as bonuses to the employés and donations to the provident fund; and 67,318 marks are carried forward. Prospects continue good.

Bangor (N.W.)—The electric lighting question continues to be discussed with unabated vehemence in Bangor. At the last City Council meeting Dr. Rowland Jones, in pursuance of notice of motion, proposed the following resolution: "That the resolutions passed at special meetings of the Council held on August 30, October 9 and 25, 1895, to carry out a scheme of electric light next year, to apply to the Board of Trade for a license, etc., and instructing Mr. Medhurst to proceed with the plans at once, etc., respectively, be rescinded, and that, in accordance with the tenour and terms of the resolution passed by the Electric Lighting Committee on September 20 last, and confirmed by the Council on October 9 next following, the Council do now apply to the Board of Trade for a provisional order only." After a long debate Dr. Rowland Jones's resolution was declared lost by 13 votes to 8.

Telephones in the West Riding.—The Duke of Norfolk has received a deputation from the West Riding on the subject of increased facilities for telephonic communication being granted to Yorkshire. The Duke of Norfolk eventually said there were two points to be considered—one the unification of the area in question, and the other the increase of the trunk wires. As to the first point made if acceded to it would upset a scheme maturely considered, and he would only be misleading them if he held out any hope of being able to do that. The areas were all specified and had been drawn up carefully, and the deputation asked that they should all be thrown into one. This could not be done. As to the second point, about the increase of trunk wires, they were anxious to do all they could in that direction to meet their wishes. Perhaps they would like to send in writing any suggestions as to special cases

Ashton-under-Lyne.—Councillor Kelsall said, at the last Town Council meeting, that they ought to appoint an electric lighting committee Previous committees had to all intents and purposes been stillborn. If they had a committee, they would not have the semi-scandal of retaining powers for carrying out the electric lighting scheme and doing nothing to accomplish the purpose. Tradesmen were complaining and people were putting in private installations. He moved that a committee be appointed, and Councillor Phillips

Digitized by Google

seconded. The Town Clerk said it would be necessary, in appointing a new committee, to adopt instructions to it. Would it not be better to consider the matter in General Purposes Committee? The town clerk's suggestion was agreed to A number of formal resolution were then passed with regard to the application to the Local Government Board mentioned in the minutes of the General Purposes Committee.

Appointment Vacant.—The Governors of the Belfast District Lunatic Asylum will on December 9 appoint an engineer for Purdysburn auxiliary. Candidates must be over 20 and under 35 years of age, and the person selected will be required to devote all his time to the asylum service. He must be able to take charge of steam-engine and boilers and the electric lighting plant, and have previous experience in running private plant with batteries, and be able to do his own repairs. Applications with copies of testimonials respecting character and efficiency, and certified copy of registry of baptism, should be sent in by noon on December 7. Salary £65 per annum, with rations, residence, clothing, fuel, light, and washing.—The Lighting Committee of the Wolverhampton Corporation require a clerk and canvasser in the office of the borough electrical engineer. Particulars will be found in our advertisement columns.

Norwich.—A petition on behalf of the Property Owners' Association has been presented to the Norwich Town Council protesting against the exorbitant prices charged by the British Gaslight Company for gas, both for private and public consumption, and asking further that the Council should take steps for opposing the Bill of the company now before Parliament. A member thought the matter was of grave importance, and he moved that the memorial be referred to the Law Committee, with a request from the Council to take the most energetic steps in their power with a view to preventing the gas company extending their monopoly, and for the Council to avail itself of the opportunity to appear before the House of Commons, so that the citizens may obtain relief from the present exorbitant charges of the company for gas, etc. This was agreed to. Why does not Norwich try electricity?

Kettering.—A special meeting of the Urban Council has been called for the purpose of considering the expediency of applying for a provisional order authorising the Council to put down electric lighting plant in the town. The clerk read the minutes of the proceedings of the Electric Lighting Committee, which was a general decision to recommend the Council to apply forthwith to the Board of Trade for the necessary permission to supply electricity within a given area. The report of the committee was moved by Mr. F. Mobbs, who stated that the committee had gone carefully into the matter, and had been considering a list of 110 towns where the electric light was in vogue, and 112 others where it was contemplated. Personally, he was not in favour of the work starting at once, and if they obtained the order they would not be called upon to proceed with the work for two years. The motion was eventually carried.

Gloucester.—The town clerk has informed the City Council that in June last notice was received from Mr. Walter Webb, on behalf of the Great Western Light and Power Company, giving formal notice of their intention to apply to the Board of Trade for a provisional order authorising the supply of electricity for public and private purposes within the city. It had been resolved at a meeting of the Finance and Streets Committee to recommend the Council not to consent to the proposed application of the company but for the Council to apply for the provisional order themselves. The Mayor now moved that the Council should not consent to the application of the Great Western Electric Light and Power Company, and the motion was carried, as also a resolution that application be made to the Board of Trade for a provisional order under the Electric Lighting Acts of 1882 and 1888, to supply electricity for public and private purposes in the city.

Hampstead (London).—The Lighting Committee of Hampstead Vestry have reported that they had given instructions to the chief engineer to make a periodical report to them as to the loss of electric current in transmission, but were of opinion that such reports should not be presented to the Vestry, as no advantage could possibly arise by making them public. It was referred to the Lighting Committee to consider the advisability of extending the lighting cables from Heath-street to The Grove. Mr. Reed explained that by doing this now, when the cable was being laid in Heath-street, a considerable saving would be effected. The surveyor stated that his department and the Lighting Department work in conjunction when the cables are laid, so as to avoid unnecessary expense. Mr. Dainton complained that since the current had been switched on to the cables in West-End-lane his telephone had been rendered almost useless. There was a constant buzzing sound, which was due, he was told, to the electric lighting current. The engineer said that he had examined the telephone and found a constant buzzing. Telephones were greatly affected by the weather.

Bolton (Lancs.).—The *Bolton Journal* is publishing a series of articles entitled, "Shall Bolton Have Electric Trams?" The writer remarks that this is a question which will, without doubt, occupy the attention of the Corporation in the very near future A few months ago a sub-committee was appointed, consisting of equal numbers of the Street and Gas and Electricity Committees, to obtain information on the subject, and for the purpose, if necessary, of breaking down any prejudice which might exist in the minds of the public against the employment of electricity as a motive power in thoroughfares. The throes of a general election into which the country was plunged, followed by the local municipal contests, interfered with the active prosecution of enquiries into the subject; but the newly-constituted Corporation will now, in all probability, renew the consideration of the question as to the advisability of employing electricity instead of horse power in connection with the tramcars. By a clause in the agreement with Messrs. Holden, the lessees of the tramlines, electricity can be employed at any time should it be considered by the Corporation to be cheaper and more advisable than horse power.

Whitehaven.—Councillor Musgrave, in proposing the confirmation of the Water and Lighting Committee's minutes, said, with regard to the proposed extension of the electric light station, that he was very glad to say that their electric lighting had become so popular, and had been so much appreciated by the consumers, that they were getting a very satisfactory revenue from that source, and the probability of a very considerable increase in private consumption was so patent to the committee that they considered they should be looking round with a view to acquiring additional property to meet future demands. There was no immediate necessity for extension, but thought the time could not be far distant when some extension would require to be made Within the next few months the Council would be asked to sanction an application to the Local Government Board for further borrowing powers connected with the electric light.

Radcliffe (Lancs.).—Mr. Cunliffe, in accordance with notice of motion, has moved, "That this District Council, having obtained a provisional order for generating and supplying electricity for lighting and other purposes, take into consideration the advisability of putting this power into operation." He believed that Radcliffe of all places, ought to be lighted with electricity. The fact that they received a provisional order without opposition was favourable evidence as to the necessity of electricity in Radcliffe. The late Local Board went into the question of cost, and estimated that it would not cost more than £10,000, and he thought they might make an investment of £8,000. At the present time there were 603 lamps in the streets of Radcliffe and Stand-lane. The Council paid the gas company £389. 15s. 3d. for gas last year, and £171. 7s. 2d. were spent in wages to lamplighters, etc. That was a large sum, and a considerable amount of it might be saved if they had electricity. There were 35 localities in England where plants had been laid down, and £4,500,000 had been sunk. There were 25 towns where contracts had been let out for works, at a cost of £870,000, and 22 towns had obtained statutory orders for spending £822,000 The resolution was agreed to.

The New Electric Railways in London.—The City Commission of Sewers have had under consideration an application by the Central London and Waterloo and City Railway Companies to make certain modifications in the design of subways in connection with the central station to be constructed at the Mansion House. The modifications now suggested by Sir Benjamin Baker and the other engineers are principally to avoid interference with adjacent buildings One of the alterations is to connect the platforms of the Waterloo and City Railway by inclined subways with the system of foot-passenger subways to be formed in front of the Mansion House. Another modification has reference to the proposed staircase at the corner of Princes-street. Owing to the vaults of the Union Bank projecting further beneath the public way than was originally allowed for, the company desire to alter the plan of the staircase in such a way as to involve a further absorption of the carriageway. The Commission consider this alteration highly objectionable, and have refused their sanction to it In regard to the whole scheme, the Commission, before giving permission to commence any of the works, are requiring the Central London Railway Company to satisfy them as to their ability in every respect to complete the station, subways, and approaches in conformity with their Act. Communications between the Commission and the company on that subject are now being conducted with every probability of a satisfactory result.

Cambridge.—The Commons Committee of the Town Council have reported: "That they have received an application from the Cambridge Electric Supply Company, Limited, for permission to erect poles to carry an air line across Laundress Green and Sheep's Green to enable them to supply current to the skating ground in Grantchester Meadows. Your committee recommend that the request of the company be acceded to upon condition that a payment be made of 1s. per pole, that the poles to be so constructed as to prevent boys from climbing them and so coming in contact with the air line and that they be removed at the end of the season." Alderman Redfern moved, and Councillor Rae seconded, the adoption of this report. Councillor W. F. Taylor said that he had no wish whatever to stand in the way of the success of the electric light company, or of persons who wished to see the light; but he certainly thought on those open commons lads might by chance climb the poles and pull them down if they were only of a temporary character, and cause the death of several persons. It was a very serious question, and he could not understand why it had been taken away from the Paving and Drainage Committee to the Commons Committee. Alderman Dr Porter suggested that the proper course would be to invite the opinion of Prof. Ewing as to the advisability of carrying a wire of that kind across the two commons. He understood that it would be an extremely dangerous thing, and he thought the opinion of an expert ought to be taken. It was ultimately decided to refer the matter back to committee.

Bowness.—The clerk has laid the electric lighting agreement before the Urban Council. Mr. Garnett said he wished to draw attention to a nuisance in the telephone system by a buzzing noise which was caused by the electric light system when the current was turned on at nights He believed the nuisance could be stopped; it had been cured in London. Mr. Logan said they had nothing to do with it. The Chairman said with reference to the agreement they had had the opinion of an expert on it, and he

Digitized by Google

would therefore propose that it be accepted for the ensuing two years. The £120 which it had been agreed should be paid by the Council if the lighting were satisfactory, had not been paid, and it was proposed that it should not be paid for a period of six months, when the lighting should have worked to the satisfaction of the surveyor. The date of the commencement of the six months would be at the option of the firm, but he (the Chairman) understood that they were now in a position to work the lighting efficiently. But if the Council paid the money and the lighting did not work so well as during the period named, the firm should then refund the £120. The other main points of the agreement were that a payment of £1. 5s per lamp should be made for 1,000 hours light, and if more were burnt the Council should pay more, and if less then less should be paid. Messrs. Fell would also repay the Council £20 towards the salary of an inspector. The Council would also impose a fine, when the light was not burning, of 1d. per lamp per hour, as in London, in addition to making no payment That was a considerable item, as for the last month the Council would receive 38s. 3d. as fines. The agreement was then ratified

Monmouth.—The Town Council have received the following letter from the Local Government Board: "Local Government Board, Whitehall, S.W., November 11, 1895. Sir,—I am directed by the Local Government Board to advert to your letter of the 3rd ultimo, and to state that they have had under further consideration the application of the Town Council of Monmouth for sanction to borrow £20,000 for the purposes of their scheme of sewerage, sewage disposal, and electric lighting. On a careful review of the facts, it appears to the Board to be very doubtful whether the expectations which they understood that the Town Council have as to the advantages likely to result from the adoption of the scheme of electric lighting will be realised; but if, on further consideration of the matter, the Town Council are of opinion that the scheme which has been submitted should be carried out, the Board will not refuse their sanction to the loan. I am accordingly to request that the scheme may receive the further consideration of the Town Council, and that the Board may be informed of the decision arrived at. A copy of any resolution which the Town Council may pass in regard to the question should be forwarded to the Board. I am to add that before sanctioning the borrowing of money for works of electric lighting, the Board will require that the Town Council should obtain the approval in writing of the Board of Trade to the system proposed to be adopted for the supply of electrical energy, in compliance with Article VI. (1) of the Monmouth Electric Lighting Order, 1894.—I am, Sir, your obedient servant, C. N DALTON, assistant secretary. T. R. Oakley, Esq., town clerk, Monmouth." A meeting is to be called to discuss the situation.

Yarmouth.—The Corporation monthly statement of the electric light shows that the receipts were £245. 12s. 11d, yielding an excess over the cost of production of £104. 5s. 5d. From this has to be deducted repayment of capital, interest, depreciation, etc, amounting to £85 or £90 per month. Applications had been received from nine more customers for 302 lamps, making a total of 120 customers using 5,789 lamps. The Council's expert, Mr. W. H. Preece, recommended that, in view of the rapidly increasing demand for the light, it would be advisable to put in the additional boilers and dynamos in time for next winter supply; that, instead of two 150-h.p boilers, two 200-h.p. boilers should be put in, and that, instead of three 75-kilowatt dynamos, two 150-kilowatt dynamos be put in. This will increase the capacity of the station from 13,500 to 15,750 lamps, without counting the gas-engine, and the cost will not exceed the amount of the loan sanctioned. Messrs. Jewson and Sons wrote asking when the light would be introduced into Southtown and Gorleston. The Southtown Gas Company also wrote offering to fit incandescent burners into about 100 lamps and charge the same rate as at present, providing the Corporation undertook to use the lamps for at least three years. Mr. Press hoped the Corporation would not assent to any such arrangement for shutting the electric light out of Southtown, which contributed one-fifth to the rates and had paid one-fifth of the initial cost of establishing the electric light. Gas was dearer in Southtown, and no part of the town needed the electric light more. He moved that the application be not entertained. The matter was eventually referred to the Sanitary Committee with power to act.

Taunton.—The Electric Lighting Committee have reported that the new switchboard at the works was completed, and they recommended that a sum of £250 be paid to Mr Newton on account of his contract. They also presented to the Town Council the agreement with Mr. H. G. Turner for laying an electric cable and supplying electric light to Pinkhurst, and recommended that the common seal of the borough be affixed thereto. Alderman Potter, in proposing the adoption of the report, said that he had just received an order for 120 more incandescent lamps. Councillor Wrenn complained of the electric light being put out before the men went to work early in the morning, which was very inconvenient. The report was adopted. Mr. H. W. Couzens, the electrical engineer, reported that the demand for the electric light was steadily increasing as hitherto, and 140 lamps of 16 c.p. had been added during the past quarter. The new switchboard was at work, and proved of great value to them in regulating and controlling the circuits. They were daily expecting the engine and alternator, which were rendered absolutely necessary by the increasing load. They had erected all the additional arc lamps ordered last spring, and were now running half the public lamps till 6 a.m.; the remainder (in less prominent positions) were switched off at midnight. The severe storm of Tuesday last started two connections to earth on the older type of lamps, and extinguished a section of the lamps in North Town and Park street for about two hours. They experienced the greatest difficulty in locating the faults owing to the wind and rain. The maximum load on the private lighting circuits was about 20 per cent. greater now than it was in the corresponding period of last year.

Leeds.—The minutes of the Highways Committee of the Corporation have included a resolution of the Tramways Sub-Committee that the necessary steps be taken for the extension of the Roundhay tramway to the Canal Gardens at the Park; that the overhead electric system be continued from the junction of the Roundhay tramway at Sheepscar, along North street and Briggate; that in Boar-lane, from Briggate so the Yorkshire Banking Company's premises, an installation of the conduit system be laid; that the overhead system be then continued along Wellington-street and Kirkstall-road to Kirkstall Abbey, and that central poles be used wherever practicable. The Tramway Sub-Committee had also adopted a resolution that Dr. Hopkinson be engaged to report to and advise them on the installation of overhead electricity and the short length of conduit referred to, such report to be made in view of the Council's resolution to carry out the electric system throughout the city. These resolutions had been confirmed by the Highways Committee. Alderman Firth, in moving the adoption of the minutes, said the committee were intensely anxious that the very best possible principle should be adopted, and as the city engineer felt that it would be better in the interests of the city that a competent expert should be asked to report upon what was the best system, and how best to carry it out, the committee selected Dr. Hopkinson. Whenever his report was presented the Council would not be committed to anything beyond receiving it and paying Dr. Hopkinson's fee. The report would, he hoped, be brought before the Council in due course, but it could not be acted upon without the consent of the Council. An amendment moved was lost, and the minutes of the committee were in the end adopted by 32 votes to 18.

Rotherham.—Mr. George Gummer has moved in the Town Council the appointment of a new committee to be called the Electric Lighting and Tramways Committee. He said he was sorry the Mayor, in his opening remarks, had rather thrown a damper on such an enterprise. He supposed the Mayor's idea was that it might involve the town in an amount of expenditure, but at the same time omitting to take account of the circumstance that a profitable revenue could be derived from one, if not both, of the systems. The committee would have a good deal of work to go on with in its initial stages because before it could possibly get into a position for the spending of money enquiries would have to be made as to the wisdom of putting in installations for electric lighting, and enquiries would have to be made from the local authorities of Rawmarsh and other places surrounding Rotherham as to the desirability of running trams from their townships into Rotherham. In regard to electric lighting Rotherham was very much behind. At the last meeting of the Municipal Buildings Committee a resolution was passed to the effect that enquiries should be made and an estimate asked for relative to the probable cost of an installation for the new municipal buildings. He, however considered it was unwise for a municipal body to deal with so important a question in a piece-meal fashion. If they went into the subject thoroughly it was possible they might induce several manufacturers and large tradesmen to adopt the light, for it was undoubtedly the light of the future. He thought that, instead of spending a large sum of money on the extension of gasworks, they ought to look ahead. Regarding the trams, his view was that they were bound to bring the surrounding population into closer proximity by giving increased facilities of communication. This forward movement would, if pursued, materially help on the prosperity of the town. The resolution was ultimately passed by 10 votes to 2.

New London Mains, etc.—The Highways Committee reported to the London County Council on Tuesday that they had considered (1) three notices, dated respectively October 30 and November 2 and 12, 1895, from the House-to-House Electric Light Supply Company of intention to lay mains and construct surface boxes (*a*) in Bramham-gardens and Collingham-gardens, (*b*) in Courtfield-gardens and Collingham-place, and (*c*) in Fulham-road. The proposed work was for high and low tension mains, and they recommended that the sanction of the Council be given to the works. (2) A further notice, dated November 1, 1895, by the same company, of intention to lay low-tension mains in Earl's Court-road. The proposed work appeared unobjectionable. (3) Also two notices, dated November 4 and 12, 1895, respectively, from the London Electric Supply Corporation, of intention to lay distributing mains (*a*) in Tooley-street and (*b*) in St. George's-road. They saw no objection to the proposed works. (4) An application from Messrs. Ellington and Woodall for the Council's consent to the laying of the London Hydraulic Power Company's mains in Kingsgate-street and part of Eagle-street. The consent of the Holborn District Board has been obtained, and the committee were advised that the proposed mains would not apparently interfere with any of the Council's works. They recommended that the sanction of the Council be given to the laying of the mains. The Bridges Committee reported that the National Telephone Company had applied for permission to lay a cable along Waterloo Bridge. The company proposed fixing a 2½in. cable upon the east cornice of the bridge and within a segmental galvanised iron casing, 9in. in width at the base by 5½in. in height. The casing is to be flanged at the base and to be attached to the cornice by means of lewis bolts let into the granite. As so large a casing would probably interfere with the architectural lines of the structure, the committee were of opinion that the company should be restricted to the use of a 3in. tube as at Hammersmith Bridge. With

Digitized by Google

regard to the attachments, these should be made by narrow iron straps attached at intervals to the base of the plinth of the bridge, with the object of providing a means of drainage beneath the pipes. As to the rent to be paid by the company for the permission asked for, they suggested that an annual rent of £10 should be charged, which is the same rent that the Council charge the company for their cable across Hammersmith Bridge. The committee therefore recommended that the National Telephone Company be allowed to lay a telephone cable across Waterloo Bridge on the terms and conditions before mentioned.

PROVISIONAL PATENTS, 1895.

NOVEMBER 11.

21357. **Improvements in or connected with telegraphy and telephony, and in electric relays for use therewith.** Ernest Jules Pierre Mercadier and Henri Robert Joseph Pierquin, fils, 6, Lord street, Liverpool.

21367. **Improvements in electrical indicating and recording meters.** Reginald John Cumming Wood and Arthur Edward Mayes, 55 Chancery-lane, London.

21370. **Improvements in and relating to rotating brushes, applicable to moving electrical generators, motors, or machinery.** Sidney Allingham and Walter Angove Clatworthy, 1, Queen Victoria-street, London

21374 **Improvements in microphones.** Emil von Szvetics, 45, Holborn-viaduct, London.

21381. **Improved manufacture of carbon rods for arc lights.** Josef Roubal, 323, High Holborn, London. (Complete specification.)

NOVEMBER 12.

21433. **Improvements in the holders or carriers of electrical incandescent or glow lamps.** Richard George Evered, 7, Staple-inn, London.

21460. **Improvements in electric controllers and reversing switches for electric motors.** William Henry Morgan, 18, Buckingham-street, Strand, London. (Complete specification.)

NOVEMBER 13.

21498. **Improvements in carbons for electric arc lamps.** William Hastwell Clegg, 28, Broad-street, Birmingham.

21543. **Improvements in apparatus for transforming continuous electric currents into alternating currents.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la transmission de la force par L'electricité, France.)

21556. **Improvements in microphones or telephone transmitters.** William Phillips Thompson, 6, Lord-street, Liverpool. (The firm of Hammacher and Paetzold, Germany.) (Complete specification)

21560. **Improvements in and relating to electric railways or tramways.** John Charles Love and John Earle Hodges, 45, Southampton-buildings, Chancery-lane, London.

21586. **Improvements in electrical railway systems.** John McLeod Murphy, William James Dixon and Albert Francis Pierce, 40, Chancery-lane, London. (Complete specification.)

NOVEMBER 14.

20164A **Improvements in or connected with cathodes for use in the electrolytic deposit of metals.** Sherard Osborne Cowper-Coles, Maurice Ulcoq, Walter Murray Guthrie, and Carrington Riddell Gordon Smythe, 47, Lincoln's-inn-fields, London. (Date claimed under Patents Rule 19, October 25, 1895.)

21601. **Electrical apparatus for destroying rats and like animals** Lena White, 53, Arcade-chambers, St. Mary's Gate, Manchester.

21623. **Improvements in the fittings of electric lamps.** William James Fox, 53, Ward's-buildings, Deansgate, Manchester. (Complete specification.)

21638. **Improvements in electrical switches.** John William Fielding, 27, Martin's-lane, Cannon-street, London.

21657. **Improvements in or relating to submarine telegraph cables.** Francis Cornwall Crawford, 323, High Holborn, London.

21664. **Improvements in or relating to the running of alternate-current dynamo-machines in parallel.** Robert Henry Fowler and Charles James Hall, 433, Strand, London.

21679. **Improved means for use with electric cables for diverting the current through adjacent cables when required for repairs or other purposes.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

NOVEMBER 15.

21752. **Improved system of using electric lights and other means of illumination.** Goymour Cuthbert, 6, Bream's-buildings, Chancery-lane, London.

21759. **Improvements in electric storage batteries or accumulators.** Thomas William Allan, Arthur Powell, and Charles John Tibbits, 65, Chancery-lane, London.

NOVEMBER 16.

21763. **Improvements in electric tramway or railway systems.** James Fairclough, 10, St. George's-crescent, Liverpool.

21798. **Improvements in and connected with telegraph and other signals.** James Nicolson, 22, Glasshouse-street, Regent-street, London.

21817. **A new or improved apparatus for conveniently carrying portable electrical batteries, books, or other articles.** Thomas William Allan, Arthur Powell, and Charles John Tibbits, 65, Chancery-lane, London.

21818. **Improvements in fittings for incandescent electric lamps.** Thomas William Allan, Arthur Powell, and Charles John Tibbits, 65, Chancery-lane, London.

21830. **Improvements in electrical apparatus for firing fuses for mines and other purposes.** Siemens Bros. and Co, Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

SPECIFICATIONS PUBLISHED.

1889.

16237 **Electrical mains.** De Ferranti. (Second edition.)

1893.

19809. **Carbons for electrodes, etc.** Castner. (Second edition.)

1894.

20170. **Electrical soldering and welding apparatus.** Zerener.

NOTES.

A November Fog in London costs, it is said, in gas, electric light, accidents, delays, and damage, £100,000.

Electric Fire Hazard.—The committee of the Insurance and Actuarial Society of Glasgow, in connection with the "present-day applications of electricity, with special reference to fire risk," have made arrangements with Mr. T. Crichton Fulton, A.I.E.E., and the first lecture was to be given yesterday evening in the lecture theatre of the Institution of Engineers and Shipbuilders, at 207, Bath-street, Glasgow.

Cantor Lectures.—On Monday, December 2, Mr. Worby Beaumont will commence at the Society of Arts a course of three Cantor lectures on the subject of "Mechanical Road Carriages." The first lecture will deal principally with the history of the subject, the second with general principles, and the third with an account of the more recent efforts which have been made to develop a system of mechanical vehicles for common roads.

Unfortunate Fish.—According to *L'Etincelle Electrique* (November 20), if an alternating current such as is obtained from a Ruhmkorff coil is sent through water, large metal electrodes being used, any fish passing between them are temporarily paralysed, and come to the surface belly upwards. Our contemporary, who appears totally regardless of the feelings of the legitimate angler, suggests this as a new way of fishing.

Acetylene may give rise to an interesting legal discussion in the United States. The Standard Oil Company has taken up acetylene, and is preparing to push it; but the Pittsburg Reduction Company, which has aluminium works at Niagara, says that it makes acetylene as a by-product in the manufacture of aluminium, and that it is not going to be interfered with by any acetylene patent. It is possible, however, that the two companies may come to terms.

The Dalmuir Electric Launch.—Messrs. R. and A. M'Donald, the inventors of the "Clydebank" battery, tested their new electric launch "Mystery" on Friday and Saturday last. It is stated that they ran the craft from Greenock to Glasgow and back to Kilpatrick, a distance of 36 miles, with one charge of the batteries, in 5¾ hours, and that they used 36 cells made of ebonite, each cell measuring 12in. by 4in. by 4in., weighing 8lb., and having a capacity of, per cell, 300 ampere-hours.

Horseless Carriages.—A meeting for the purpose of forming an association in connection with self-propelled traffic is to be held on Tuesday, December 10, at the Cannon-street Hotel, London, at three o'clock, at which Sir David Salomons will preside. Sir David Salomons has secured powerful support in the movement. A series of resolutions will be proposed at the meeting with the view to starting such an association. Mr. Andrew W. Barr, of 30, Moorgate-street, London, E.C., is acting as honorary secretary for the time being.

Electric Carriages.—At the Stanley Cycle Show at the Agricultural Hall, Islington, horseless vehicles were on view in two distinct types. One was the Daimler carriage, a full-sized phaeton driven by a petroleum motor. The other type was an electrically-propelled tricycle of the Olympia pattern called the Gladiator, the electric apparatus being mounted on the frame in front of the rider, and geared down to the crankshaft, upon which cranks and pedals were mounted in the usual way, to enable the rider to assist in the work if he should so please.

Magnetic Surgery.—A remarkable use of magnetism was made a few days ago at the New York Eye and Ear Infirmary. A piece of steel ⅜in. by ¼in. had accidentally become embedded in a man's eye, and the nature of the injury was such that a surgical operation was held to be inadvisable. A strong electromagnet was procured and placed before the patient. When the man's eyes were brought within a few inches of the poles of the magnet he uttered a cry of pain, and the piece of steel came to the surface of the eyeball, whence it was extracted.

Ampere's Blackboard.—Ampère, like other philosophers, was noted for his absent-mindedness. It is stated that on one occasion while walking along the street he mistook the back of a cab for a blackboard, and as a blackboard was just the thing he needed at the time to solve a problem which had been vexing his mind for some moments during his walk, he made use of it. Taking a piece of chalk out of his pocket he proceeded to trace out a number of algebraical formulæ on the cab's back, and followed the moving "board" for the space of a quarter of an hour without noticing the progress of the conveyance.

Competition for Government Electrical Posts in Italy.—In connection with the new imposts on gas-lighting and electric energy the Italian Government found it advisable to open a competition for the posts of working electricians to the number of 20 for the new official department thus rendered necessary. *L'Elettricità* (November 24) says that considerable dissatisfaction is expressed by would-be competitors in good permanent positions, that after being successfully examined and taken on in the order of graduation they will have to undergo a period of probation lasting four months before the appointment is ultimately confirmed.

Boron Battery.—This new Austrian battery consists of a plate of zinc and one of carbon covered with boron, the electrolyte being a solution of "manganese salt and other substances"; the voltage is 2·5 to 3, which is maintained for quite a long time; the cost of maintaining the battery is said to be one penny for a 10-hour run—but for what output is not stated. The novelty consists in covering the carbon plates with boron, which is done by immersing them at a high temperature in a bath of chloride or fluoride of boron, then in a solution of oxalate of platinum, after which they are heated to a red heat in an atmosphere of hydrogen. A plate so treated contains metallic boron in its pores.

The Bell Telephone Monopoly, the *Electrical Age* says, is undoubtedly on the verge of its grave; it has struck a "snag" in the United States Supreme Court. That Court has decided that it has jurisdiction over the case of the United States *v.* the Bell Telephone Company to cancel the Berliner patent, which case was decided against the Government by the Court of Appeals. The Bell Company argued that this latter decision was final, but the Supreme Court decided otherwise, which action will result in bringing the case to the Supreme Court for final decision. This decision, the journal adds, is a substantial victory for the independent telephone interests, and there is much rejoicing in consequence.

Rubber Cultivation in the Straits Settlements. Not alone in coffee are the Straits Settlements leading the way, but also, it seems, in respect of the cultivation of rubber. A Ceylon paper has received a visit from the proprietor of a plantation in Lower Perak on alluvial river-side soil, where there are either planted, or about to be planted, some 500 acres of Para rubber. The progress of the clearing, and the eventual harvests of rubber made by the experimentalist, Mr. Baker, will be watched with interest. In the past two years, however, a good deal has been done in Para rubber in Ceylon, especially in the

Digitized by Google

Kalutara and other low-country districts. Perhaps 1,000 acres altogether are planted with rubber trees in Ceylon.

Talent for the Electric Railway Business.—A street railway manager in America is stated to have received the following interesting application for a "job": "dear sirs I have benadvized to write to you for A job on the St car as ime young and Active dear sirs if you want such A one please write me at once & Ill honest business & no other. ime young & if you need A hand & wish to try me ill go & if i dont do your work down me & get some one else I neve see A street car but ive neve tryed to do any thing with out strike at it ive been examined by & phenoligist & he said that I was suited up for mashinery & Ime ready to be ex amined by the best phenoligist if you wish to have me axamined please rite at once."

High-Voltage Shocks.—Signor Nizzola, in *L'Elettricista*, states that in the high-voltage plant installed in Frankfort-on-Main, a workman was carrying out some repairs in the distribution system when he touched a bare copper wire while standing in good contact with the ground. The wire was connected with the middle conductor of a concentric cable, the external conductor of which was maintained at about the same potential as the earth, owing to the capacity effects, the length of that circuit being 18 miles. He thus received a shock from 2,900 volts. He immediately fell to the ground, and remained for half an hour apparently dead. A bright spark was seen when he broke contact. Artificial respiration and throwing cold water on the breast gradually restored life, but he remained for a whole day in a dazed condition. He resumed his work again the next day, however, with no other effects remaining beyond a bad burn on the hand.

Turkish v. Persian Telegraph Poles.—An amusing story is told regarding the construction of a telegraph line from Bagdad, in Asia Minor, to the Persian capital of Teheran. The frontier line between Turkey and Persia was so indefinable that a track of no less than 17 miles of land over which the telegraph would have to be carried was in dispute, each of the two countries claiming the right to its possession. Now, the engineering stores supplied to the Turkish Government differed from those supplied to the Persian Government. The former had wooden telegraph poles, the latter iron ones. The Persian Government, in their jealous hatred of the Turks, feared that if wooden poles were erected across the disputed territory, posterity would regard them as proof that the territory was Turkish. On the other hand, the Turks objected to iron poles being used lest in the far future they should be adduced by Persia as evidence that the land was hers. The way in which the superintendent of the work contrived to get out of the difficulty did credit to his ingenuity and resource. He alternated the wood and iron poles for the whole 17 miles.

The Fastnet Cable.—The paragraph which has recently appeared in many of the daily papers relating to the breaking of the Fastnet Lighthouse and Crookhaven cable is, we understand, somewhat misleading. The communication is effected by means of the non-continuous cable system, first suggested by the late Mr. Willoughby Smith, and has worked satisfactorily for over four months. The system necessitates two short lengths of strong, bare copper cable being bolted to the rock from the lighthouse to the water's edge, and this can only be done when the sea is exceptionally smooth—a very rare thing at Fastnet. Owing, however, to the persistent bad weather, the cable down the north face of the rock could not be absolutely secured, and has, therefore, given way. Communication can be—and has been—maintained, except in the very roughest weather, by means of a temporary copper wire which the lighthouse men throw over the side of the rock so that the end just enters the water. The main cable, about nine miles long, which terminates at a mushroom submerged in the vicinity of the rock at a depth of about 80ft., still remains in perfect order.

An Electric Snow-Plough.—There has been on exhibition in Montreal a model of a new electric snow-plough to be used on street railways. It has attracted much attention, and has been endorsed by the city engineer. A steel scoop placed in front collects the snow. The scoop can be rapidly raised or lowered, leaving the required depth of snow on the street and between the rails. It can also be drawn across to right or left by a chain working on the shaft. The scoop projects about 6ft. over the side of the road from the rails, and clears the street for the vehicles. The removing plates are placed on an endless chain running around sprocket wheels placed at each end of the scoop, and, running across the scoop, draw the snow thus collected to the side of the road. Power to run the removing plates is taken from an electric motor placed on the platform of the car and conveyed by the chain to the sprocket wheel on the horizontal shaft, and thus by gear wheels to vertical shafts, on which are fixed the sprocket wheels, and around which the endless chain with plates runs. One scoop only is used at a time. On the return trip the car is switched on to the other track, and the back scoop, which is similarly fitted with plates, is used.

The Production of Pure Zinc.—An article by Herren Mylius and Fromm is abstracted in the *Electrochem. Zeit.* for October. To try to purify zinc by dry methods leads to no favourable results. The wet process can be carried out only with the aid of electrolysis, and this can be done in two ways—by the deposition of the metals from purified solutions with insoluble anodes, or by electrolytic refining with the use of soluble anodes of zinc. In their researches they used pure solutions of sulphate of zinc and obtained the following results: The pure zinc of commerce contains in all cases noticeable quantities of cadmium, lead, and iron. A solution of sulphate of zinc can be purified electrolytically so that chemical analysis cannot find any heavy foreign metals; zinc oxide is easily obtained by a chemical process, with the same purity; the electrolytic zinc obtained from zinc sulphate or oxide contains appreciable quantities of platinum which comes from the anode; the purest zinc is obtained by the repeated electrolytic reduction of the metal in basic zinc sulphate solutions, from which it is obtained in a spongy state, and must be melted in vacuum. The metal so obtained is not absolutely pure, but contains at least 99·99 per cent. of zinc. With the electrolytic decomposition of zinc the secondary decomposition of water cannot be prevented entirely. The formation of spongy zinc takes place by the action of the oxygen.

Death from Lightning.—The following appears in a letter to the *Lancet*: A number of soldiers at Aldershot were stationed under some small trees watching a cricket match when a sudden flash of lightning, like the bursting of a shell, was followed by cries for help from the men under one particular tree. Five men were found to have been more or less injured. No. 1, who had been sitting on the ground with his back against a tree from which a portion of the bark had been stripped close to his head, was dead; the breathing and pulse had ceased and artificial respiration failed to revive him. No. 2 was quite unconscious; the respiration had ceased, but the pulse was still perceptible. "In this case artificial respiration was rewarded after some minutes by a gradual return to consciousness." Brandy was then given; he was removed to hospital and soon recovered. Nos. 3, 4, and five recovered consciousness without artificial

Digitized by Google

respiration some few minutes after being struck. The state of the pulse and breathing during the brief unconscious period is not mentioned. All the four men were able to return to duty within a few days. It is remarkable that the man who was killed had no marks of injury on the head or face, but No. 2 had his hair singed, and there were marks of burning (like ecchymosis) on the left side of the face, neck, and upper part of the chest. These cases afford interesting illustrations of three degrees of injury from lightning shock. No. 1 was fatally injured, with simultaneous arrest of the heart's action and breathing; No. 2 was unconscious, with suspended breathing, but was restored by artificial respiration; and Nos. 3, 4, and 5, temporarily unconscious, probably with suspended breathing, recovered from the shock without special assistance. The practical lesson is that one man's life was saved by artificial respiration.

"Locomotive Carriages for Common Roads."—This was the title of the paper which was read at the Society of Arts on Wednesday evening by Mr. H. H. Cunynghame. Sir Frederick Bramwell was in the chair, and among those present were Sir David Salomons, Mr. Shaw Lefevre, Mr. Hiram Maxim, Mr. Thornycroft, Prof. Hughes, and Mr. Vernon Boys. Reverting to the consideration of the various sources of power that might be utilised for mechanical carriages, the lecturer said that while electricity had been successfully applied to tramways, its use for ordinary road locomotion presented greater difficulties. Accumulators were very heavy, and in the case of road cars that was a serious consideration. To supply 1½ h.p. or 2 h.p. for 10 hours they would weigh about 1½ ton, and a carriage with that load would have practically no carrying capacity. However, both in this and in other countries electrical wagons and road carriages had been constructed. Referring to the carriages that competed in the Paris-Bordeaux race, Mr. Cunynghame felt bound to say that as regards design there was much room for improvement. He was surprised to see the cog-wheels made with cast teeth instead of the proper epicyclic teeth cut from the solid, as found in good machinery. One of the best-known carriages at present was that of the Comte de Dion, which was a pretty little machine moved either by the feet or by an electro-petroleum motor, or both. To Mr. Shaw Lefevre, he said, was due the credit of having taken up the question in the last Parliament, and there could be little doubt that if Parliament saw its way to remove the present restrictions the foundations would be laid of a great and lucrative industry. In the discussion which followed, Sir F. Bramwell, Mr. Shaw Lefevre, Sir David Salomons, Mr. H. Maxim, and the Comte de Dion took part. The discussion was ultimately adjourned.

Metallic Sodium in Electric Conduits.—The discovery of metallic sodium in the conduits at St. Pancras was questioned by many experts at the time owing to want of care in collecting the deposit. It has, however, now been confirmed by similar finds at Boston. The case has been reported on by Messrs. Forbes and Glidden for the Boston Fire Underwriters' Union, and relates to the examination of a substance found in a casing of the electric mains in the basement of the Pray building. The report was published in the *Electrical World*. It appears from it that the substance discovered was impure metallic sodium mixed with partially disintegrated wood, the metallic sodium being the product of electrolytic decomposition of impure sodium hydrate. This sodium hydrate came from the cement mortar used in laying the brick wall of the basement upon which the wires were supported. Some of the hydrate may have worked its way through the wall from the cement used in the foundation of the adjoining paved street. The electric current which caused the electrolytic action was due to a leak inside the casing from one of the mains to another, the leak having been produced by the action of the sodium hydrate on the insulating covering of the wires. Inside the casing the wires were partially covered by an insulating tubing composed of tarred paper. When the front of the casing was removed, the wires, tubing, and woodwork about this point were found to be covered with a thick liquid which had dried in places to a whitish substance resembling discoloured salt, and was slippery to the touch, and strongly corrosive. The metallic sodium was smoking, and, when moistened and struck with any hard substance, it gave off flashes of flame. The substance was determined to be metallic sodium by its appearance and characteristic reactions, and by its colour in the Bunsen flame. The insulation where the deposit occurred was practically destroyed.

The Future of Engineering.—The first lecture for the season under the auspices of the Dundee and North of Scotland Institute of Mechanical Engineers has been delivered in the Technical Institute by Mr. D. H. Saunders, who chose as his subject "The Solved Problems of Mechanical Engineering the Earnest of a Still Better Future." He said that the difficulties connected with turbines in Scotland were greatly increased by the shallowness of the rivers, which in winter were "goured." In Russia, where immense supplies of pure water could be had at all seasons of the year, the turbine was extremely successful, and on small mountain streams in Scotland, for blacksmiths' and joiners' shops and other small industries, it was an admirable motor. When there was an irregular water supply, and where large numbers of workers depended upon unfailing regularity in motive power, the turbine, however, was valueless. Speaking of electric lighting, Mr. Saunders gave an interesting account of the costs, and showed that in Dundee for each £1 worth of electric light the cost of the coal was 3s. 4d., or one-sixth of the whole cost, while in Glasgow it was, owing to the very much larger installation, only 1s. 8d. per £1 of the whole cost, or one-twelfth. It was therefore only the difference between this one-twelfth and the cost of any new motor which entered into the possibilities of a cheapened motive power. There were several difficulties which, no doubt, recent inventions had tended to increase, and which greatly discouraged the engineer in his efforts to make free use of water power. What was wanted now was an accumulator which would absorb the irregular power of the wind and river, and give it back in regular and constant motive power. It was perhaps more a problem for the chemist than the engineer; but was it impossible that by the force of river or wind or tide, the gases of which water consisted could be separated and packed in sealed chambers under hydraulic power, so that they could become the motive powers of ships and machinery? If a cheap and good mode of transmitting electrical energy could be invented, it would lead to the abolition of smoke in cities and grant many other benefits. The lecturer next directed attention to the enormous possibilities connected with a horseless carriage, and described what he had seen of this class of vehicle on the Continent. He predicted that the next great triumph in engineering would be connected with the horseless carriage.

Electricity in Paris.—At the recent meeting of the Société Internationale des Electriciens an important paper on the central stations in Paris was read by M. J. Laffargue from the technical point of view, and M. F. Meyer, of the Compagnie Continentale Edison, from the commercial standpoint. M. Laffargue passed in review the existing Parisian central stations — the Compagnie Edison, the Société

Digitized by Google.

d'éclairage et de force par l'électricité, the Clichy, the Compagnie parisienne d'air comprimé et d'électricité, the Champs-Elysées, the Left Bank, and the municipal works. The Compagnie Générale Edison has just put down, in its station in the Avenue Trudaine, a group of Brown generators of 680 kilowatts, which will increase the capacity of the plant to 3,080 kilowatts. The Societé d'eclairage et de force par l'électricité is effecting alterations in its works in the rue de Bordy. It is installing a Corliss-Farcot engine and dynamo of 600 h.p. The company's total capacity will then be 2,685 kilowatts. The Compagnie parisienne d'air comprimé, etc., is establishing in the Quai Jemmapes a new station for five-wire distribution, using Siemens dynamos. This company will have installed during the present year 2,400 kilowatts. It aims at replacing its sub-accumulator stations, to the number of 25, by three or four more important sub-stations with rotary transformers. The total capacity of this company is 4,600 kilowatts. The Société du Secteur des Champs-Elysées is about to put down a new 400-kilowatt Farcot alternator. The Société du Secteur de la rive gauche (Left Bank) is building at Issy a works of a capacity of 4,000 kilowatts in order to distribute electrical energy by 3,000-volt alternating currents. At the end of 1895 there will, therefore, be in the central stations of Paris a total disposable power of 19,108 kilowatts for running 454,000 10-c.p. lamps and 154 motors absorbing 331 kilowatts. The maximum daily consumption in Paris during October, 1895, was 6,778 kilowatts—at about six o'clock in the evening. The total energy consumed in one day has reached a maximum of 45,500 kilowatt-hours. The increase in the rate of the annual consumption of electrical energy in Paris has been constant since 1889. The figures are the following: 1889, 480,784 kilowatt-hours; 1890, 2,284,405; 1891, 4,761,706; 1892, 5,987,538; 1893, 6,986,927; 1894, 7,883,434 kilowatt hours. M. Laffargue then spoke of the private installations, which have a total capacity of 25,760 h.p. He criticised, finally, the establishment of private installations, but was forced to admit that in many cases they were cheaper than the electrical companies.

The Proposed Light Railways Association.—A meeting of gentlemen interested in the subject of light railways was held on Wednesday at 17, Victoria-street, Westminster, for the purpose of discussing the desirability of forming a light railways association, and the lines upon which it should be established. The chair was taken by Mr. W. J. Carruthers Wain (the president of the Tramways Institute), and amongst those present were Major-General Hutchinson, Major-General Webber, Major Rasch, M.P., Mr. H. M. Acworth, Mr. J. Elliott (secretary of the Tramways Institute of Great Britain and Ireland), Mr. Rose-Smith, C.E., Mr. P. W. Meek, etc. The Chairman, in opening the proceedings, remarked that some confusion has arisen in connection with the meeting, owing, no doubt, to the conference convened for Thursday by the Parish and District Councils Association. He desired at once to announce that there was no feeling of hostility on their part towards that meeting. Though they recognised the value of the assistance of the local governing bodies, which was most desirable in the interests of the light railway movement, still these bodies, he thought, could not promote light railways. A suggestion had been made that a council of practical men should meet in conference. He (the chairman) had recently returned from America, where he had been studying the question of the working of light railways in that country, and from what he had seen it was manifest to him and others that light railways could be made remunerative. He mentioned that Mr. Ritchie had expressed his readiness to receive a deputation from the association on the 6th proximo, and asked for information as to the points to be raised and the name of the gentlemen constituting the deputation. He then moved a resolution which recommended that a light railways association should be formed. General Webber, who seconded the proposition, observed that at a recent meeting of the British Association at Ipswich he argued that light railways could be constructed at a cost sufficiently reasonable to make them remunerative, in spite of the diminished traffic in the agricultural districts. The resolution was unanimously agreed to. The following committee was then nominated: General Hutchinson, Major-General Webber, Mr. A. C. Payne, Major Rasch, M.P., Sir Douglas Fox, Mr. Hamilton Smythe, Mr. W. J. Carruthers Wain, Mr. R. Harding Milward, the Duke of Sutherland, Lord Wantage, Mr. Beachcroft, of the London County Council, Dr. Carte and Mr. W. M. Murphy, of Dublin, with power to add to their number.

The Society of Arts and Technical Education.—In the course of his recent address as vice-president and chairman of the council of the Society of Arts, Major-General Sir John Donnelly said that there was a distinctly felt want of something between school and the workshop or the counting-house. The movement, commencing with Mr. Ewart's Commons Committee of 1835 on art instruction, culminated in the Act of 1889. In a general survey it was necessary to note what was being done in elementary schools, where, since 1891, drawing had been compulsory for boys in England and Wales, and optional with girls when cooking was taught. In the year ending August, 1895, drawing was taught in England and Wales to about 2,000,000 scholars. In Scotland, without compulsion, 250,000 scholars took drawing under the Science and Art Department, as did 62,200 scholars in Ireland. Grants were made by the Science and Art Department for manual instruction given to 45,000 scholars. For this and drawing grants and cost of examinations the cost was £200,000 a year. The Department's payment on results amounted to about £150,000 for science and £74,000 for art, excluding examinations and the cost of the higher institutions, museums, and the circulation of loans. Excluding the geological survey and objects for which grants were made outside technical instruction, those for objects within its scope amounted to £492,000, in addition to £212,000 for drawing and manual instruction in elementary schools and science and art instruction in training colleges. Much was done for purely technical instruction in schools and colleges under the Admiralty and the War Office and in industrial schools under the Poor-Law Board. The review would be incomplete if mention were not made of what was done by the City and Guilds Institute, by the City companies, and by the provincial colleges. The data available showed that all the 49 county councils and all the 61 county boroughs gave aid to the subjects included in the Science and Art Directory, such aid amounting to £185,000 out of the beer money. To technological subjects—electricity, engineering, sanitary science, and others included in the City and Guilds scheme—£90,000 was given by 33 county councils and 41 county boroughs. To commercial subjects, £50,000 was given by 46 county councils and 39 county boroughs. Manual instruction was aided by 46 county councils and 43 county boroughs to the amount of £65,000. Local authorities might avail themselves of the admirable examinations and inspections of the City and Guilds Institute, but local bodies took advantage of them only to a slight extent. Last year only 218 classes were so inspected, and about 11,600 candidates examined. The Society of Arts examined

Digitized by Google

only 4,739 candidates, at 144 centres, in 11 commercial subjects. There were other examining bodies, Sir John Donnelly said in conclusion, but there was room and there was need for some central organisation to which local authorities might appeal.

Electric Locomotives.—Mr. Edgar Worthington read a paper on this subject before the members of the Manchester Association of Engineers on Saturday last. Countless experiments had, he said, been made with varied success to employ other material than steam and coal to haul goods and passengers upon a railway, but it had been left for electricity to make any serious encroachment on the domain of the steam locomotive. The last 20 years had seen such a rapid improvement in the construction of electric dynamos and motors that it would be rash to prophesy how far electricity would further supplant steam in the locomotives of the next 20 years. The commercially successful electric railway did not date further back than about 1886, when there were but 12 or 13 electric lines in the world. The year 1889 saw its introduction to Boston, U.S.A.—a city which in 1893 could drive 640 electric cars from one central station. The enormous development of electric tramways in America, Germany, England, France, and other countries had been principally in one direction—viz., by using an overhead conductor with a trolley running upon it connected to the car by a conducting pole. When he last visited America, in 1893, almost every town was provided with this type of electric railway running through the streets. The electric railways constructed by European engineers now numbered 81, with a total length of about 440 miles. There were 22 in Germany, 13 in England, and 11 in France. With regard to possible speeds, the lecturer said they were told that Mr. Weems, at Laurel (Mass.), ran an electric locomotive at 116 miles an hour, not long ago, using the overhead wire as a conductor. The subject of heavy electric locomotives was at present in an experimental stage and surrounded by practical difficulties which required the skill of the electrician's and mechanic's hand and brain before they could be pronounced commercially successful. The cost of operating electric tramways was frequently large during the initial stages, but, like every other mechanical contrivance, they ran more smoothly as they became better understood. The running expenses of the City and South London Railway for the first half of 1891 were 8·4d. per mile; for the corresponding half of 1893 they had fallen to 5·31d. The relative cost of operating tramways by electricity, horses, and steam, when each was in regular order, might be taken from the cost of three large typical tramways: electricity (City of London), 5·31d.; horses (Frankfort), 8·02d.; steam (Birmingham), average of four lines, 7·31d. They were thus brought to the conclusion that there was an important future before the electric locomotive. The chief direction in which it had been successful was in light suburban passenger traffic, superseding not only the horse trams, but also the ordinary railways. It was frequently spoken of as the "poor man's means of travel," and the thickly-populated counties of England seemed to be a promising field for its introduction. For underground service it was an assured success. Where water power was available, or an electric supply was already in existence, the working expenses of electric tramways were low. Even without these advantages the operating expenses of a frequent but not crowded service were lower than those of horse or steam worked tramways. The railway companies would, he thought, act wisely in developing electric feeding lines in thickly-populated districts, otherwise new competing electric railways were likely to spring up which might deprive the older companies of much of their local traffic.

Water Rheostats.—Mr. Geo. T. Hanchett says that many practical men do not know how universally water resistance may be applied, both for temporary and permanent service, in electric lighting and power work. It is often the case that a resistance of some kind is greatly desirable, if not absolutely necessary, and a few practical suggestions concerning the use of water resistances in such cases may not, he thinks, be amiss. The fluid in a water rheostat is not wholly water, as the name might imply, but consists of a mixture of water and some acid, usually sulphuric, which is added to vary the specific resistance. As the range obtainable by this procedure extends from one-tenth of an ohm, or even less, to several thousand ohms, the flexibility of the device is obvious, and it is practicable to prepare a water resistance to suit any voltage by varying the degree of acidulation. In the liquid are placed two terminal pieces, identical as to material, so as to obviate electrolytic action, and to these are attached the circuit wires. The proper shape and size of these terminals depend upon the volume of current to be passed through the device, and are also affected somewhat by the voltage. With large currents or very low voltage, or both, the terminals should be of large superficial area, and conversely. Water resistances are more often temporary devices, and therefore barrels, pails, etc., are frequently pressed into service. In cases where the apparatus is to be used for a few moments only, and the voltage is not dangerously high, a metal vessel is very convenient and satisfactory, the vessel itself constituting one terminal, and the other terminal being suspended therein. The resistance is decreased by gradually lowering the suspended terminal until it touches the bottom of the vessel, when the resistance is, of course, entirely cut out. However, it is not desirable to use any device in which the terminals tend to come together, except in cases like the one just mentioned, for the sudden removal of resistance from the circuit, caused by the accidental dropping of the suspended terminal, might result disastrously. A water resistance may be adjusted either by varying the distance between the terminals or by varying the terminal area submerged. The first method is preferable with heavy currents, and the second is better with small ones. The bulk of fluid necessarily depends upon the watts to be absorbed, regardless of voltage and current. For a steady load, free from sudden fluctuations, 20 kilowatts per barrel of fluid will be found to be a very satisfactory working figure. Experiment is usually the better way to determine how much acid is necessary, but for those who desire a guide to follow, the accompanying table is given:

Resistance of a Body of Liquid one square foot in Cross-section and 1ft. long

Pure water	about 100 ohms.
·174 per cent. acid	4·12 ,,
·435 ,, ,,	1·75 ,,
·724 ,, ,,	1·10 ,,
·985 ,, ,,	·85 ,,

The proportion of acid should be sufficient to enable the solution to absorb about one third the desired energy. The rest can readily be obtained by the adjustment of plates. In some cases, where a high voltage and a very small current are involved, as in voltmeter circuits, a water rheostat in column form will be found to give satisfactory results. Unfortunately, water resistances are prone to develop back E.M.F.'s., which preclude accurate measurements. To avoid this as far as possible in voltmeter circuits, a solution of zinc sulphate and two zinc terminals should be used. These, Mr. Hanchett says, produce a minimum back E.M.F.

LECTURE XVII.

(Specially Contributed.)

Erratum.—On p. 528, November 8, the electro-chemical equivalent of silver is given correctly in two instances, and in the other two a figure is omitted. In all cases read ·001118. By making the multiplication ·000010384 × 107·67 the student would have found the necessity of the missing figure.

Measurement by Magnetic Action.—Every wire carrying a current has a magnetic field, the intensity of which depends upon the strength of the current. When comparisons are to be made we must allow for differences of dielectric, but for our purpose we shall always assume that air is the medium in which the conductor or magnet is placed, unless the contrary is stated. Similarly, every magnet has its magnetic fields. Any magnetic field, whether that of a magnet or of a wire carrying current, resists the interference of any other magnetic field. The determining this resistance to interference of one field to another gives us one of the simplest means of measuring current.

Oersted — Ampere — Schweiger — Early in this century Prof. Oersted, of Copenhagen, thought, and in 1819 showed, that a magnetic needle—*i.e.*, a small magnet—suspended freely near a wire carrying a current was deflected from its position of rest by that current. Ampère investigated this, and expressed the results of this influence in the following manner:

Imagine an observer to form part of the conductor carrying the current, which passes through him, entering at his feet and leaving at his head, the deflection of a north pole will be towards his left hand if he is facing the magnet, as indicated in Figs. 1 and 2.

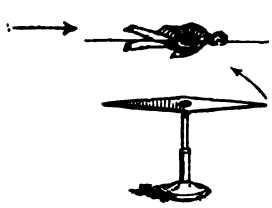

FIG. 1.

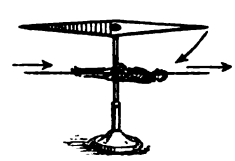

FIG. 2.

Prof. Schweiger, of Halle, soon after Oersted's discovery, by coiling the wire several times round the needle found that the deflecting force increased with the number of turns. This apparatus was called an electromagnetic multiplier, Fig. 3, and forms in some shape or other the basis of all our galvanometers.

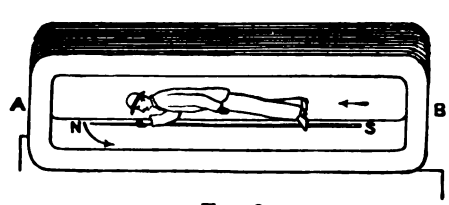

FIG. 3.

It may be mentioned here that the discovery of the action of a current upon a magnet is claimed for Grandominico Romagnosi, of Trent, who is said to have observed it in 1802 and published it in 1805. Anyhow it was a great discovery, and one that has been of enormous service to man. Successive inventors used the discovery in the construction of telegraphic and other apparatus, but not till recent years, when the idea of lines of force took hold of scientific minds, was any effort made to explain how the results were obtained.

A Stretch of the Imagination.—Writers of fiction make a great fuss about power of imagination; let us for a few moments enter their domain, and thus try to get a better grasp of magnetic interference. Then first try and imagine the earth as a magnet, its lines of force consisting of minute elastic threads stretching from north to south poles. These elastic threads are not so very very numerous through any square inch or square foot parallel to the plane of the magnetic equator. Mind, we imagine elastic threads, so that each thread, or part of thread, can be forced out of its original position. Each of these threads is to represent a line of force. Now suppose we make a small magnetic needle. This also has similar elastic threads, but the number of threads, or the number of threads through given area, is far feebler than that of the earth. It is evident that if we attempt to intermingle these elastic threads, the result will be, if the needle be free, that the elastic threads of the earth will force the elastic threads of the needle into a position parallel to their own, and that the poles of the needle will have the direction of the earth's lines. If we try to force the needle into any other position, the earth's lines oppose that force; hence we get two forces acting in opposite directions. Further, imagine a wire carrying current in proximity to the small magnet. The field of the wire imagine also composed of elastic threads, and far stronger than the field of the magnet or the field of the earth. The action of these threads is to try and turn the threads of the magnet into a direction parallel to themselves; similarly there is an attempt to force the earth threads into a position parallel to the threads of the wire. The earth's threads being elastic and those of the wire being stronger, the former are turned out of their normal course, and the small needle lines with them. Thus we get the earth's lines forced out of their normal direction, and the needle's lines, and therefore poles, following them. The extent of this deviation is a measure of the intensity of the current's field, and thus of the current.

Resultant Forces and Resultant Motions.—If we have a body or mass, M, acted on by a force F in the direction shown by the arrow, the motion of M, if motion there be, will be in the direction F, Fig. 4. If the mass, M, is

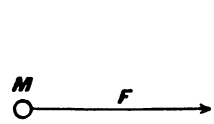

FIG. 4.

FIG. 5.

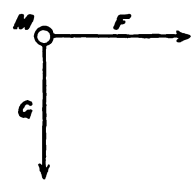

FIG. 6.

acted upon by a force G acting in the direction shown (Fig. 5), and there is any motion of M, the motion will be in the direction G. If, however, the mass, M, be acted upon at the same time by the forces, F and G, in the directions shown by the arrows, Fig. 6, the motion of M, if any, will be neither in the direction of F nor in the direction G, but in a direction somewhere between F and G, determined by the magnitude of the forces. If F is equal in magnitude to G, there is no reason why M should move in a direction nearer to F than to G, and, in fact, it would move in a direction midway between the two. If F is greater than G, then the direction of motion of M will be nearer F than G. If we represent the magnitude and direction of the forces acting by the length and direction of straight lines, we can easily geometrically, and in many cases easily arithmetically, ascertain the direction of motion and the magnitude of the one force which, acting in the direction of motion, would exactly replace the other two. Thus, if the mass, M, be acted upon by a force M F = 4 and a force M G = 3 in the directions respectively, as shown (Fig. 7) by

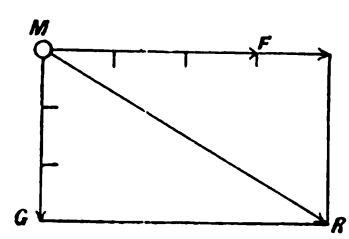

FIG. 7.

the arrows, then M will move in the direction M R, and the forces M F, M G might be exactly replaced by a force indicated in magnitude and direction by M R. The line M R is merely the diagonal of the completed

Digitized by Google

parallelogram M F R G, of which M F, M G form adjacent sides. M R thus represents what is called the resultant force, or the single equivalent force that would replace M F, M G, and this motion, M R, would be the resultant motion of the forces M F, M G. What I want to particularly impress upon you is the fact that the resultant makes an angle with the forces, and the magnitude of the angle with either force is determined by the magnitude of the force. You can draw lines to each to represent forces, complete the parallelograms, draw the diagonals, and see this for yourselves. I want to trespass as little as possible upon another branch of your studies, but must ask you to accompany me just a little further among these forces.

Couple—Moment of Couple—Torque.—Suppose we have a rigid body, B A (Fig. 8), and have two equal and oppo-

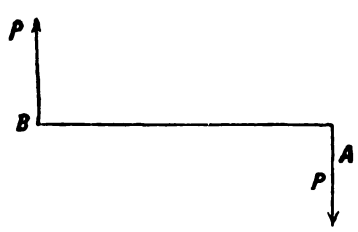

FIG. 8.

site parallel forces, P P, in the same plane acting upon this rigid body; the effect of those forces cannot be represented by a single force, for the tendency is to twist the body in direction of the plane in which the forces act. The term **couple** is applied to such a system of forces. The product of the numbers representing one force and the arm of the couple is called the moment of the couple. Thus, if P represents the force and B A the arm, the product P × B A = the moment of the couple represented. This applied to a magnet gives the force of one pole multiplied by the length of the axis of the magnet as the moment of the magnet.

A couple tending to twist a body in the same direction as the hands of a watch is termed a positive couple; if in the opposite direction, a negative couple. Electrical engineers use the term **torque** instead of moment of couple.

The Tangent Galvanometer.—Suppose we have a circular conductor, A B C D, placed in the plane of the earth's magnetic meridian, and suspend a very small magnet

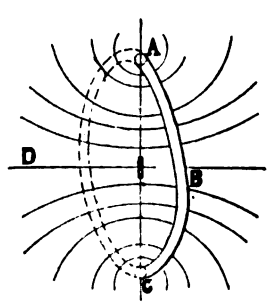

FIG. 9.

at the centre of this ring conductor, with its axis in the magnetic meridian, Fig. 9, then—

1. The lines of force of the magnet and the lines of force of the earth are parallel. Thus the magnet is at rest. Its poles being placed in the magnetic north and south so that it should be at rest.

2. If an electric current is sent through the conducting ring, the current produces its magnetic field around the ring, and the lines of force making the field of the conducting ring are at *right angles to the earth's lines of force and also to the magnet's lines of force.*

3. If the length of the magnet is small compared with the diameter of the ring—say, one-twentieth—we may take the field of the ring acting upon the magnet as a uniform field.

4. The effect of this conductor's field is to tend to turn the magnet, so that the lines of force of the field of the magnet are parallel to the lines of force of the conductor's field.

5. Hence we get two forces acting on the magnet:

   a. That of the earth's field tending to keep the magnet poles pointing north and south,

   β. That of the conductor's field tending to turn the magnet poles to a position pointing east and west.

The magnet, under these conditions, will move from its original position, and its poles will point in a direction that is neither north and south or east and west. The larger the current through the coil, the larger will be the deviation from the magnet's original position.

Now we are in a position to determine the law which governs the needle under the action of a current in the coil. It must be remembered that the action on one pole is equal and opposite to that on the other.

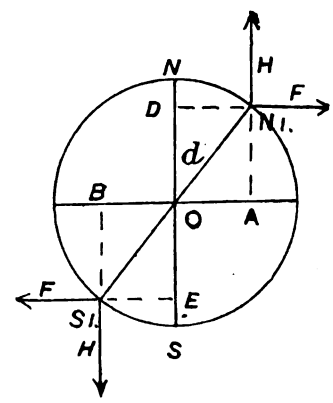

FIG. 10.

Let N S, Fig. 10, represent the magnet in the plane of the coil, both magnet and coil being in the plane of the magnetic meridian.

Let N_1 S_1 be the new position of the magnet when a current is sent through the coil.

Let *d* be the angle through which the needle is deflected.

H, as usual, is the horizontal intensity of the earth's magnetism.

Let F be the force due to the current.

Then the moment of couple due to earth's magnetism = H × A B.

And the moment of couple due to current = F × D E.

But when the magnet is at rest these couples are equal—that is,

$$F \times DE = H \times AB;$$

whence

$$F = H \times \frac{AB}{DE};$$

$$= H \times \frac{AO}{DO};$$

$$= H \tan d,$$

which gives the law: "The magnetic force which, acting at right angles to the magnetic meridian, produces on a magnet the deflection, *d*, is equal to the horizontal force of the earth's magnetism at that point multiplied by the tangent of the angle of deflection."

At any one place H may be taken as constant, hence the current varies as the tangent of the angle of deflection. It must be noted that the strengths of current are relative only. Currents can thus be compared with one another.

In using a tangent galvanometer the aim should be to get deflection as near to 45deg. as possible, because this is the most sensitive deflection of the instrument. If two currents are to be compared, obtain deflections as near as possible at equal distances on the two sides of 45deg. Thus, if it is desired to get a current double of another, let the apparatus be so arranged as to give with the smaller current, say, a deflection of 30deg.

Tan of 30deg. = ·5773503.

A current of double strength will give a deflection in degrees of which

the tan = 2 × ·5773503 = 1·1547006, or 46deg. 6′ nearly.

To obtain the value of the current in amperes we must know the constant of the galvanometer (which is $\frac{r}{2\pi}$ with one turn of wire in the coil, and $\frac{r}{2\pi n}$ with *n* turns in the coil) and divide by 10 because the practical unit of current

Digitized by Google

is one-tenth of the theoretical or absolute unit. The formula for amperes becomes

$$C = \frac{r}{2\pi n} H \tan d \frac{1}{10}.$$

Such a galvanometer as that described, however, is not suitable for engineering work.

We may represent by means of a diagram (Fig. 11) the relation which exists between the current strength and the angle of deviation. The action of the earth's field *may be taken as constant*, though as a matter of fact it is rarely constant except through minute periods of time. Represent this

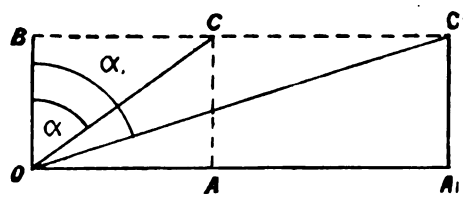

Fig. 11.

action by the vertical line O B. The current field acts at right angles to the field of the magnet, and as the strength of the field is proportional to the strength of the current, we may represent it or the current by the line O A. Complete the parallelogram O B C A, and draw the diagonal O C. The resultant of O B, O A, or the one force that would replace O B, O A, is represented in direction and magnitude by C O, and the deviation of the magnet by the angle α.

If we double the current strength it is then represented by O A_1, and the resultant force is now represented by C_1 O, and the angle of deviation by α_1. If this diagram was to scale, of course the arithmetical value of tan α_1 would be = 2 tan α.

In order to save the trouble of examining a table of tangents and making these arithmetical calculations, the instrument makers frequently give scales on their instruments for direct reading. The divisions on these scales are unequal, and obtained from this tangent law.

(To be continued.)

THE REACTANCE SYSTEM OF ARC LIGHTING.*

BY WILLIAM SMITH HORRY.

1. It cannot be denied that there is some room for improvement in arc lighting. The numerous and comparatively small dynamos, each supplying its own line, is quite out of place in a large arc light plant, and these, besides being theoretically inefficient, give more trouble and take up more room than would one or two large generators each capable of supplying a whole city in a business-like way. Our other electrical industries have all been greatly improved by the systematic use of large and efficient generating units at the station. The series arc lighting system alone has been left unimproved in this respect, and this industry may therefore be looked upon as being still in a state of transition.

It would be difficult, in the present state of the art, to design an arc light station capable of the lighting of a large city in any way comparable for economy to, say, an incandescent lighting or electric railway plant, for the reason that our manufacturers have not yet given us a comprehensive system of arc lighting. What we have now is good as far as it goes. Our half acre of dynamos, etc., is all very well, but surely something better is coming.

It must be admitted that the alternating arc lamp has done much to settle many problems connected with the supply of commercial arc lights; its introduction has been rapid and satisfactory, and it bids fair to become more used in the future as its economy becomes more appreciated, but for street-lighting with transformers there are still some hindrances to its use, and at present the series system is the only one that need be considered for this class of work.

2. A method of working arc lamp in series from the primary circuit of alternators without using a transformer, resistances, fuses, etc., to each lamp, and which is quite comprehensive enough for modern times, since a whole city can by this method be lighted from one machine, may be deemed of sufficient interest to warrant this description. The generator employed is the ordinary alternator that we are so familiar with in transformer lighting, and the lamp is also the ordinary constant-potential alternating arc lamp; and neither is changed in any way, so that different types of lamps, as of dynamos, are unnecessary. One lamp, and that of the most simple construction possible, is substituted for all purposes.

The type of lamp alluded to has already been brought to a high state of perfection, and it is, moreover, the most simple and elementary lamp that can be conceived. It has but one solenoid which is in series with the arc, no shunt spool, no cut-out, and is very reliable in consequence of having so few parts. These can now be procured in such sizes as to run for as many as 16 hours on this system without new carbons, and all-night lighting with this lamp becomes a fact.

If a choke coil, properly designed, be placed across the terminals of such lamps as these, arranged in series, each lamp will be found to regulate perfectly if the voltage at the end of the series be kept constant. The lamps, if of 1,200 c.p. will be found to take about 30 volts each. The choke coil need only be a small one, and need weigh but a few ounces. It consists of a little core of highly-laminated iron wound with wire in such a manner that the passage of even a small current will magnetise the iron very highly. The arrangement is shown in Fig. 1.

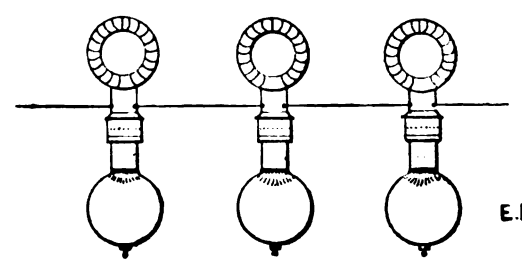

Fig. 1.

For practical work, however, thick wire must be employed, so that when the carbons are all burned away, the winding will take the whole lamp current continuously without injury to itself. Such a coil fitted to a lamp of 1,200 c.p. will weigh about 3lb.

3. Upon this principle the "reactance system" of arc lighting has been founded and so named because the reactance of a secondary or derived circuit causes the regulation of the lamp which is installed in series with others in the primary line.

The precise mode of operation is radically different from any other system. We have a line of many arc lamps in series, so that there is to all intents and purposes a constant current passing. Each lamp has a choking coil across its terminals, in shunt with the arc, so that there are two paths for the current, one between the carbons and the other round the impedance coil. With only a few volts difference of potential at the terminals, the current will be all choked out of the coil and all will pass through the arc, it lighting up the lamp the instant the current is turned on. As the carbons burn away the voltage at the lamp terminals will rise and the little coil will begin to leak. The impeding or choking power of an induction coil breaks down as the iron composing its core approaches to magnetic saturation. The result is that the arc is robbed of some of the line current, and therefore the lamp solenoid releases its hold on the carbon and causes the lamp to feed. It is found in practice that this device is very thorough. It takes care of the lamp whatever happens—makes it start up at once, keeps the voltage on the arc constant, and the lamp carbons may be open-circuited or short-circuited without any damage accruing to either the lamp or the line.

4. These are new effects in series arc lighting. There was never before such a controlling device, which containing absolutely no mechanism, yet at the right time performs the functions of a starting box, transformer, shunt solenoid,

* From the *Electrical Engineer* (New York).

Digitized by Google

automatic cut-out, and line compensator, and which is possessed of all the qualities necessary to perform each of these duties at the right moment and with unfailing certainty.

To give an idea of the current that passes through an arc lamp when this regulating coil is employed in shunt with it, a table is given below, and a diagram (Fig. 2) illustrates it graphically.

Amperes actually passing through the arc.	Volts at terminals of lamp.	Observations.
12	0	Carbons touching.
11·2	20	—
10·8	25	—
10	28	Lamp working properly.
9·4	30	
9	32	—
0	36	Carbons separated.

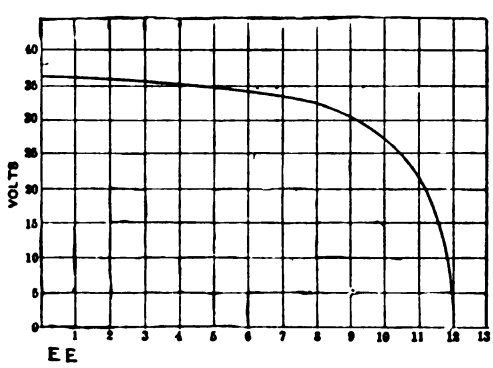

FIG. 2.

These measurements were taken on a line of 35 lamps arranged in series as in Fig. 1, working at 133 ⁓ from the primary circuit of a 1,000-volt alternator. The line current in this instance was 12 amperes. It may be remarked that in this case it was necessary to employ a 12-ampere line, as by this means the lamp started up very perfectly, and never failed to burn.

The line adopted in the "reactance" system, however, is generally 10 amperes, and a diagram of the circuits is shown in Fig. 3. In this way a 2,000-volt alternator will run 60 lamps in series each of 1,200 c.p., though in practice, over eight miles of No. 8 wire, it was found that only about 52 could be run in one series.

The system is automatic over a very wide range. Thus, if in a line of 30 arc lamps, five are extinguished in consequence of the carbons having all burned away, the remainder will run on just the same and the ampere-meter at the station will not be sensibly affected. This automatic regulation is a very good feature of the system, and it amounts in practice to 33 per cent. of the lamps for which the line is adjusted.

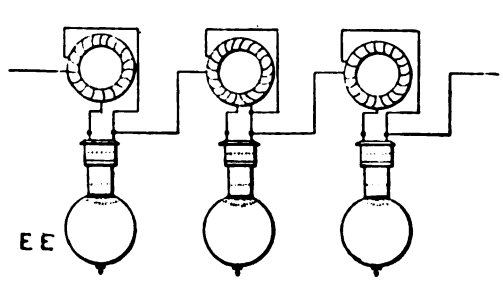

FIG. 3.

5. The efficiency of the device may be dismissed with a very few words. The amperes that flow through the coil are almost entirely wattless, and the whole device is exceedingly efficient. A wattmeter measurement shows the coil to consume about seven watts, and small though this may appear, the measurement has been taken again and again, with the most perfect instruments, with the arc lamp working, and its correctness is beyond question. This applies only to the coil employed with a 1,200 c.p. arc lamp; with a full 2,000-c.p. arc lamp the loss is about 40 watts, because in the case measured the arc-regulating coil had to act as transformer as well. The iron in the core of course gets hot, and for this reason only very little iron is employed—highly saturated.

The switchboard employed with the reactance system is shown in Fig. 6. It consists of an ampere-meter and a pilot lamp—10 amperes—a double-pole switch, a fuse block, and a series of contacts for throwing more or less impedance into the line. Lamps of 1,200 c.p. are installed as in Figs. 4 or 5, but larger arcs are generally fitted as in Fig. 4. It may be pointed out that lamps of widely different power can be connected in the same line, and that though the voltage on a 1,200-c.p. lamp is about 30, the larger arcs work better with less, say 24, and that only on this reactance system is it practical to give each lamp the voltage best suited to its needs at all times.

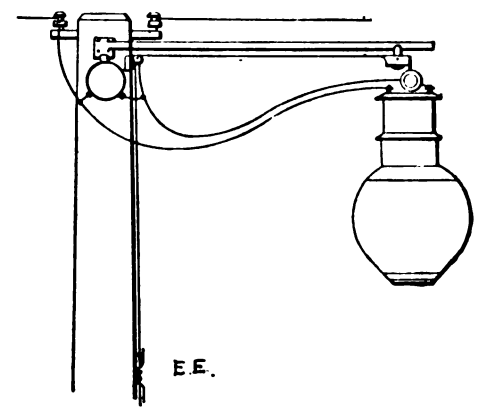

FIG. 4.

But the most important item of all, more important even than high efficiency, is certainty of operation. In this respect the "reactance" system leaves nothing to be desired. The coils cannot burn out, as they will take the whole lamp current without injury. Lightning cannot hurt them. There are no fuses to blow or to attend to. Altogether, the system is as hardy as it is possible for it to be. It is also possible by this system to use a carbon of great length, and to regulate it so that the length of the arc is invariable, whether these carbons be just lighted or nearly all burned away; and the arc regulators being so small the period makes little difference. A little larger core is all the change necessary for a regulator to work with 60 ⁓ instead of 133 ⁓.

It is obvious that any number of lamps can in this way be run from one alternator. Step-up transformers can be employed to run 100 or more arc lamps on one line or with two lines double that number. For indoors, one

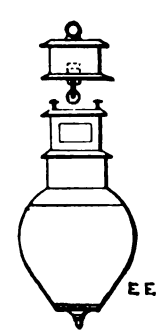

FIG. 5.

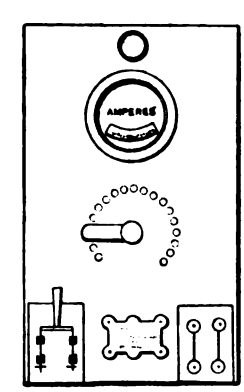

FIG. 6.

large building is lighted with 10 arc lamps supplied, as in Fig. 5, from a transformer secondary circuit of 300 volts. This greatly simplifies the wiring. The system works equally well on a constant alternating-current dynamo or on a constant-potential machine, and the lamps can all be worked on the secondary constant-potential circuit, if necessary, in the ordinary way.

It is considered a great gain to dispense with the cost of transformers for street-lighting, and it is hoped that when the extreme economy of the "reactance" system is appreciated, it will be found to be an improvement on existing practice and a step forward in the right direction.

LARGE ALTERNATOR AT DEPTFORD.

The Deptford station of the London Electric Supply Company was originally designed to be the home of large generators. Although some of the earlier projects for the building of gigantic alternators direct coupled to engines of the marine type failed to be realised, the station has for years held the British record for the alternator of largest output driven by ropes. The enterprise of the company has again been exemplified by the laying down of what is certainly the largest direct-driven plant in Europe. This alternator, which, it is interesting to note, has been designed and manufactured by the originator of the Deptford station, Mr. S. Z. de Ferranti, is capable of delivering 1,000 kilowatts at the high pressure of 10,000 volts when running at a speed of 156 revolutions per minute. It is coupled to an engine, made by Plenty and Co., on the lines suggested by Mr. P. W. D'Alton. This engine consists practically of three vertical compound tandem engines working on to three cranks at 120deg. As a consequence, the turning moment is exceedingly evenly distributed over the different parts of the revolution. The foundations required by this large set are placed on the site originally intended to contain the projected 10,000-kilowatt set. The foundation block stands on the original floor, which consists of a 6ft. layer of concrete. The size of the foundation required will be gathered from Fig. 1, which shows the concrete block before the machinery was placed on it. The weight of concrete in this block reaches the enormous figure of 360 tons. The illustration shows the access provided to get at the foundation bolts and into the alternator-pit. The surface of the block, as will be seen from the views of the complete plant, is somewhat below the floor-line of the adjacent parts of the engine-room, but the platform round the plant will be more easily kept clear from obstructions in consequence.

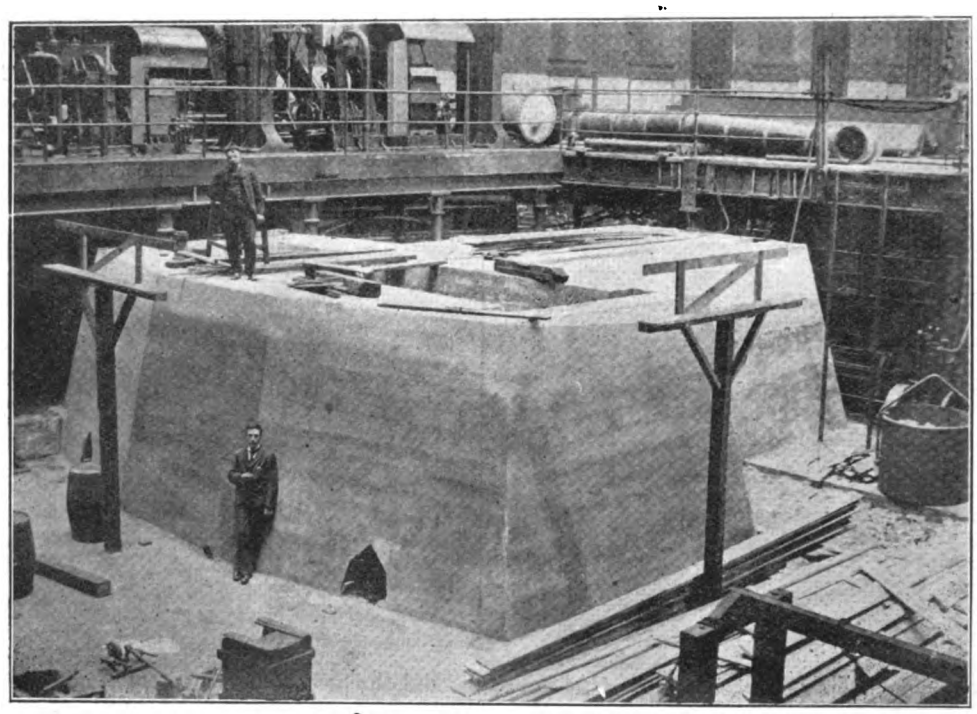

FIG. 1.—Foundation for the Large Steam-Alternator.

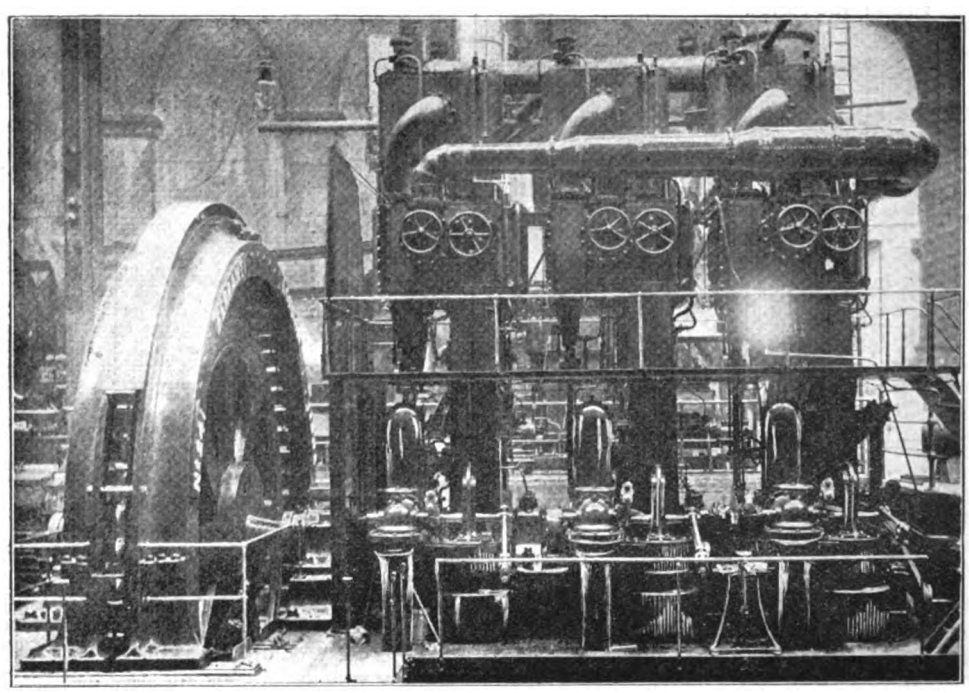

FIG. 2.—Side View of 1,500-h.p. Engine, showing Air-Pumps, etc.

The design of the engine shows Mr. D'Alton's appreciation for the essentials of the good parallel working of

Digitized by Google

alternators. The rest of the engines in the station show progressive steps towards an even turning moment. It will be of interest to briefly refer to these. The worst offenders are the two horizontal engines of the Corliss type, which drive by ropes the two 500-kilowatt alternators, which were originally used in the Grosvenor-square station.

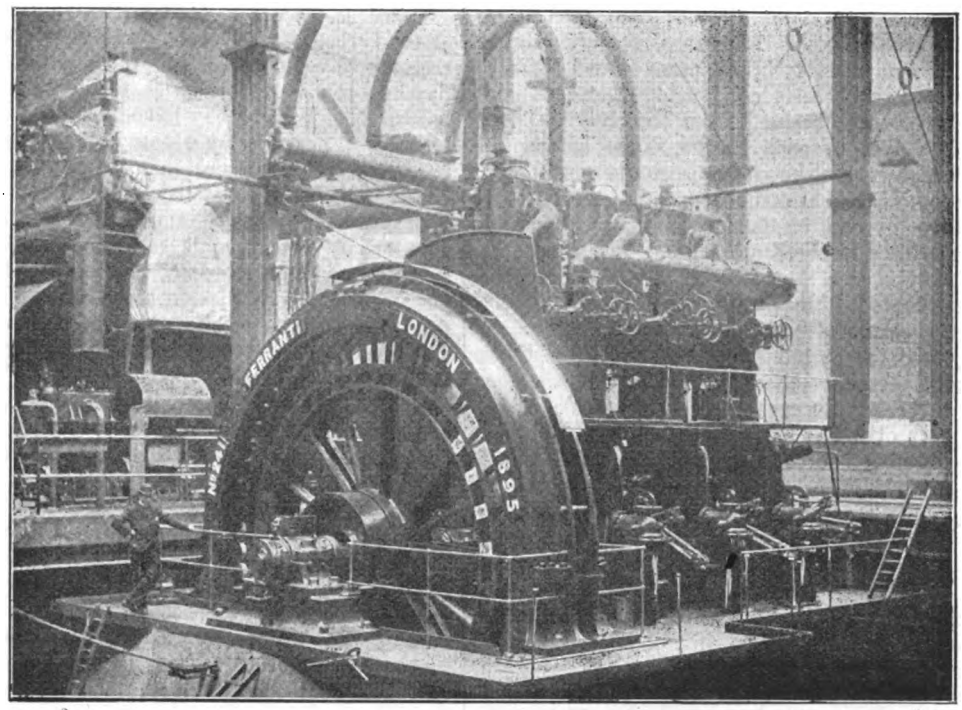

FIG. 3.—General View of the 1,000-K.W. Alternator.

These engines, being of single-crank type, with tandem cylinders, give a most irregular crank effort. The light-load plant consists of two 225-kilowatt Ferranti alternators geared by ropes to two 350-h.p. engines by Plenty and Co. These engines are triple expansion, and have three cranks at 120deg. At full load the work done in each of the three cylinders is nearly the same, but at light loads the high-pressure cranks do most of the work. The turning effort is then unsatisfactory. The remaining two sets are engined by the same firm with the marine type of engine, having a large rope pulley between the two cranks. These engines develop about 1,500 h.p., and drive the two 1,000-kilowatt alternators. They are compound engines, and hence have the fault that the division of work between the cylinders varies very largely with the load. The fact remains that, in spite of the widely-different designs of these three types of engines now in regular use, they all do work in parallel, and that when synchronised they hold in well. It is when switching out of parallel that the irregularity in the crank effort diagram is objectionable. The variation in turning moment causes a corresponding increase in the synchronising current, which represents the transference of power from one engine to the other, and keeps the machine in parallel. It then becomes almost impossible, owing to the oscillation of the ammeter needle, to determine the correct moment for switching the lightly-loaded alternator out of circuit. With practice and the care exercised at Deptford the recording voltmeter shows but a slight kick when the machines are taken out.

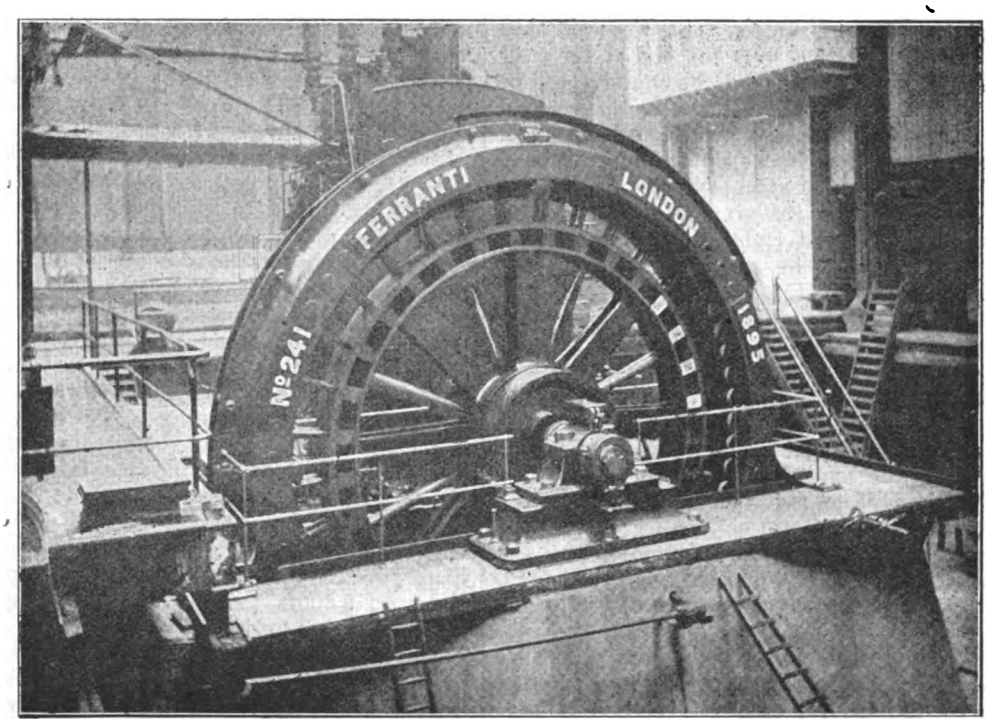

FIG. 4.—End View of 1,000-K.W. Alternator.

The new engines were designed with a special reference

Digitized by Google

to this question. They consist of three vertical compound tandem engines placed in line. The high-pressure cylinders are directly above the low-pressure cylinders, as will be seen from the side view (Fig. 2). The diameters of the cylinders are 16½in. and 37in. respectively, and the stroke is 26in. Each separate engine will develop 500 h.p. when supplied with steam at 140lb. All the parts have, however, been constructed to stand 200lb. pressure, as when heavy demand arises the boiler pressure is raised. Hence the engines can on emergency supply more than 1,500 h.p. The back columns are used as condensing-chambers, the water for the spray being obtained from the river. There are two exhaust valves to each engine, as can be seen in Fig. 2, one of which passes the steam into the condensers, and the other connecting to the atmosphere. The air-pumps are worked by rocking levers, the links to which are shown disconnected in the illustration. The valve gear is of Joyce's new type, the alteration in the throw of the eccentric being effected by hydraulic pressure. For this purpose the main crankshafts have a hole through them communicating with a cylinder in each of the three eccentrics. The pressure in these is opposed by a strong spring. The governor, by means of a hydraulic relay, varies the quantity of water in these cylinders, and hence varies the point of cut off in each cylinder. A small pump maintains the hydraulic pressure when the engine is running, and a hand pump is provided to move the eccentric over when starting. The high-pressure slide-valve is of the cylindrical type, the low-pressure slide-valve being flat.

The construction of the wheel on which the armature of the alternator is supported is deserving of special notice, both on account of the high circumferential speed at which it runs and the precautions adopted to make it perfectly safe. The details of the wheel are shown by Figs. 2, 3, and 4. Following the construction in order of building up, the first operation consisted of shrinking on to the turned shaft a steel boss having eight large radial holes drilled and tapped in it. The wheel itself is cast in two halves, each half having four double T-arms which rest on the boss. The inner end of these arms were not joined together in casting, so that each was free to move as contraction took place. These two halves of the wheel were faced at the joints, and are turned both in the rim and at the centre. The wheel is then secured in position by shrinking over the end of the arms two heavy steel rings. The ring on the one side can be easily seen in Fig. 2. The two halves are also bound together at the rim by shrinking oval-shaped straps of rectangular section over projections on the inner side of the rim. These straps are of steel, and have the same section as the rings securing the arms to the boss. The next step is the introduction of eight strong radial spokes of cast steel to help take the bursting stress. These have flanged heads let into the rim and screwed into the boss referred to above. The method of securing uniform stress in each of these is as follows: The eight spokes are screwed up as far as possible when cold, and then are carefully marked. A calculation is then made as to how much further they must be turned to give a definite strain in them. This position is marked, and the spokes are heated *in situ* till the expansion allows of their being readily turned in the position required. On cooling, therefore, each spoke exerts a uniform binding pressure on the rim. The design was based on the assumption that the wheel should carry twice the weight at twice the speed, and the careful workmanship has resulted in a wheel which runs perfectly true.

The armature of the alternator is built up on somewhat similar lines as in the older Ferranti machines running at Deptford, but with improved details. The internal segments have cores made of laminated brass and asbestos, keyed together by corrugations in the brass. The smaller end is of solid brass burnt on to the strips, and to this is connected the inner end of the bare copper conductor. The segment is then wound with the conductor, which has corrugations to prevent side displacement, and the adjacent turns are insulated by special fibrous material. Two adjacent segments are clamped together into one carrier, and the outside ends of these conductors are connected where they touch. The two bolts clamping them into the carrier then form the two connections to the segments. The insulation between the carrier and the coils is effected by micanite shields. The carriers consist of two heavy brass castings clamped on to the segments. The complete carrier is supported on two bolts projecting from the rim. The insulation of these bolts is a matter of the greatest importance. They are ebonised all over except at the thread. The heads, screwed on, which come in the rim are covered with ⅜in. of ebonite. The rim of the flywheel is cast with a series of chambers to contain these boltheads. When they have been inserted and are held exactly in position by a template, the surrounding space is cast in with a special insulating compound of sulphur. These bolts are then tested with 20,000 volts between the metal at the screwed end and the rim of the wheel. The whole armature is connected up into two parallel circuits in such a way as to prevent any large difference of potential between adjacent segments. The connections are made from diametrically opposite points on the armature. The one point is earthed by being connected on to the rim of the wheel, and the opposite point, which is at 10,000 volts above the earth, is led by highly insulated connection to a collector in the front of machine. The bolts supporting the carriers near the high-tension connection have extra insulation on them, consisting of a series of ebonite collars, which increase the length of surface liable to leakage. The field-magnet castings are built up in two halves, one supporting the magnets on each side of the armature. Each half is formed of four segments securely bolted together. The poles, of which there are 64 on each side, are of circular section, and are forced into holes in these castings by hydraulic pressure. The diameter of the poles is so arranged that the fit in the casting practically secures them, but they are also clamped by cup-shaped set screws. The field coils are constructed by winding bare copper strip on edge into a spiral, with insulation between adjacent turns. The whole of these coils are connected in series, and we are informed that at full load the machine will require about 1 per cent. of the full power for excitation. The section of the magnets is not increased at the pole-faces. The danger of the high voltage from the bare copper of the armature sparking across to the field has been overcome in this case by placing micanite caps over the poles. These caps, which are about ⅛in. thick, have all been tested up to 25,000 volts. Since being in use no faults have developed in them up to the present. The caps are enamelled on the outside, and even then have to be wiped all over after about every 24 hours of running to prevent surface leakage. To enable this to be readily done, the two halves of the field-magnet system are made to slide, and are moved apart by a screw gear driven by an electric motor. This electric gearing is placed on the edge of the armature pit next to the engine, and by means of it the magnets can be separated in five minutes. In fact, on a special occasion it was found that threequarters of an hour was all the time taken to separate the fields, to remove a defective segment, to replace it by a new one, and to bring the magnets back into the position for running.

Some idea of the size of the machine can be gained from the illustration, but the following few dimensions will be of interest in this respect: the outside diameter of flywheel is 16ft.; mean diameter of armature—*i.e.*, diameter of pole centres—20ft.; overall diameter, 24ft.; width of armature strip, ¾in.; circumferential speed of armature at mean diameter, 9,800ft. per minute. The copper loss in the armature at full load is ·85 per cent.

This alternator has been running for about a month now, and has been tested with 75 per cent. of the full load on it. A neat method of indicating the relative speed of the machine before putting it into parallel with the others is in use. A series of white patches are painted on the rim of the flywheel, opposite alternator coils, Fig. 4. The arc lamp, which can also be seen in the same figure, is then supplied from the other source of alternating currents. As is well known, the light given off by an alternating arc is not continuous, but fluctuates with the alternations. Hence, when looking at an object lighted in this way, a series of consecutive impressions is received on the retina. So, when observing

Digitized by Google

the white patches referred to, one really sees their positions at successive definite points on the current curve of the other alternator. If the two machines are absolutely in synchronism, the result is that the spots appear stationary. If there is a difference of speed, they seem to advance or recede according as to which machine goes faster. In this way the driver get a good indication as to whether his engine is at the right speed before the usual synchroniser is switched in.

It is a great pleasure to note that under the able supervision of the energetic engineer, Mr. D'Alton, the Deptford station is gaining load rapidly, so that additional machines are required. The regularity of the service, in spite of the transmission difficulties, is now justifying the original designs on which the station was projected, and the adoption of large units of plant has been supported strongly by the Continental firms. The actual output on Monday, November 18, reached the high figure of 13,000 Board of Trade units.

THE STONE SYSTEM OF LIGHTING RAILWAY CARRIAGES.

A new system of train-lighting, invented by Mr. A. B. Gill, has been taken up and developed by Messrs. J. Stone and Co., of Deptford. The London, Tilbury, and Southend Railway Company have had three trains fitted out on this system, after kindly allowing the inventor to experiment largely on a few coaches in order to test the new gear.

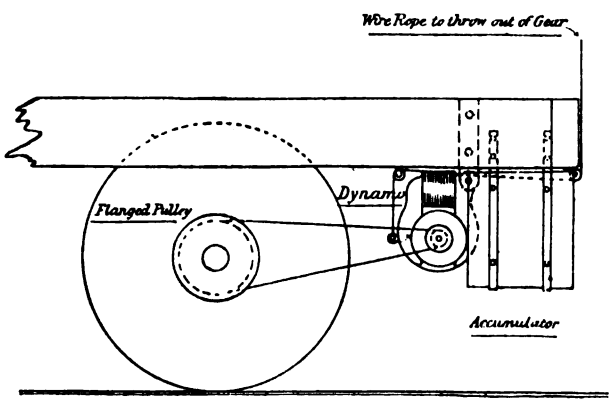

FIG. 1.

The main principle of this apparatus is exceedingly simple, and can be gathered from our illustrations (Figs. 1 and 2). A dynamo and a set of accumulators are provided on each coach, so that each is self-contained, and the train can be uncoupled without any alterations to the connections. The dynamo is hung on an axis under the carriage, and the necessary tension in the driving belt is obtained by the action of the weight of the machine. Unfortunately, this is not so clearly shown as might be wished in the diagram, Fig. 1, as when the machine is in the position there indicated the belt would have much more slack in it.

When the train starts, the dynamo, being geared by a link belt to the pulley on the carriage axle, gains in speed up to a certain predetermined value. Then a governor on the shaft completes, first, the shunt circuit, and then the main circuit of the dynamo, thus connecting it to the batteries and lamps. Now the automatic regulation begins. The machine is so balanced by a counterweight that the weight of the machine gives sufficient tension on the belt at that speed as to allow of a torque being given to the pulley corresponding to the required current in the dynamo. An increase in the speed of the dynamo would then mean increased torque, and this would move the dynamo towards the driving axle. But this movement would slacken the belt, and hence practically prevent an increased torque being given. As a result the belt slips, and the arrangement gives a constant speed as long as the current is constant. This device works exceedingly well, as far as could be judged from the carriages viewed on Wednesday last; but this problem in slipping belts is too new a feature to be approved without question. The dynamos are arranged to run at a constant speed corresponding to about 10 miles per hour, and then the belt speed is about 380ft. per minute. Hence at 50 miles an hour the belt is sliding on the pulley of the dynamo at four times this speed, or 1,520ft. per minute. Unless there is some new explanation as to the mechanical losses from slipping belts, we should conclude that at this speed the power taken from the axle of the carriage is five times that used by the dynamo. The pulley would hence be expected to get hot, but the cooling action of the air on the belt prevents this, as after a 20-mile run the hand can be held on the dynamo pulley.

The following are a few details of the system as applied to the carriages on the Tilbury line which carried the guests of Messrs. J. Stone and Co. to Grays and back on Wednesday last. The dynamo developed 25 amperes at a pressure of about 18 volts, of which current the lamps took 15 amperes. The remaining current passed into the accumulators, which keep the lamps alight when the train is standing. The eight accumulators are made by the Electrical Power Storage Company, and are of their E.K. type.

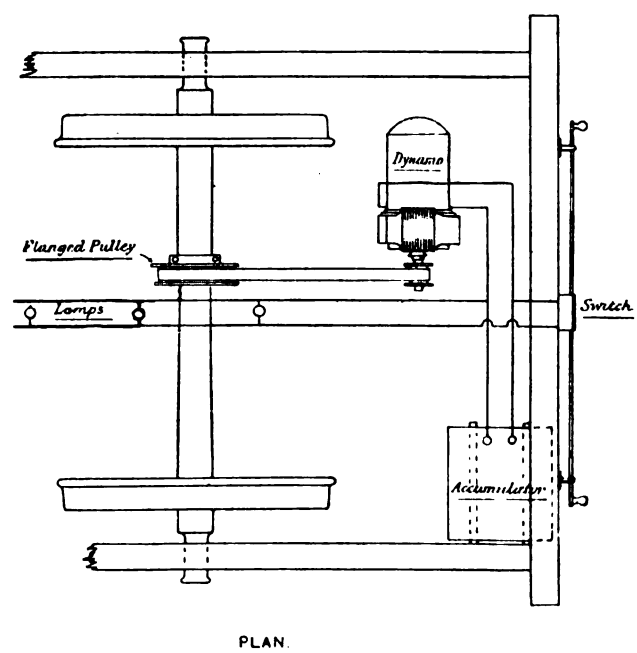

FIG. 2.

Their capacity is sufficient to keep the whole of the lamps in the carriage alight for four hours. The 16-volt lamps are arranged two in each carriage, and on different circuits, so that one half of the lamps can be switched off during long stops if it is desired to spare the accumulators. When the dynamo charges the accumulators, a resistance is automatically introduced in the lamp circuit. An accurately-made metallic cover is fitted to each machine, so that the working parts are kept perfectly free from grit and dust. This provision, combined with the fact that the capacity of the plant is ample for all requirements, reduces the wear and tear.

After the machinery had been viewed, the makers entertained their guests at the Holborn Restaurant. After the dinner and the usual loyal toasts, speeches of a most complimentary nature were delivered. Mr. A. B. Gill and the maker were congratulated on their new venture, which is already on trial on 18 different lines. The cost per carriage per outfit was stated to be about £50, but in the cost of upkeep a great saving is claimed over gas or even oil.

PHASE AND FREQUENCY TRANSFORMATION.*

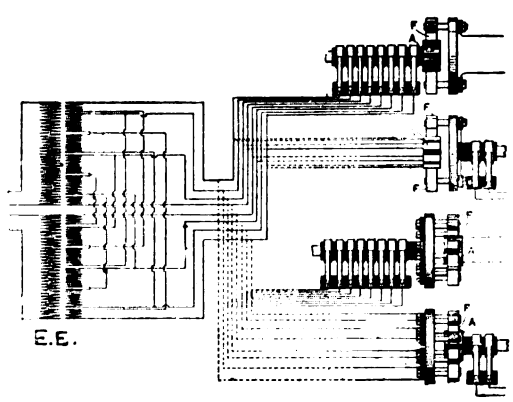
A patent has been issued to Prof. Henry A. Rowland on a method of varying the frequency and number of phases of polyphase currents. The object of the invention is

* From the *Electrical World* (New York).

Digitized by Google

stated to be to vary the frequency of polyphase currents from zero to any desired frequency; to produce means for starting synchronous and other motors and causing them to run at different speeds, and to accomplish with other translating devices a variety of results of like nature. This object is attained by means of the combination with a commutator, either stationary or revolving, of brushes, which also may be either revolving or stationary. The bars of the commutator are joined by conductors to the source of electricity, either directly or by means of contact rings or brushes, and the current is carried from the commutator by brushes, either fixed or revolving independently of the commutator; or the current may enter by brushes and be carried off by the commutator brushes. Currents may be taken directly from the brushes or commutator bars when they are stationary, or through contact rings or other brushes when revolving.

In the accompanying diagram four different methods described in the patent are illustrated. The transformers to the left are for connection with a two-phased system, and are each wound with six secondary coils, the length of the coils and the connections being so arranged as to produce an eight-phased system. The upper device to the right represents a revolving commutator and fixed brushes, the conductor leading directly from the brushes to the contact brushes of the motor or dynamo. The device below differs from this in having the commutator stationary and the brushes revolving. The third device shows a lead of conductors somewhat different from the upper one, while the lower one shows a lead somewhat different from the construction given in the second device.



A continuous current will be carried off by the pairs of conductors to the right in the diagram, provided the corresponding devices run in synchronism with the current, while an alternating current will be carried off at any other relative speed, the polyphased current from the transformer being converted into a continuous or alternating current by means of the commutator, A, and the brush, F, either or both of which may be made to revolve. The speed of the commutator necessary to produce continuous currents can be reduced one-half, one-third, etc., by making the number of the commutator bars two, three, etc., times the number of wires from the transformer. By means of the arrangement shown, therefore, it is possible to transform an alternating current of any number of phases or frequency to another alternating current of any desired number of phases or frequency, and to further change these latter currents, either into a continuous current or alternating current of a greater or less number of phases or frequency, and to run a synchronous or induction motor at any desired speed, to start the same under any load, and to accomplish many other results that would readily suggest themselves to a skilled electrician.

While objections to the system may occur to some, such as relate to sparking at the commutator, and practical means for securing the necessary invariable rotary speed of the commutator or brushes with relation to the periodicity of one or the other circuit, these may well await the appearance of an apparatus in a practical form. The method, if commercially applicable, will be one of such great value that it is sincerely to be hoped that we may soon hear of its having been put in shape to be submitted to test in actual industrial work.

THE BURNING OF MESSRS. CROMPTON'S WORKS AT CHELMSFORD.

As all the world knows, the greater portion of the Arc Works at Chelmsford, belonging to Messrs. Crompton and Co., was burned to the ground on the morning of Friday last. The fire was first noticed at twenty minutes to nine, while the workmen were at breakfast, and within two hours damage was done to the extent of £50,000 or £60,000. The origin or the cause of the conflagration is unknown. It was at first thought that the new switchboard was the source of the outbreak, but Mr. Crompton has since stated that this could not have been the case. We paid a visit to the scene of desolation on Tuesday. The shops totally destroyed were the machine-shop with the engines, the armature-shop, and the transformer-shop; those saved from the flames were the lamp-shop, the boiler-house, and the smithy. The gutted portion of the works presented to the gaze a confused mass of fallen brickwork, twisted girders, and rusty and broken engines, dynamos, and other machinery.

One thing is certain—the flames spread with terrible rapidity, probably owing to the woodwork used in the construction of the buildings; and the men had not even time to bring the fire appliances of the works into operation. A curious feature of the disastrous conflagration was that the only heavy-tool part of the establishment that was unravaged by the fire was the little original or nucleus building of the works. A very severe loss is that of all the gauges, templets, standard measuring instruments, and drawings belonging to the company. Some of the workmen, too, have lost valuable tools. Fortunately, a year ago the accountancy department was removed to the London offices, and the chief business books of the company were therefore not at Chelmsford. Some newly-erected sheds, which were untouched by the fire, and which were to have been used for the manufacture of electric heating and cooking apparatus, will now be utilised for armature winding and other work.

At the time of the fire Messrs. Crompton were very busy, and were turning out on an average 130 arc lamps weekly. Some 650 men were employed at the Arc Works, and of these on Tuesday about 300 had been re-engaged, mostly for the barely-scathed lamp-room. On that day there was only a semi-portable engine at the works supplying power for the lamps; but there were three temporary or improvised stations—one in a field close to—deriving power from traction engines. The town of Chelmsford, which, unless we mistake, was the first in England to adopt public electric lighting, possesses two or three and twenty street arc lamps and about 13 miles of street incandescent electric lighting, nearly the whole of which Mr. Crompton expected to have running on Tuesday evening. Work in progress to the value of from £20,000 to £25,000 was destroyed, and the portion of the works and its contents ruined was insured for about £48,000. Amongst others, the company received friendly offers of aid from Messrs. Siemens, the Brush Company, the Electric Construction Corporation, Messrs. Marshall, Messrs. Scott and Mountain, and Messrs. Mather and Platt.

The local fire brigade performed very efficiently the work of combating and confining the area of the outbreak. In this arduous undertaking the borough surveyor of Chelmsford (Mr. Sasse) played a prominent part. He had a narrow escape of being badly hurt. He was standing near a large steam-pipe when it fell and burst, carrying away the upper portion of his hat and dashing him against a wall. This was practically the only casualty. Reverting to the question of the origin of the conflagration, Mr. Crompton states that he examined and passed the switchboard shortly before the outbreak, that the usual precautions were taken with regard to the switchboard, that there was no arc formed, and that the weight of evidence is against the switchboard having had anything to do with the fire.

A considerably exaggerated account of the damage caused by the fire having appeared in the local papers, Mr. Crompton has published a letter, in which he says: "Although the loss is serious enough, a considerable part of the works

Digitized by Google

remains intact, and we are still in a position to execute orders for our lighter goods, and we hope to be able to carry out our orders for heavy goods in a few weeks' time."

Messrs. Crompton have since informed us that the electrical heating and cooking department is not affected, as their London works are alone employed in the manufacture of the apparatus.

NEW PARLIAMENTARY BILLS.

In the ensuing session of Parliament the following local authorities and companies are applying for provisional orders under the Electric Lighting Acts—viz, the Bournemouth Gas and Water Company; Bexhill Water and Gas Company; Guildford Gaslight and Coke Company; Wells (Somerset) Corporation; Bath Urban Sanitary Authority; Newington Vestry; Devonport Corporation; Vestry of the Parish of St. Mary, Battersea; Ilfracombe Gas Company; Midland Railway Company, seek powers to lay mains; Urban District Council of Colwyn Bay and Colwyn; Newmarket Electric Light Company; County of London and Brush Provincial Electric Lighting Company, for powers within the district of St. Saviour's District Board of Works, the parish of St. Mary (Newington), the parish of St. Giles (Camberwell), and the parish of St. Mary (Battersea); Merthyr Tydfil, J. C. Howell, Limited; Liverpool District Lighting Company, for powers within the districts of Allerton, Woolton, Childwall, and Garston; Kettering Urban District Council; Windermere and District Electricity Supply Company, for powers within the district of the Ambleside Urban District Council; Gloucester Corporation; Margate Corporation; County of London and Brush Provincial Electric Lighting Company, for powers within the county of the city of Lincoln; Urban District Council of Sale, in the county of Chester; London and Brush Provincial Electric Lighting Company, Limited, for powers within the borough of Ipswich; Bedford Electric Light Company, Limited, seek powers to produce and supply electricity for lighting and other purposes within the parishes of Great Berkhamsted and Northchurch, Hertford; Folkestone Corporation; Liverpool District Lighting Company, Limited, seek powers to supply electricity for lighting and other purposes within the districts of Great Crosby and Waterloo-with-Seaforth, Lancaster; Bangor Corporation; British Insulated Wire Company, Limited, Prescot, powers within the district of Huyton-with-Roby, also parishes of Whiston, Rainhill, and Eccleston; Darlington Corporation, purchase of land for electric light works.

The following seek powers to construct tramways or railways to be worked electrically—viz., Baker-street and Waterloo Railway Company, with electricity or cable power; London County Council, animal or electrical power; Portsmouth Street Tramways Company; South-Eastern Metropolitan Tramways Company; Kidderminster and Stourport Electric Tramway, powers to incorporate a company, to construct tramways, and work same with electrical or mechanical motive power; London United Tramways, Limited; County of London and Brush Provincial Electric Lighting Company, Limited, powers to construct tramways within the city and county of Lincoln; Sheffield Corporation; Huddersfield Corporation, powers to construct tramways in the borough to be worked by steam, animal, electricity, or other power; Blackpool and Fleetwood Tramroads, powers to incorporate a company to construct tramways and other works in the county of Lancaster, to be worked electrically or otherwise; Blackpool Corporation, powers to construct tramways in the parish of Bispham and to work them by electricity or other means; Derby and Ashbourne Tramways, powers to incorporate a company to construct tramways from Derby to Ashbourne and work same by electrical or other motive power; Sheffield District and Rotherham Tramways, powers to incorporate a company for the purpose of constructing and acquiring tramways and to work such tramways by electrical or other power; Oldham, Ashton-under-Lyne, Hyde, and District Electric Tramways, powers to incorporate a company for the purpose of constructing street tramways in the borough of Ashton-under-Lyne; Sheffield Corporation, powers as to construction, leasing, etc., of tramways and working them by electrical or other power; Swansea Corporation, powers to purchase the undertaking of Swansea Tramways and Improvement Company, and to erect generating stations for working trams by electricity; Halifax and District Tramways, powers to incorporate a company for purpose of constructing tramways and working them by electricity or other power; Brighton and Rottingdean Seashore Electric Tramroad Company, extension of time to complete works, etc.

WATCHES.

With the rapid developments of electrical enterprise, especially with regard to traction work to be expected in the near future, may also be expected a corresponding increased demand on the part of the public for reliable non-magnetisable watches. Many have been the complaints with regard to watches from the various localities in which electric railways have already been installed; but all this would soon be stopped if the public, when in need of new watches, took care to provide themselves with non-magnetisable ones. Messrs. S. Smith and Sons, 9, Strand, W.C., have made the manufacture of such watches a speciality, and are now producing them in great variety, differing in no wise, as far as external appearances go, to ordinary watches. Messrs. Smith and Sons, by the use of an alloy of palladium for the parts hitherto of steel, have been able to produce a non-magnetisable watch which has obtained the highest, or Class "A," certificate at Kew. Watches made by the same firm have also successfully passed through a severe test at the hands of the Admiralty. Another of Messrs. Smith and Sons' specialities is the split-seconds chronograph, with 60-minute recorder, of which they are the sole makers.

This chrongraph, which we illustrate herewith, has been specially designed for the use of electricians, engineers, cyclists, and others, and is also non-magnetisable. It will be found extremely useful by electrical engineers, to whom a reliable non-magnetic watch is an indispensable adjunct. Besides the manufacture of watches, the above firm do a large business in the conversion of ordinary watches into non-magnetisable ones, which, as will readily be understood from what has already been said, is a comparatively easy matter.

WHAT, WHEN, AND WHERE.

Institution of Junior Engineers.

December 6, 8 p.m.—At the Westminster Palace Hotel. Paper on "Considerations with respect to Water, Gas, and Electric Mains, etc, in Connection with the Formation of Urban Roads and Footways," by J. Julian, of the borough engineer's office, Cambridge.

Society of Arts.

December 2, 9, and 16, 8 p.m.—Three Cantor lectures on "Mechanical Road Carriages," by W. Worby Beaumont.

Digitized by Google

INSTITUTION OF ELECTRICAL ENGINEERS, Nov. 28.

MR. R. E. B. CROMPTON (President) in the chair.

At last night's meeting of the Institution the following paper was read:

THE ELECTRIC WIRING QUESTION.

BY FRED. BATHURST, ASSOCIATE.

The "electric wiring question," which is the subject I venture to bring before you to-night, is one in which each individual member of the electrical profession has directly or indirectly more than a momentary interest. Moreover, in view of the contemplated issue of a new set of "wiring rules" which will bear the imprimatur of this Institution, it is at the present moment worthy of careful consideration. With the information and experience which has been accumulated in the past 12 years, we should now be in a position to lay down rules which will advance the art of wiring towards perfection. Such rules should not only conserve the welfare of the public, but should also regard the interests of the electrical industry. My object is to ask that, in any consideration of this question, due recognition may be given to the use of an insulating tube as one of the factors which must enter into the question of perfect wiring. Hitherto the ordinances issued in respect to wiring have had for their primary object the prevention of fire, and have therefore received the general designation of "fire rules." These rules have been rigorously administered under capable, indefatigable, and impartial inspectors connected with the various fire insurance offices. No question can be made as to their efficacy in respect to the prevention of fire, but I submit that, considered from a technical and economical standpoint, they cannot in any way be regarded as ultimate or final. It could be argued with much reason that, from the fact of their having specified definite means and methods under which wiring should be effected, we have even been led to expend our energies in directions which do not truly advance us towards the goal we seek. Electricity, in respect to its utilisation, should not be tied down to specified lines and methods which hamper its proper development and progress.

THE DEVELOPMENT AND GROWTH OF WIRING.

The electric light, from sheer force of merit, has forced its way into recognition as a luxury, and the public now willingly admit that it is an accessory to their comfort and convenience. Perhaps I may be pardoned a momentary digression to outline briefly the electrical progress of England as compared with some other country. Let us take the country typical of progress—America (see Appendix A). Both countries were in 1881 on the same basis; the apparatus was crude, experimental, and imperfect, and the knowledge in respect to the safe and proper handling of the apparatus employed was limited, and possessed by but few people. In England in 1883 the possible dangers began to attract attention, and rules and regulations were issued which were to control development and progress. In America no regulations were enforced; for good or evil, a normal development held its course. The American knew his imperfection, but his utilitarian instinct forced him to employ any means at hand by which to gain further experience. Oftentimes absolute security may have been sacrificed to the necessity of the moment. The American public, however, demanded the new light, and it had to be installed at prices which did not always provide for solidity and permanence. That it was sufficiently satisfactory for acceptance cannot be questioned, since in 1887 they had in operation (not to mention innumerable isolated plants) some 70 central stations, supplying over a quarter of a million incandescent lamps. In England at this time there was one central station, supplying about 5,000 lamps, and a proportionate number of independent plants.

It is just here that insurance authorities may ask about electrically-caused fires. If so, I seize the opportunity for removing what appears to be a greatly exaggerated apprehension. The hurriedly installed apparatus did cause fires, and in a measure terrorised the public much in the same way as our recent subway explosions in London alarmed the British public. Gradually, also, the American fire insurance offices took alarm, and "rules" began to see light. Different States had different regulations, and each inspector became a "law unto himself." Ultimately, it was seen that "confusion had become worse confused," and that effort must be made to produce rules which would be generally acceptable. Within the last few years the underwriters determined to appoint an electrical bureau to collect information concerning the fires said to be "caused by electricity," in order that some general deductions could be made. The reports issued by the bureau (under the effective direction of Mr. W. H. Merill, jun.) are most comprehensive, and give valuable and instructive information in respect to the electrical fire hazard. Taking 1893-1894 as two typical years in which public alarm was prevalent in America, reference to the records shows the occurrence yearly of between 400 and 500 fires traced to electrical causes. Some 320 involve no monetary loss, but the remainder (100 to 200) result in a loss of £300,000 per year. This sum, though apparently large in itself, is less than 1 per cent. of the total fire loss of some £35,000,000 from all causes. The bulk of the electrical loss occurs in the Western States, and for the more populous eastern towns the proportionate loss is less than ½ per cent. The loss arising from the use of kerosene oil and matches is appalling in comparison, and the figures are best not quoted. In fact, the insignificance of the danger from commercial electrical application is best shown by comparison with the loss caused by Nature's wayward electrical illumination—lightning. Taking the figures from the United States Government records, I find, from the average monetary loss per year, for nine years ending 1893, that "lightning" involves a loss of £310,000, or some £10,000 per year more than that caused by the commercial use of electricity. It can therefore, I think, be affirmed that in the country where electrical progress has been least restrained by artificial regulation, the loss on account of the electrical fire hazard is not so formidable as usually supposed. At the present time America has the benefit of numberless motor applications, and over 8,000,000 arc and incandescent lamps, against, perhaps, 2,500,000 in England. Can I not, therefore, argue that restrictions of one sort or another have hampered the proper development of our electrical industry? And, again, is it not a matter of everyday comment with us that the electrical profession, working under the present conditions, does not reap to the full extent the benefit which should accrue to its work?

Returning to our retrospect, we find, however, that, technically considered, we are no longer in the same position as in 1881. Electrical apparatus in every detail has been the subject of patient improvement. Switches have developed from flimsy, poorly-designed mechanisms on wooden bases to substantial metal and earthenware constructions, which are fireproof, and electrically and mechanically perfect. Lampholders, once three-prong wooden devices, fitted with spiral spring contacts, have developed to the present finished type. The insulation on the wires has changed from paraffined cotton to a durable rubber covering. Not only has the quality of material been enhanced many times, but with it market values have fallen so as to be on something like a permanent basis. Central supply stations have been built, and methods of generation and distribution so improved that electricity can be supplied, light for light, at prices directly comparable with gas. Up to the consumer's premises we have economical electrical production and distribution, and, notwithstanding the expense of the initial installation within the house, a demand for the light has grown. The recent rapid growth of municipally-owned electric supply stations would even prove that it is becoming an actual necessity. Why, then, is it that in England, the most prosperous country of the world, this light—the safest and best illuminant—is not making the same rapid headway and progress that it is doing amongst less favoured nations? This, in fact, is the "burning question," which I shall endeavour to make as important as that "question of burning" of the fire insurance companies. Even if it is contended that we are, as a whole, making sufficiently rapid commercial progress, no one will dispute the statement that, commercially considered, the state of affairs with our "wiring contractors" is, to say the least, bitterly disappointing. The bare mention of the fact that for the same piece of work tenders may be received which vary in respect to one another by 100, 200, or even 300 per cent., is in itself sufficient to show the conditions obtaining in this direction.

THE PRESENT PROBLEM.

The principal obstacle to the general use of electrical applications is that under our present wiring rules it is impossible to place the cost of installation within reach of the great bulk of our people. The largest number of consumers to whom we cater—the middle class—cannot afford the initial outlay necessitated by adherence to our present methods. The introduction of electric lighting has educated them to the point of desiring better and more light, but we still have a further duty to perform in bringing this advantage within their means. I submit, therefore, that what is still required is the introduction of rules and regulations which will facilitate the growth of "lower cost wiring." If the term "cheap wiring" is used in this connection, by implication, such work will be termed "nasty." Nothing is further from my intention than to advocate cheap, defective, poor, or dangerous wiring. But, speaking as one whose wish is to promote the welfare of our industry, I suggest that the time has arrived when the advent of "wiring methods" which will reduce the first cost of electrical installation to the general public by perhaps one-half that now obtaining, will, if rightly ordered, give to electrical activity, with its inherent possibilities, that impetus which we all know it to be capable of receiving. With "lower cost" wiring we could, for instance, successfully compete with the lately introduced "incandescent gas burner," which, priced at about 13s., has had a sale amounting to three-quarters of a million. It is being recognised that the ruling factor which governs public demand is small initial outlay. Even the gas companies are facing the question of fitting consumers' premises free, and

Digitized by Google

reimbursing themselves by charging a slightly increased price for the gas supplied.

The Technical Requirements.

Having established the fact that, either from "excess of supply" or a "lack in demand," our contractors are face to face with a serious economic problem, it behoves us to look into our present methods of wiring, to see in which direction economic improvement can be contemplated. Let us consider briefly the essential features of good wiring. The five cardinal points may be given as safety, durability, convenience, accessibility, and economy. Prof. S. P. Thompson, in a lecture on the subject before the Society of Arts, has embodied the essential features in a few words when he said, "What is wanted is a mode of running wires and fixing switches and other accessories so that they shall not only be electric-tight, but shall also be water-tight, gas-tight, air-tight, oil-tight, fire-tight, and even rat-tight." The only "tight" he has omitted is "money-tight." It is my belief that all these requirements can be met by the use of fireproof insulating tubes; but before dealing with this point I may be permitted to challenge the existing methods in the light of these requirements. As the advocates of "concentric wiring methods" are, I understand, to present their views, courtesy leads me to avoid any direct criticism of "concentric" systems, except under those general headings in which they could obviously be included.

Present Methods in the Light of the Requirements.

It will probably be admitted that wood casing fails in many respects. As a "mechanical" protection for the wires it is imperfect, and it is as deficient in "insulating" protection, because it is neither damp-proof nor incombustible. To again quote the words of the above referred to authority, it may also, like charity, "cover a multitude of sins." In concealed work it is positively an obstacle to the development of electric wiring. It shrinks and warps, causing plaster to crack, and often necessitates costly redecoration. The idea of its use originated with the telegraphic engineer, and 15 years ago electricians were contented with it. Then it served the sufficiency of the moment. On account of its one desirable attribute—accessibility—it may survive somewhat longer for surface work. Even on the surface, however, it is neither picturesque nor decorative. It is easy to instal, but its nature prevents any very correct or exact estimate being formed of the labour required. If surface work is required on the score of economy, surely it would be better to adopt "open work" on porcelain insulators—a safe and scientific method of wiring, which can be carried out at a very much lower price. We know this system is discouraged; but it is noteworthy that in the only prominent installation in this country where "open work" has been used, the single source of trouble which occurred arose on a circuit in a damp cellar, where, in order to conform with the fire office "requirements," wood casing had been employed. Someone may argue that this could not have occurred if the circuits had been "tested" as the "rules" recommend. This statement I will answer by a question. It is, whether "insulation resistance" as now specified is not, after all, somewhat of a myth? (see Appendix B). Our "insulation test" never yet told far into the future, and it only tells the present to a limited extent. "Insulation test" cannot discover an unsoldered joint or a dangerous diminution in respect to current-carrying capacity. Every practical man will agree that insulation testing will not necessarily indicate that the wires are at places in dangerous proximity to gas or water systems in event of moisture appearing.

To continue, the recognised shortcoming of wood has brought into use iron and "lead-compo" piping. Lead-compo pipes afford but little mechanical protection in emergency, and, with respect to "accessibility," have serious drawbacks on account of their flexibility. A large amount of "surface leakage" necessarily arises from the use of any ordinary metal tubing. Moreover, if the insulating material on the conductors has from any reason deteriorated and moisture appears, there will be consequent injury both to conductor and tube. Cases have occurred where the protecting fuses on a circuit did not "blow" before electrolysis promoted a dangerous arc which had burnt a hole in the tube and presented a serious fire risk. If a defect occurs anywhere in the insulation of a wire which is within a metal pipe so that there is electrical contact between the conductor and the pipe, the effect of the fault is virtually transmitted throughout the whole length of piping, there to await or invite trouble elsewhere. With two conductors in the pipe a new and unanticipated electrical condition prevails, because one conductor is now of greater carrying capacity than the other, which has been increased by the capacity of the tube itself. Overheating of the intact conductor can now invite serious trouble at any point. This, I think, explains why overloaded wires in pipes have occasionally "burnt out" at several points at the same instant. It must not be forgotten, also, that failure of insulation on one wire means that the voltage tending to break down the other is doubled, and the actual strain (C^2R) increased fourfold.

Perhaps at this point, already, it will be noticed that my criticisms show, incidentally, how much more our immunity from electrical fires has depended upon the honour and integrity of our contractors than upon the "rules" provided for their guidance. Iron pipes have the disadvantages common to all metal pipes, and, as we know, may rust inside, and this rust is not a condition favourable to "insulation"; they often have burrs or other internal roughnesses which may cause serious mechanical damage to the insulating material as the wires are being drawn in. If iron pipes are screwed at the end for the purpose of jointing, oil is probably employed, and any excessive presence inside is not helpful to a rubber insulation. Cases are on record where this oil has caused extensive mischief. Early in the art of wiring it was recognised that gas-brackets, when modified so as to serve as "electrics," should be insulated from the remainder of the gas-piping; but now that we are using electric wires themselves in metallic pipes, we appear to overlook the possibility of the electric system being elsewhere in hazardous contact with conjointly installed steam or water systems. It is now apparent that metal pipes, if not actually harmful, are certainly not particularly helpful to the maintenance of insulation resistance.

As thrifty business men, we must recognise that when buying electric wires we are paying for insulation. It is true we require the copper for current-carrying capacity, but in a high-grade wire the expense of the insulation is about twice that of the copper. From the commercial aspect, apart from any technical considerations, the cost of a metal pipe is a formidable drawback. The usual clause dealing with the protection of "conductors" says "they must be enclosed in substantial wood casing or approved metal tubes." If this refers to iron or compo pipe, and we are to adhere to the regulation, how can we compete with the gasfitter when we have to supply the pipe as well as the insulated wires inside it?

The Advantage of Tube or Conduit Methods.

It may be thought that we must turn away from tube or pipe methods altogether in order to find economic wiring. Experience in other countries, however, does not show that any "rigid" system of conductors is making progress or headway. No insulated wire has yet been produced which in itself can successfully resist the deteriorating influences present in mortar or plaster. Even lead-covered insulating wires, if directly embedded in plaster, have been found wanting, and give trouble from "earths" and "short-circuits" as soon as moisture has made an appearance. With any rigid method, if walls happen to crack and settle, or plasterers and bricklayers cause damage, a fault may develop which is very difficult to find. Usually, also, they are handicapped commercially in respect to making joints and connections, as these involve risk and trouble even with the highest-quality workmen. A cardinal objection to "rigid" methods is the lack of accessibility. All good wiring should be accessible, for with this quality assured half the difficulty of "trouble" is already fought, and any imperfection or injury, whether arising from poor work, negligence, or accident, can be remedied with a minimun of inconvenience. A conduit or race-way is the practical way of rendering wires "accessible," for then the wires installed in them are always open to the inspection of owner or wireman, whenever he wishes to satisfy himself as to their condition or to effect a renewal. "Accessibility" ought, therefore, to be a fire office requirement (see Appendix C); with it an inspector can use his eyes and have no need to trust to his ears for inspection. From the contractor's point of view "accessibility" is desirable as limiting unfair and injurious competition; for when an installation can be readily inspected, inferior materials cannot be used for the purposes of cutting down prices, workmanship cannot be scamped, and the "death knell" of unprincipled competition could be sounded for all time.

The Superiority of an Insulating Tube.

This brings us to the consideration of the conduit itself. From a labour-saving point of view a flexible conduit would apparently commend itself. Whilst cases do occur where this is true, every flexible conduit has the inherent drawback, as shown by experience, that the property of "flexibility" may so far assert itself that numberless bends will prevent the wires from being drawn out. Any trouble which then occurs will have to be cut out, or else the circuit must be abandoned or wired anew. Flexible conduits are always at a disadvantage either in respect to moisture-resisting properties, or are wanting in mechanical strength. Bends and elbows must be rigid, or it is impossible to draw the wires in or out; and for the generality of work it will be found that a conduit construction permanently rigid throughout is preferable. I have already pointed out that more than half of the cost of the wire we use is referable to "insulation," and that it is "insulation" we strive to keep. It would, therefore, appear obvious that the conduit should be an "insulating" one. An ideal insulating tube should not only be mechanically strong, but also fireproof and waterproof.

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE CONFERENCE.

No doubt the late conference will provide texts for many sermons. One clause was warmly debated, and in the end a compromise was made. We refer to Clause 27, which reads that "all conduits, pipes, or casings used as receptacles for electric light lines shall be constructed of durable material and of ample strength to prevent damage from heavy traffic, and when they are laid in streets in which gas-mains are also laid shall be so constructed so as to prevent any influx of gas from the adjacent soil." We shall not recapitulate the discussion to be found reported in another column, but desire to press home strongly the views that must be predominant amongst electrical engineers. No one objects to take all reasonable precautions. They would, in fact, be taken without any Board of Trade regulations at all. The desire of an electrical engineer is to place his wires in street or conduit, and after once placing them to have as little knowledge of their position as possible. Every time his attention is called to his mains it probably means something wrong—annoyance of customers and spending of money. He would be glad to know of some absolutely safe arrangement from faults and troubles. That is—and we have put it very feebly—his position. But what is the position of his partner underground—the distributor of gas? There never has been, so far as we know, any compulsion upon the gas distributor to prevent leakage. From the earliest times of gas distribution to the present it has been known that leakage was more or less constant. It is known that generally the soil around gas-mains is tainted with the leakage from those mains. No particular harm arises while the earth is the receptacle of the leakage — rather the contrary, for up to a certain point such leakage may act as a disinfectant; but if any cavities exist within the area of leakage, into which cavities the gas can penetrate, then the danger of an explosion arises. We may tolerate the stink in the soil, but we cannot tolerate the danger of explosions. Two things seem to be required to obtain the dangerous state—first, the leakage; secondly, the cavity. It would be a monstrous injustice to electrical engineers to compel them to render every cavity gas-tight, when no effort was made to compel gas engineers to render their mains gas-tight. We are inclined to say the latter is by no means a simple operation, while the former is an impossible one under the ordinary conditions that obtain in most large towns. The best possible way out of the difficulty is in the nature of a compromise in which neither party is to be compelled to do the impossible, but that each party is to be compelled to take every precaution, and by constant supervision render an accumulation of gas difficult. We speak under correction, but, according to our knowledge, gas-mains cannot be rendered gas-tight so long as they are made of the material usually employed—viz., cast iron. Similarly, using the ordinary materials for conduits and channels, these cannot be made gas-tight; and so long as there can be a mixture of gas and air, so long there must be the danger of explosion. The simplest and most

Digitized by Google

perfect method of avoiding the danger is by the "freest ventilation." There have been other considerations in the designing of conduits and street boxes than the fear of gas accumulation, and these considerations have undoubtedly played into the hands of gas. Receptacles of the prettiest and most convenient kind imaginable have been made by the score, and the wonder is, not that we have had troubles and explosions, but that we have had so few of them. The weight of evidence seems to point to some "spark" external to the manholes or conduits as usually the immediate cause of the explosion. Yet it must be confessed—and confessed with a considerable amount of shame—that bad workmanship has something to answer for in a few ignitions. You may have explosive mixtures in a cavity till Doomsday without explosion. The exciting cause must be something external to the gases, and, as we hint, an arc has more than once been this cause. Now, an arc at connections can be, and ought to be, avoided. If it exists, the connections are wrong. All this, however, has been said before, and is well known. We are merely trying to emphasise the desire which exists to saddle both parties—the distributors of gas and the distributors of electricity—with precautionary regulations. We thoroughly understand that the major portion of the industry would restrict the stringent regulation to transformer-chambers. We are in the minority, but that only means acquiescence in the views of the majority when the regulation is fixed and irrevocable. The Board of Trade has given full and fair discussion to these proposed revised regulations, and if after they come into force explosions occur at junction-boxes, manholes, or anywhere than transformer-chambers, public opinion will insist upon the most stringent regulations being made, without consulting the wish, the convenience, or the money interests of the profession. What all electrical engineers want is a truer perception of the old adage, "Prevention is better than cure." Too many of them are ready to put up an installation anywhere and anyhow for anything, perfectly indifferent to aught except they get their money for the work done. On every hand, even now, they are promising what they cannot perform, and what every disinterested observer knows must result in failure, instead of insisting that everything should be done in the most perfect manner possible. In our opinion, then, the regulations would better err by being too stringent than by being too lax.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE BOARD'S PROPOSED REGULATION ON TESTING ELECTRIC SUPPLY SYSTEMS.

SIR,—No one could have attended the meeting last week at the Westminster Town Hall on the question of the revision of the Board of Trade regulations for the public supply of electrical energy without admiring the ready way in which Sir Courtenay Boyle accommodated his decisions to those objections of the conference which had been well considered, and to the strict views on each question that Major Cardew's position necessarily obliged him (as the adviser of the Department) to adopt.

On one point I venture to add to my remonstrance made at the time, and to ask you to allow me space in your pages to ventilate my views as to Rule No. 10, which prescribes weekly tests of what is called a "circuit." Eight years ago, when the rules, then drafted in the crudest form, were being considered by a committee of the Institution of Electrical Engineers, I objected to the word "circuit." My fears that it is a misplaced term as applied to systems of electrical distribution under statutory powers, were emphasised on the 19th inst., when Mr. Preece stood up and drew an analogy between the daily testing of telegraph circuits and the testing of electric lighting mains. The word "circuit," if it is rightly applied to such a system as the rules deal with, includes the most remote point with which the sources of supply are connected electrically, which means every conductor and fitting (lamp and electrical) inside the premises of every consumer, as well as the undertaker's mains and service lines under his control, up to the consumer's terminals.

I found it hard to believe my ears, and perhaps I misunderstood what I heard—that it is now proposed to require a weekly test of a whole distribution system, including in the test the wires, etc., in, say, 1,000 houses, and to consider the result thus obtained to have the smallest practical value for purposes of protecting the public or for securing efficient maintenance. I can only conclude that those who believe in it have had no experience, and that Mr. Preece forgot to tell the audience that the Post Office system of daily tests always, if possible, cuts out the loops and sections not maintained by the Department before a test is made.

Any practical engineer knows that one of the chief objects of periodical tests is to obtain a history of the behaviour of the insulation in sections of conductors of such an area as to reduce the labour of localisation should evidence of rapid deterioration or actual breakdown occur. Mr. Preece might just as well propose to his officers to bunch the whole of the circuits entering one large telegraph office in one test, and include in that test every section that might be on the railway company's poles, over the maintenance of which they have no control, and then expect them to arrive at any practical conclusion as to their condition, or as to the works of repair or renewal that is required.

I ventured at the meeting to suggest to the chairman that this most important question required very careful consideration, and that experience since the rules were first issued had grown considerably. My contention is that the condition under which various systems can make useful tests varies considerably. For instance, I believe not many have been laid down and arranged in separate transforming areas before work was commenced, as was the case of the city of London, described in my paper before the Institution in 1893. In such a case the facilities for testing are greater than in systems which began as straggling and pioneer in character, and which have never emancipated themselves from the effects of absence of forethought by those who designed them. I believe that very few undertakers have really carefully considered the best means of excluding their customers' systems from their periodical tests. As time goes on, and insulation deteriorates, it would be forced on them without any Board of Trade rules. Those who have looked ahead and considered it have, I am sure, a happier future before them.

Broadly, I suggest that the question bears an essentially different aspect in the case of those systems which have a large quantity of bare copper conductors and those in which the conductors are insulated throughout.

In my suggestion to the chairman I included one to the effect, that before any rule on the subject is issued the Board of Trade should call on the undertakers of all the well-established systems to report, describing what they have done, and the results, and what it suggests itself to them to do in the future; and this suggestion I am constrained, with your assistance, to press on the notice of the profession as the only way of getting it discussed.—Yours, etc.,

C. E. WEBBER.

THE REVISED REGULATIONS OF THE BOARD OF TRADE.

(Concluded from page 599.)

II.—*Aerial Lines where Erected with the Necessary Consents.*

(16) Every aerial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where this direction is curved, or where the line makes a horizontal angle at the point of support.

(17). Every support of aerial lines shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the lines, or unequal lengths of span. The factor of safety for the lines and suspending wires shall be at least 6 and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow. Every support, if of metal, shall be efficiently connected with earth.

(18) Aerial lines shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by metal binders.

London Chamber of Commerce.—The word "uninsulated" should be inserted before "metal binders."

The amendment of the London Chamber of Commerce to insert "uninsulated" was accepted.

(19) An aerial line shall not in any part thereof be at a less height from the ground than 18ft., or where it crosses a street 30ft. (in the county of London, 35ft.), or within 5ft. measured horizontally or 7ft. measured vertically from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

London County Council.—Eighteen feet, in line 2, should in London be 20ft. to correspond with the London Overhead Wires By-laws.

Barrow-in-Furness Corporation.—Having regard to passage of fire-escapes through streets, and the convenient placing of such escapes against buildings, consider that the minimum height of wires should be 21ft. Consider word "street" indefinite. Think word should be defined or that the clause should read "or where it crosses a street or road."

Dover Co. and County of London Co.—It should be made clear that this regulation does not apply to arc lighting, as in some cases the most efficient means of illuminating narrow streets is by suspension of arc lamps in the middle of the roadway, and the heights given are therefore excessive.

Ogmore Valley Co.—By Board of Trade consent, company are now allowed 20ft. in crossing streets and 2ft. distance from buildings. This suits the district much better than proposed regulation.

Lord Russell asked that the Board of Trade should make the exception desired by the county of London.

The **Chairman** thought it should be 20ft. and 35ft. in London and large boroughs, and 18ft. and 30ft. in special cases. There was nothing in the clause to prevent local authorities from making more stringent limitations.

(20) Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the regulations hereinafter contained as to service lines on the consumer's premises. Every portion of any service line which is outside a building, but is within 7ft. from such building, shall be completely enclosed in stout indiarubber tubing.

London County Council.—The words "and kept enclosed" should be inserted in the last line but one.

Ogmore Valley Co.—Service lines to be enclosed within indiarubber tubing. Qy. necessary where undertakers use such low pressure as this company.

Phœnix Fire Office.—This might be slightly modified. Service lines are sometimes brought into roofs and other inaccessible places. It is most desirable that service lines should be brought into buildings to situations suitable for placing up the main cut-outs and switches in thoroughly safe and accessible places at the points of entrance.

Mr. Heaphy, referring to the amendment of the Phœnix Fire Office, said he had seen service lines brought into roofs and cut-outs placed there where they were almost inaccessible, and hence difficult of access in case of necessity. He strongly objected to the word inaccessible.

The **Chairman** said the Phœnix suggestion should be considered.

(21) When an aerial line crosses a street, the angle between such line and the direction of the street at the place of such crossing shall not be less than 60deg., and the spans shall be as short as possible.

(22) Where an aerial line crosses, or is in proximity to, any metallic substance, precautions shall be taken by the undertakers against the possibility of their line coming into contact with such metallic substance, or of such metallic substance coming into contact with their line by breakage or otherwise.

National Telephone Co.—Desire the addition of a clause providing that where wires carrying high tension currents cross over or under wires belonging to any other person or company, a guard wire must be provided at the expense of the owners of the high-tension wires, for the purpose of preventing the high-tension wires from getting into contact with the wires of such other person or company, and so causing destruction to property.

(23) Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

Institution of Electrical Engineers.—Omit regulation entirely.

London Chamber of Commerce.—Old Clause 32 should be retained. "(32) Where any aerial conductor belonging to the undertakers is erected so as to cross any other aerial conductor or any suspended wire used for purposes other than the supply of energy, precautions shall be taken by the undertakers against the possibility of their conductor coming into contact with such other conductor or wire, or of such other conductor or wire coming into contact with their conductor by breakage or otherwise." This clause should be limited to wires, say above $\frac{1}{16}$.

Mr. Crompton said experience had shown that the clause would be injurious to the industry. Instead of suspending by ligaments, it was safer to make the cables self-supporting. The insulating ligaments were most unreliable, and also deteriorated the insulation of the cables.

The **Chairman** said it was a mechanical question. Suppose the cable broke, and fell.

Mr. Crompton said the tags were the most vulnerable point of the construction. It was always the suspending wire that broke.

Mr. Gunyon, for the London County Council, said he had heard no satisfactory reason for the proposed omission.

Mr. Crompton thought it was obviously better to make the cable self-sustaining, than to carry it by leather tags on a steel suspension wire. It became necessary to insulate the suspending wire, and, in fact, almost every part of such an arrangement defeated its own object.

The **Chairman** of the Taunton Electric Lighting Committee said they had used self-suspending cables of hard-drawn copper, and had suffered no inconvenience. He thought they should not be compelled to alter that.

Mr. Gunyon said a long length of self-sustaining cable might bring a strain on the insulation.

Mr. Crompton remarked that the insulating material was far more extensible than the copper. Mr. Gunyon's point was a purely academic one.

Major-General Webber said the regulation would be disastrous to the conveyance of power. Was it intended that there should be no bare copper overhead conductors used for high-tension currents?

The **Chairman** thought there must be special regulations. He would, however, remark that he had lately come from a large metropolis where there were no aerial lines at all.

Major-General Webber said he was not an advocate for them in towns, but there were many places in the country where the conditions of the clause would compel what was a mere waste of money.

(24) In the case of any aerial line exceeding one-half mile in total length, means shall be provided whereby the pressure may be discharged from any portion of such line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

Institution of Electrical Engineers and Northern Society of Electrical Engineers.—Line 1: after word "any" insert words "high pressure."

This clause passed without debate, the amendment of the Institution of Electrical Engineers to insert "high pressure" in Clause 24 being accepted.

(25) Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with such line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

(26) An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the undertakers intend within a reasonable time again to take it into use.

III.—*Electric Lines other than Aerial Lines.*

(27) All conduits, pipes, or casings used as receptacles for electric lines shall be constructed of durable material

Digitized by Google

and of ample strength to prevent damage from heavy traffic, and where they are laid in streets in which gas-mains are also laid shall be so constructed so as to prevent any influx of gas from the adjacent soil.

Dublin Corporation.—The Corporation boxes are open at the bottom for drainage, and ventilation is provided for in the covers. Neither gas nor water has ever accumulated in them. If the Corporation have to prevent "access of gas" they will have to reconstruct all their boxes, and they doubt if the result would be more efficient.

Dover Co. and County of London Co.—Suggest addition of words "so far as possible" after "so constructed as to prevent."

Yorkshire House-to-House Co —Submit that use of a blower for keeping mains free from gas and water should be considered sufficient, without requiring prevention of influx by a special construction of conduits and boxes.

Islington Vestry.—Object to the requirement as to preventing an influx of gas into conduits. It will seriously increase the responsibility of undertakers, and put a powerful weapon of defence in the hands of gas companies.

Institution of Electrical Engineers.—Substitute for Regulations 27 and 35. "All conduits, pipes, street boxes, or casings used as receptacles for electric lines shall be constructed of durable material, and wherever they are laid under carriageways shall be of ample strength to prevent damage from heavy traffic; and reasonable means shall be taken by the undertakers to prevent accumulation of gas. The undertakers shall regularly inspect their street boxes for the presence of gas, and should any influx or accumulation be discovered, the undertakers are to give immediate notice to the gas authority." That undertakers should only be required to take precautions against accumulation of gas. That risks from explosions caused by influx of gas are very small save under very exceptional circumstances — such as the frost of last winter When so many gas mains are broken, as was then the case, it is impossible to prevent influx of gas to chambers underground. Suggest stricter enforcement of Gas Acts.

London Chamber of Commerce.—Old Clause 14 should be sufficient: "(14) All conduits for conductors constructed in streets in which gas-mains are also laid shall be efficiently protected against an accumulation of gas." Where any influx of gas from adjacent soil occurs to their knowledge, undertakers shall give notice to gas company and to Board of Trade The clause should not be operative in regard to existing conduits, etc. Gas companies should be put under restrictions preventing escape of gas, etc

Glasgow Corporation.—It is impossible so to construct culverts as to prevent an influx of gas. This part of clause should be omitted. Suggest that "all reasonable precautions shall be taken" should be substituted.

Charing Cross and Strand Company.—Appears to be impossible as regards prevention of influx of gas. Ventilation the only practicable remedy.

Portsmouth Corporation and Shoreditch Vestry.—Wish to emphasise as strongly as possible their disagreement. It would be quite impracticable to attempt to render conduits gas-tight. The gas companies should keep their mains gas tight, and the electric light undertakers should be required to ventilate conduits. Gas companies would make this regulation a point of defence for any damage that might accrue through gas leaking into conduits.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—That as gas companies are unable to prevent leakages of gas from their pipes, it is unreasonable to ask electrical undertakers to devise some way of keeping the gas out of their pipes and conduits, and that the only real remedy lies with the gas companies. Suggest that Clauses 27 and 35 be amalgamated, that they should provide that the electric light companies should take every reasonable means to prevent gas entering their pipes or casings, that the companies should subject these to periodical inspections (which might be specified), and that it should be their duty to report at once to the gas company any case in which gas was found to exist, and at the same time either to report to the Board of Trade or the sheriff or local authority if the gas leakage were not found and remedied by the gas company within a reasonable time A regulation such as this could be enforced and carried out, whereas the proposed regulations could not be carried out, and their existence as a dead letter might stand in the way of any reasonable steps being taken

Manchester Corporation.—Between "to" and "prevent" insert "as far as possible" It is practically impossible to construct any subterranean chamber which shall be absolutely gas-tight.

Northern Society of Electrical Engineers.—After "prevent" in line 5, insert "as far as possible."

Mr. Gay, in reference to Clause 27, said he was instructed by the Islington Vestry to press their amendment as hard as the Board of Trade would allow The regulation as it stood would place a very serious responsibilty on the undertakers. The latter used to be required simply to take "efficient measures," but now they were to be compelled to prevent any influx of gas. It might be quite possible by proper ventilation to prevent any serious accumulation of gas, but nearly everyone in the room would agree with him that it was not possible to keep any conduit system absolutely gastight. It might necessitate the expenditure of enormous sums of money if the regulation was made retrospective.

The **Chairman**: Would inserting "so far as possible" be sufficient?

Mr. Gay thought the burden placed upon them was unreasonable. If the gas companies could not keep their mains gas-tight, it was equally impossible for the undertakers to keep their conduits gas tight. The regulation would put a very powerful weapon into the hands of the gas companies, and the electric lighting companies would have to pay for the delinquencies of the gas companies. He (Mr. Gay) contended that electric companies ought not to be hampered on account of the faults of other large bodies, and urged the most serious consideration before the clause was passed.

Mr. Hammond remarked that he had always found it best that the street boxes should have no bottoms, so that all the land drainage could easily get away From his experience in Dublin where they had had no difficulty he should certainly support the amendment of the Institution of Electrical Engineers. It was reasonable to ask them to prevent an accumulation, but not an influx of gas He had filled up boxes with sand or wood blocks, so as to leave no space for accumulation.

Mr. Manville moved the amendment and urged the objections standing in the names of Portsmouth and Shoreditch.

Sir James Russell (Edinburgh) said it was most necessary to impress upon the gas companies that they ought to keep in their gas. At Edinburgh they had two explosions before they had a single dynamo or engine on the place. These were caused by a match, but the papers called them electrical explosions.

The **Chairman** said the Board had sent a circular to the gas companies on the matter

Mr. Crompton thought the true remedy was to insist on notice being given to the gas company as quickly as possible whenever gas was found, and then to put the responsibility on them. In the cases of the supply companies with which he had been concerned, the gas companies had accepted the responsibility and done their best to make good the faults Unless they could get the co-operation of the gas companies and their officials, it would be impossible to get immunity from explosions.

Mr. Morse in reference to the observations of the London Chamber of Commerce, said it seemed very hard to protect gas companies from the results of their actions by imposing regulations on the electrical companies.

Mr. Bayley said that his company had constantly met with gas leakages, and had rendered enormous service to the gas company in enabling them to trace the leakages

Mr. Gunyon, for the London County Council, supported the regulation with the addition of the words "so far as possible." Unless there was some outside pressure put on the companies, they would not get much done. Probably the best thing to do was to fill up the boxes. The gas companies were in possession of the ground, and the gas was in possession of the ground, and that must be considered by any new company coming in.

Prof Kennedy denied strongly that either municipalities or electric companies needed any outside pressure on this point. It had caused them very much trouble He would press seriously that the Board should accept the amendment of the Institution of Electrical Engineers It was a matter which had been very much discussed, and upon which they were practically unanimous.

The **Town Clerk of Hull**, speaking on behalf of the municipal corporations who possessed electric lighting installations, said that those corporations were just as much representatives of the public as the London County Council He must entirely disagree with the doctrine that had just been laid down that those who happened to be first in the field might conduct their operations under the streets in any way they chose without regard to the convenience of others or of those who might come after them.

Mr. Preece said that after 44 years' experience of the fight between electricity and gas pipes they had at last succeeded in getting at what they wanted. In London there were about 16 000 boxes in connection with the Post Office, and it was very rare for a year to pass without some explosions. They did not, however, get into the papers, and not much was heard about them. Where they had left the bottom of the box open, there had been trouble. They had been compelled to seal the bottom up, and in spite of all they could do they still had influx of gas. It was most difficult to prevent it, and he would therefore support the proposition made by Mr. Crompton on behalf of the Institution of Electrical Engineers. They could do no more than take all reasonable precautions. There was, however, a difference between keeping gas out of the small boxes of the Post Office and out of the large transformer boxes of the electric lighting industry.

The **Chairman** said what the Board would like to see was the gas companies obliged to keep their gas in and the electric companies obliged to keep it out. As it was impossible to make that absolute, he should be prepared to recommend the Board of Trade to accept the altered clause proposed by the Institution of Electrical Engineers or something equivalent. He would like it to be "to take reasonable precautions against influx," but he would not press that, and would adopt "accumulations," but with this exception—namely, that it must be made to apply to the conduits for electric lines, and that they must have some more protection when it came to street boxes The Board of Trade had only allowed transformers to be placed in street boxes subject to certain precautions The matter would affect the retention of the figures in Clause 45 when that came on to be discussed.

Prof Ayrton thought what had been said by the chairman would give satisfaction.

The meeting was then adjourned to the following day.

On resuming on Wednesday morning, before proceeding to Clause 28:

The **Chairman** said that he had carefully considered the very important representations which had been made to him on the

Digitized by Google

previous day on the subject of the definition of what constituted a low pressure. The importance of that definition had been brought very clearly to his mind, but the points raised were highly technical and highly scientific, and he did not feel that he could give definite and final advice to the Board of Trade on what had been submitted with regard to the question. He thought, therefore, that it would be most convenient if the decision were reserved and the Board appointed a small expert committee—not exceeding three members—to consider the question and make a final suggestion to the Board of Trade.

(28) Where any electric line crosses or is in proximity to any metallic substance, special precautions shall be taken by the undertakers against the possibility of any electrical discharge to the metallic substance from their line or from any metal conduit, pipe, or casing enclosing their line.

Bournemouth Co.—Is the precaution to be in the nature of insulating from or connecting to the metallic substance? Connecting is likely to be far more permanent than insulating, but is more likely to cause telephone disturbance. Does not the continuous enclosing metallic pipe or casing, cross-connected at all boxes, etc, form a sufficient safeguard, especially if measures are taken to prevent metallic contact?

British Insulated Wire Co.—Suppose that the fact that a conductor has a metallic sheathing connected to earth will render unnecessary any special precautions under the circumstances mentioned.

Dublin Corporation.—Do not see necessity of this, as a continuously earthed iron conduit should be sufficient.

(29) All metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth; and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

Bolton Corporation.—That they have a large number of boxes and pipes which will require alteration to comply with the regulation. Submit that as all their high-pressure wires are concentric and armoured, with the armouring connected to earth, and the outer conductor also connected to earth, there is no necessity to connect across all the cast-iron pipes containing them.

British Insulated Wire Co.—Ask if regulation applies to cases in which concentric cables are used with the outer connected to earth and served over all with a leaden sheathing.

Cardiff Corporation.—That Clauses 29 and 30 appear to clash—*i.e.*, "All metal conduits . . . throughout their whole length" *v.* "Where isolated lengths, etc." Pressure clause refers only to a high-pressure system. This should be made clear.

Blackburn Corporation.—Second part—This has never been the practice on low-tension systems, and to enforce it, which is of no advantage, would cause great trouble and expense.

Institution of Electrical Engineers.—Line 2: after word "any" insert words "high pressure." Add at end of regulation, "except in the case of concentric cables where the outer conductor is efficiently connected to earth."

London Chamber of Commerce.—The word "casings" is ambiguous in this and other clauses. The second part of clause should not apply to concentric cables the outer conductor of which is earthed.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation Oldham Corporation, Sunderland Corporation.—Hope that clause, if retained, will be reworded. It is not clear at present. The phrase "good electrical connection" is employed in a very unusual sense.

Manchester Corporation.—Insert "high pressure" between "any" and "electric line." Or omit regulation entirely, it being unnecessary for so low a pressure as 400 volts.

Northern Society of Electrical Engineers.—Line 2: after "any" insert "high pressure." Add at end of clause, "except in the case of concentric cables where the outer conductor is efficiently connected to earth"

In reference to Clause 29 and the preceding clause and the observations on them, **Major Cardew** said that both clauses ought to stand. What should be done was that the electric lines should be enclosed in some protection of their own, or that there should be some kind of insulation between them and other people's pipes. He would, however, consider the points raised on the observations.

(30) Where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, there shall be interposed between such electric line and the conduit, pipe, or casing such additional insulating material as will prevent the possibility of any electrical charging thereof.

British Insulated Wire Co.—Ask if regulation applies to cases in which concentric cables are used with the outer connected to earth and served over all with a leaden sheathing.

Cardiff Corporation.—Clause appears to clash with Clause 29—*i.e.*, "All metal conduits . . . throughout their whole length," *v.* "Where isolated lengths, etc." Presume clause refers only to a high-pressure system. This should be made clear.

Manchester Corporation.—Alter to read "Where isolated lengths of conduit, pipes, or casing are used for the protection of any high-pressure electric line at road crossings or similar positions, the said conduit, pipes, or casing shall be efficiently connected to earth." Or, insert "high pressure" between "any" and "electric line."

Institution of Electrical Engineers.—Line 2: after word "any" insert words "high pressure." Line 5: omit word "additional." Line 6: for "the possibility of" read "as far as possible." At end of regulation add "but this regulation does not apply to concentric cables with the outer conductor connected to earth."

Westminster Co, Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation—See remarks by same bodies on Regulation 29.

Northern Society of Electrical Engineers.—Alter to read as suggested by Manchester Corporation.

In reference to the proposal of the Manchester Corporation, the **Chairman** said it was affected by any modification they might make in the definition of high pressure.

Prof. Kennedy suggested the case of a cable laid in Doulton casing when an armoured cable went across the road.

Major Cardew thought that the wording of the clause should be "special precautions shall be taken," and it should be left to the undertakers to make them sufficient.

The **Chairman**: If it is altered to "special precautions shall be taken to prevent charging," that will be sufficient.

(31) Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be securely fixed in position, and no unfixed material of a conducting nature shall be contained in the conduit. Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any access of moisture to the conductors or the insulators; and the latter shall be so disposed that they can be readily inspected.

National Electric Supply Co.—Experience shows that with the company's system of mains, inspection of insulators is practically unnecessary, no incrustation having been found.

London County Council—The condition as to ready inspection would apparently prohibit the use of such conduits as those used by the St. James and Pall Mall Company and the St. Pancras Vestry.

Notting Hill Co.—That the prevention of access of moisture to conductors or insulators is impossible, in view of the requirement that boxes should be ventilated.

Institution of Electrical Engineers.—Line 3: for "securely fixed" read "secured" Line 4: after word "unfixed," insert word "uninsulated." Line 8: after word "any" insert word "dangerous." Omit "and the latter shall be so disposed that they can be readily inspected"

London Chamber of Commerce.—The word "undue" should be inserted before the word "access" in line 8

Glasgow Corporation.—Line 3: words "shall be securely fixed in position" should be more definite. Copper strip in Glasgow is not wedged in the insulators, but is free to expand. Clause should be altered to allow this. Suggest words, after word "position," "copper strip in insulators held in position by the force of gravity shall be deemed securely fixed." Last two lines. It is impossible to inspect such culverts as are used in Glasgow. Suggest as an alternative, "that any length of culvert can be disconnected from the system for the purpose of testing."

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—Understand that "securely fixed in position" means "not loose." Hope it may be reworded so as to make it clear that actual fixture in the sense of fastening is not intended.

Manchester Corporation.—Omit "and the latter shall be so disposed that they can be readily inspected."

Northern Society of Electrical Engineers.—Paragraph 2, line 3: after "any" insert "considerable" Paragraph 2, line 4: between "and" and "the" insert "as far as possible."

The **Chairman** accepted the suggestion to alter "securely fixed" to "secured."

Mr. Crompton said the last four words imposed an impossible condition on many existing systems

Major Cardew said it was desirable that the insulators should be inspected in case of deposits occurring

Prof. Kennedy said he had had the pleasure of a talk with Major Cardew on the subject, and he understood that what was meant was that a length should be able to be drawn out, or that by looking through the conduit with a light it could be seen if anything was wrong.

Major Cardew said that the Board of Trade must have some way of seeing whether there was a dangerous deposit.

Mr. Baynes said many of the mains at St. Pancras were too deep for this, and would have to be rearranged. They had something like £40,000 invested in these mains, and the rearrangements would be very costly. He had had the mains opened out for examination in many cases, and had been surprised to find them so clean. It was only at the straining bars that the troublesome deposits occurred.

In reply to **Mr. Wordingham**, the **Chairman** said that it would be sufficient to make the regulation prospective only, and in reference to a remark of **Mr Arnold**, of Gloucester, in reference to leaving the copper free to expand when it rested on the insulators, he remarked that the alteration made in the clause would cover that point.

(32) Any portions of any high-pressure electric lines placed above the service of the ground, or in any subway,

Digitized by Google

shall be completely enclosed either in a highly glazed porcelain tube embedded in brickwork, masonry, or cement concrete; or in strong metal casing efficiently connected with earth, and so protected and guarded as to prevent accidental contact with the casing.

British Insulated Wire Co.—Ask if the regulation applies in cases in which concentric cables are used with the outer connected to earth and served all over with a leaden sheathing.

Halifax Corporation.—"Service of the ground" should be "surface of the ground."

House-to-House Co.—"Service" should read "surface"

Institution of Electrical Engineers.—Line 2: "service" should read "surface." Line 3: after "subway" insert "not in the sole occupation of the undertakers."

London Chamber of Commerce.—The words "or similar material" should be added after "tube" in line 4; the words "and so protected and guarded as to prevent accidental contact with casing" should be omitted.

Charing Cross and Strand Co.—Line 2: "service" should be "surface." In this clause and following "strong metal casing" doubtless covers or should cover lead covered armoured cables.

Northern Society of Electrical Engineers.—"Service" should read "surface." Omit "and so protected and guarded as to prevent accidental contact with the casing."

The misprint of "service" for "surface" having been corrected, the **Chairman** accepted the addition proposed by the Institution of Electrical Engineers.

After some further conversation on the proper wording of the clause, the **Chairman** suggested that "cement, etc.," might be left out, and after the word "and" "it shall be" inserted.

Major-General Webber wanted to know if insulated copper was to be still further insulated.

Major Cardew said there should be some further protection to the metallic casing to prevent people being brought into accidental contact with it. If high-pressure leads were brought up inside a post, the leads should be enclosed in a metallic casing, the casing being so arranged that it could not be touched.

Major-General Webber said if the casing was earthed there was no danger.

Mr. Gay suggested the case of a street lamp-pole. It was impossible to insulate that. Would a steel armouring on the cable be sufficient inside a lamp-post?

Major Cardew considered steel armouring would apply to that case.

Mr. Sayers asked that the regulation might at least be made retrospective. In the case of arc lamp connection the double metallic casing would be awkward.

Major Cardew said insulation was required only in order that the metallic casing should be protected so that it could not be touched.

Mr. Sayers: Would a wood casing apply?

Major Cardew: Yes. Where high-pressure lines were included in a casing connected with earth, it was desirable not to allow people to touch it.

Mr. Lewis (Wolverhampton) suggested that in lamp column work it would be impracticable to take cables protected with steel sheathing into the carriers.

Major Cardew said he had been convinced, and would suggest the omission of the last words from "and" to "casing."

Prof Kennedy said the regulation would compel them to enclose lines going up a lamp-post with a "glazed porcelain tube" or a "strong metallic casing."

Major Cardew said that with the alteration proposed the lamp-post was the casing.

Major-General Webber said the circumstances of lamp-posts and subways were different, and there should be two rules.

Mr. Morse suggested the insertion of "or of some similar material" after the word "tube," rather than the specifying of one particular class of goods.

Major Cardew said he quite appreciated the object of the London Chamber of Commerce in making the suggestion. Would not "highly insulating tube" do?

Mr. Morse preferred "highly-insulating material."

The **Chairman** agreed to this, and in answer to **Mr. Baynes**, said the clause would be retrospective. The amended clause therefore reads: "Any portions of any high-pressure electric lines placed above the surface of the ground, or in any subway, shall be completely enclosed either in a highly insulating material, embedded in brickwork, masonry, or concrete, or in strong metal casing efficiently connected with earth."

(33) Every high-pressure electric line transmitting more than 50,000 watts, or used for the supply of energy to transformers placed in street boxes, shall, except within the generating station, be entirely enclosed in strong metal casing efficiently connected with earth, and such casing shall not contain any low-pressure electric line.

Bournemouth Co.—Regulation will be difficult to carry out, and yet leave the lines accessible for jointing, testing, and repairing, in street boxes, unless a continuous lead-foil coating earthed be taken as a compliance.

Institution of Electrical Engineers.—For Regulations 33 and 34 substitute the following: "Every high-pressure electric line transmitting more than 50,000 watts shall, except within the generating station or sub-station, be entirely enclosed in strong metal casing efficiently connected with earth, or in stoneware or other suitable casing, and such casing shall not contain any low-pressure electric line unless this line is a concentric cable with the outer conductor earthed."

Northern Society of Electrical Engineers.—Add at the end of regulation "unless the main be concentric with the outer conductor earthed."

Chelsea Co.—The provisions of this clause, where Callender-Webber conduits are used, would be inconvenient and costly of application. Experience of the company proves them to be unnecessary.

Portsmouth Corporation and Shoreditch Vestry.—Regulation would materially affect the works of the Portsmouth Corporation. The Corporation are using a highly glazed clay conduit for carrying insulated conductors. The high-tension mains will have in many cases to transmit more than 50,000 watts. The outer conductor is earthed, and therefore any portion of the concentric is only removed from earth by the metallic resistance of the outer conductor, and it is doubtful whether any metallic casing would have a lower resistance to "earth" than is provided in the conductor itself.

(34) High-pressure electric lines not intended to transmit more than 50,000 watts may be enclosed either as provided in the preceding regulation, or in glazed stoneware casings properly laid and jointed in cement at a depth of not less than 2ft. below the surface of the ground and sufficiently protected against breakage.

Institution of Electrical Engineers.—See observation on Regulation 33.

Northern Society of Electrical Engineers.—Omit regulation entirely.

Chelsea Co.—Unnecessary. If glazed stoneware is permissible, then Callender-Webber casing should be equally so.

Westminster Co, Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—The effect of this clause would be entirely to prevent the laying of any high-tension lines under footways, for it very seldom happens that there is anything like a depth of 2ft. between the footway and the top of the cellars below.

Mr. Crompton said the amended clause proposed by the Institution of Electrical Engineers had been the result of a long debate by a large committee. He thought it would prove simpler and more workable.

Mr. Hammond was thoroughly in accord with the amended clause. Owing to the feelings of the Board of Trade on the subject, he had been compelled to use iron culverts in high-tension work where he would have himself preferred stoneware. He thought Clauses 33 and 34 should be taken together—[The **Chairman**: We will do that]—and he hoped they would be permitted to use stoneware culverts whatever the load might be. He would also call attention to the stipulation in Clause 34, that where stoneware culverts were used they should be placed at a depth of not less than 2ft. below the surface. That regulation would take away all the advantage of the permission to use stoneware culverts. Stoneware was only possible when the conductors were placed below the pavements, where a depth of 2ft. was never practically possible, since in the course of a length of street they were sure to come on cellars under the pavement. If stoneware culverts were to be permitted, it must be under a less stringent regulation than one that prescribed a depth of 2ft.

Mr. Sayers thought brick boxes should be accepted. It was well known that brick boxes were used, and under the regulation it would be necessary to take the cables through them cased in a "strong metallic casing." That would prevent getting at the cable for inspection, and would make the operation of jointing difficult and tedious. He called attention to the suggestion of a lead-foil coating.

The **Chairman** thought they might go back to No. 8 of the old regulations and cut out 33 and 34 altogether.—The old clause reads as follows: "Where any high-pressure conductor is laid within a less distance than 18in. from any low-pressure conductor, or from the surface of the ground, or where any low-pressure conductor is laid within the above-mentioned distance from any previously laid high-pressure conductor, efficient means shall be taken to render it impossible that the low-pressure conductor or the surface of the ground shall become electrically charged by any leakage from or defect in the high-pressure conductor."

Mr. Crompton said this old regulation would be very generally preferred.

IV.—*Street Boxes.*

(35) All street boxes which contain any vacant space shall be so constructed as to prevent any influx of gas or water either from the adjacent soil or by means of any pipes, and ample provision shall be made by ventilation or otherwise for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking.

Veale and Co.—That it will be difficult to prevent the influx of gas or water from the adjacent soil, etc.

Bournemouth Co.—That no practicable means are known which will absolutely and under all circumstances prevent the influx of gas or water. Danger from sparking is practically nil with concentric cables, especially if the outer conductor is earthed and the cable lead-foiled or armoured.

Dublin Corporation.—It is practically impossible to carry out this regulation as regards prevention of influx of gas or water.

Digitized by Google

It can be got rid of as at present. See observations of Corporation on Regulation 27.

Sheffield Co.—The efficient ventilation of boxes appears to be a difficulty.

London County Council.—If this regulation could be enforced there would be little danger from street boxes, but at present such a result appears to be hopeless.

Cardiff Corporation.—Corporation's boxes are open at the bottom, to facilitate drainage of water. Corporation have at present no regular system of ventilating their pipes other than by the transformer-boxes, which are ventilated by means of pipes carried up against adjoining buildings, and on the arc light circuits by means of the street lamp posts.

Yorkshire House-to-House Co.—Suggest that use of means for keeping mains free from gas and water should be held to be sufficient, without requiring prevention of influx by a special construction of the conduits and boxes.

Islington Vestry.—Object to the requirement as to preventing influx of gas or water. It will seriously increase the responsibility of undertakers

Institution of Electrical Engineers —Omit entirely. See observation on Regulation 27.

London Chamber of Commerce —Omit entirely, or should be made to accord with 27 as altered.

Chelsea Co —Ventilation of street boxes is a very difficult matter, and would appear rather to draw in a supply of gas from surrounding soil Frequent inspection gives greatest security.

Glasgow Corporation.—Impossible to prevent access of gas. Suggest words "that all reasonable precautions shall be taken."

Portsmouth Corporation and Shoreditch Vestry.—Object for same reason as in case of Regulation 27. Provision for preventing accumulation of gas only should be adhered to.

Westminster Co, Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—See remarks of same bodies on Regulation 27.

Manchester Corporation and Northern Society of Electrical Engineers.—Between "to" and "prevent" insert "as far as possible."

In reference to this clause, which had to a certain extent been condemned by anticipation, and what had passed before during the discussion on Clause 27, the **Chairman** said that there must be some additional precautions with regard to street boxes for transformers beyond what was considered sufficient in the altered form of Clause 27. He suggested for discussion: "In the construction of street boxes containing any vacant spaces, reasonable means shall be adopted so far as possible to prevent any influx of gas or water, and reasonable means by means by ventilation shall be adopted to allow of the escape of gas and prevent danger from sparking."

The **Representative** of the Liverpool Electric Supply Company said that would apply to all street boxes, and not to transformer-boxes only.

Major Cardew: That is so.

The **Chairman**: Is it desirable to ventilate all street boxes?

Several Representatives: No, no.

Major-General Webber said that some of the London local authorities had arrived at the conclusion that there were serious reasons against ventilating every box.

Mr. Hammond did not object to the altered clause if it was limited to transformer-boxes.

It was pointed out at this stage that the word street boxes covered very different things—for instance, junction-boxes, house boxes, and transformer-boxes.

Mr. Gay said it would be impossible to make the boxes air-tight without glands. The actual air-space in the ordinary street box was very small, and would not be a serious matter if proper ventilation was provided. The explosion of a box with a loose cover was less serious than one supposed to be perfectly gas-tight and air-tight.

Mr. Shoolbred thought the word "ventilation" was intended to apply to the pit in which the box was placed The practice he had pursued was to fill up the box, and if that was done the box need not be ventilated.

The **Chairman** said that special precautions were necessary for street boxes used for transformers, and suggested as a definition "boxes containing any apparatus."

Mr. Hammond would make it absolutely compulsory in transformer-boxes to prevent the influx of gas or water, and therefore the provision of ventilation must be omitted. The clause should end at the word "pipes."

The **Chairman** said he was convinced by the discussion of the subject at the Board of Trade that if gas or air got in, it should have an opportunity of getting out again. If there was no means of it getting out, there might be a very dangerous explosion.

Mr. Hammond suggested that the matter should be left in the hands of the Board of Trade. All the boxes they were discussing had been approved by Major Cardew.

Mr. Scott mentioned some cases where brick chambers had been cracked by subsidence of the ground. At Hanley the gas-mains were cracked by subsidence owing to the colliery workings underneath, and the pipes for electric cables were found to be full of gas before the cables were put in. Ventilators were fixed and there had been no trouble

Mr. Gunyon thought there should be a special clause for transformer-boxes and large street boxes, since the latter varied from an 8in. cube to 8ft. or 10ft., or more. If the clause were applied to transformers and to boxes of one cubic yard in capacity, there might be a different regulation for other boxes.

Prof. Ayrton thought they should first of all settle the question of transformer-chambers, and whether they should be well ventilated or perfectly gas-tight.

Mr. Gunyon said the size of the box was important, as well as what it contained.

Mr. Crompton said he was ready to agree with Mr. Gunyon's amendment.

Major-General Webber said that the explosion of a large or small box would be about equally dangerous to anyone standing just over it.

Mr. Hammond thought a cubic yard would prove too small a limit for a box containing cables. The dangerous thing was the box containing the transformer. It was a much easier thing to prevent influx of gas into transformer-chambers than into ordinary boxes. It would be most burdensome to apply it to all street boxes.

Major-General Webber said the limit was inconsistent, for they had a much larger space in a large conduit than one cubic yard

Major Cardew pointed out that it was not concentrated at one point in that case.

Prof. Kennedy remarked that on the continuous current system many boxes were made large, so that a man could get into them for the purpose of getting at the cables to move or alter them or get them out. If the box was in communication with the conduit, it was impossible to prevent the influx of gas.

Mr. Spence (Hammersmith) proposed to insert after the word gas, "and street boxes with more than one cubic yard of space shall be properly ventilated." It would be throwing too great a responsibility on the undertakers to compel them to keep gas out of ordinary boxes.

A **Representative** of the Liverpool company asked that the limit should be increased to two cubic yards to meet their case. They had a very large number of boxes, and had been nine or ten years without any trouble occurring.

Mr. Morse asked, from the legal point of view, that care should be taken in the wording of the clause that in reference to the limitation in the space the box should not be taken to include the conduits

The **Chairman** said Clause 35 should apply only to street boxes containing transformers, and should read "In the construction of street boxes containing transformers efficient means should be taken to prevent any influx of gas or water from the adjacent soil, etc." He would consider further whether it was possible to accept Mr. Gunyon's suggestion as to a space limit for other boxes.

Mr. Geipel: It is sometimes the custom to put very small transformers into boxes.

The **Chairman**: I cannot accept that for a moment.

Mr. Patchell, Charing Cross and Strand Electricity Supply Corporation, strongly supported the suggestion from Liverpool, that the limit should be two cubic yards. His company had several boxes of 1½ to 2 cubic yards which had been worked for the last five years, and which they could not ventilate without allowing water to enter.

The **Chairman** said he would consider if the Board would carry out Mr. Gunyon's suggestion.

Some conversation followed as to what was held to constitute the "box." **Mr. Crompton** remarking that they had first the transformer, then the air-tight case which was called the transformer box, then the street box in which this was put, also called the transformer-box. Another word for this was wanted.

The **Chairman** said the word "chamber" was used. He had always insisted that the cavity was the chamber.

Mr. Crompton said what was suggested was that the iron casing around the transformer itself must be made air-tight.

Eventually the regulation was settled as follows: "In the construction of street boxes used as transformer-chambers reasonable means shall be adopted to prevent any influx of gas or water either from the adjacent soil or by means of any pipes, and ample provision shall be made by ventilation or otherwise for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking."

(36) The covers of street boxes shall be properly secured, and shall, where the box contains high-pressure apparatus, be connected to strips of metal laid immediately underneath the adjacent roadway or pavement.

Bolton Corporation.—Submit that, under their present conditions of working, the connection to strips of metal, etc., is unnecessary.

British Insulated Wire Co.—Ask if regulation applies in cases where concentric cables are used, with the outer connected to earth and served over all with a leaden sheathing.

Dublin Corporation.—This does not appear necessary when iron conduits are used, and should be put in more definite terms, giving conditions as to when it is required.

Islington Vestry.—If cables are included in the word "apparatus," they object to the regulation.

Institution of Electrical Engineers.—Line 1: omit "properly secured" and insert "so constructed that they can only be opened by proper appliances." Line 2: after "apparatus" insert "other than cables"

London Chamber of Commerce —The words "other than cables" should be added after "apparatus" in line 2.

Chelsea Co.—Presume this clause is limited to apparatus other than mains

Charing Cross and Strand Co.—"Properly secured" should mean that some special appliance is necessary to open the box, not necessarily a lock and key.

Westminster Co., Edinburgh Corporation, Aberdeen Corpora-

Digitized by Google

tion, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—Understand that "strips of metal" may be a sufficiently broad flange to the frame of the box. Probably the wording can be altered to make the matter clear.

Northern Society of Electrical Engineers.—Alter to read: "The covers of street boxes shall be properly secured, and the cover frames shall, when the boxes contain high-pressure apparatus, be efficiently connected to earth."

Eastbourne Co —Presume that connection to strips of metal, etc., would not be necessary where the box and lid are of iron and in metallic connection with the system of iron conduits

Mr. Crompton moved the amendments of the Institution of Electrical Engineers, and the second of these was accepted so far as concerns concentric cables with the outer earthed.

Mr. Hammond asked if, when the box was iron and the lid had a wide iron flange, these metal strips were a necessity. He considered such an octopus arrangement simply an unnecessary expense.

Mr. Nesbitt pointed out that if the cover were sufficiently connected to earth the arrangement would be perfectly safe.

The **Chairman** said he would consider how to meet the points raised.

(37) The casing of any high-pressure electric lines shall be continued within street boxes.

Bournemouth Co.—Regulation will be difficult to carry out, and yet leave the lines accessible for jointing, testing, and repairing, in street boxes, unless a continuous lead-foil coating earthed be taken as a compliance.

British Insulated Wire Co.—Ask if regulation applies to cases where concentric cables are used with outer connected to earth and served over all with a leaden sheathing.

Dublin Corporation.—Do not see how this is to be carried out if the cables are to be accessible at the boxes. Where the boxes are iron and connected to the pipes it cannot be necessary. In the case of brick or concrete boxes a metal shield along the sides should be sufficient, but free access to the cables must be preserved.

Institution of Electrical Engineers.—This regulation appears to be covered by No. 29.

Chelsea Co.—With Callender-Webber casing, which has been proved to be absolutely successful and free from defect, it would be impossible to carry out the provisions of this regulation.

Charing Cross and Strand Co.—Remarks in Clause 27 apply here.

Dover Co. and County of London Co.—If "street boxes" include "transformer-boxes," words "except transformer-boxes" should be added, as it is impossible to continue the casing of high-pressure lines within transformer-boxes unless lead or other lapping of the cables be held to be of sufficient compliance.

Westminster Co, Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—"This certainly does not explain itself."

Northern Society of Electrical Engineers.—A definition is required for the word "casing."

Major-General Webber said the regulation would make it difficult to draw cables in and out. There were two kinds of casing in use—metallic and non metallic—and they should not be dealt with in the same way. The rule ignored non-conducting casing, and should be revised to meet the actual circumstances. Many ways would suggest themselves to Major Cardew of obviating the results which had led to the rule.

Major Cardew said one of the most dangerous parts of a high-pressure system was where cables crossed in street boxes. If a non conducting casing was used it should be carried across the box. The cables should not be taken across the box in air with probably an extra length coiled up in the box. This had been the cause of a serious breakdown.

Major-General Webber said the old rule entirely covered the case. He would suggest that it should be left to the undertakers to provide that the high-pressure cables should be so protected and separated from the low-pressure cables that the danger arising out of leakage should be obviated.

In reply to **Mr. Gay**, the **Chairman** said the word "casing" included steel armour.

Mr. Sayers wanted to know what would be the use of a street box if they were to be obliged to continue the casing of the cable through it? It was most important to take off the supply for a minimum amount of time when it was necessary to make a joint. The lead-foil casing which he proposed could be easily and quickly taken off and put on again.

Major Cardew said one of the dangers to be guarded against was that arising from minute sparks passing from one cable to another when these were in air.

Ultimately, the **Chairman** said the regulation would be struck out, that the old regulation (No. 15) might be adopted. This old clause reads as follows: "Where any street box contains high-pressure conductors, efficient means shall be taken to render it impossible that the covers or other exposed parts of these boxes or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise; and all street boxes shall be efficiently protected against any accumulation of gas or water, and their covers so secured that they cannot be opened except by means of a special appliance."

V.—*Converting Stations.*

(38) All converting stations, or points in a system of distribution to which a high-pressure supply is given from generating stations, and from which a low-pressure supply is given to consumers, shall be established in suitable places which are in the sole occupation and charge of the undertakers.

London County Council.—Suggest, for Board's consideration, whether some limit of the power to be concentrated in any one station might not be inserted, and also a provision ensuring the presence of an attendant either at all times in important cases, or at stated intervals in less important cases.

Dover Co. and County of London Co.—"Suitable" is likely to lead to repeated references to the Board of Trade. Suggest: "Converting stations shall be established in places which are within the sole occupation and charge of the undertakers, and shall be suitably constructed so as to prevent as far as possible any influx of gas or water from the adjacent soil."

London Chamber of Commerce.—The words "established in suitable places which are" should be omitted.

Chelsea Co.—Presume that a properly constructed chamber, etc., may form part of any other building.

Institution of Electrical Engineers.—Lines 4 and 5: omit "established in suitable places which are"

The word "converting" in the first line having been altered "transforming,"

Mr. Gunyon opposed the amendment of the Institution of Electrical Engineers to omit "suitable places, etc."

Some conversation followed as to the case where the transformers were placed on the consumer's premises and how the undertakers were to be in occupation of a portion of the consumer's premises.

Prof. Ayrton thought it would be impossible for the consumer to hand over a portion of his property to the supplying company. He would not be willing to do that, and, besides, there might be legal difficulties

Mr. Callender asked if a transformer-chamber built above the street would be considered in the occupation of the undertakers; and **Mr. Hammond** wanted to know if the regulation would oblige the companies to rent a corner of a consumer's cellar if a transformer had been placed there.

The **Chairman** said the regulation applied only to transformer stations, and therefore it would not be necessary to do so unless the particular transformer supplied more than one consumer.

Prof. Ayrton remarked that the question then arose as to who was to insure the property.

After some further conversation, the **Chairman** said the best thing to do would be to go back to the old regulation, which had worked very well. This reads: "Transforming stations, or points in a system of distribution to which a high-pressure supply is given from generating stations, and from which a low-pressure supply is given to one or more consumers, and which are not on the consumer's premises, shall be established in suitable places which are in the sole occupation and charge of the undertakers."

VI.—*Consumer's Premises.*

(39) The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon the consumer's premises, being maintained in a safe condition and in all respects fit for supplying energy.

Burnley Corporation.—That "or" in line 2 should be "and." Submit that it should be made clear that the undertakers' responsibility extends only to mains and apparatus belonging to them and under their exclusive control—*i.e.*, service lines and meters—and not to the consumer's own fittings.

(40) In delivering the energy to the consumer's terminals the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

(41) A suitable safety fuse or other automatic disconnector shall be inserted in each service line as close as possible to the point of entry to any consumer's premises, and contained within a suitable locked receptacle of fire-proof construction.

Liverpool Co.—It has not been their practice to mount the safety fuses in a locked receptacle. The fuses are for the safety of the consumer, and it would be inconvenient if access to the fuses were prevented, it being assumed that the key of the receptacle would be held by the undertakers. All the company's service lines are now protected by fuses in street boxes, and company ask that the regulation, if insisted on, may not be retrospective.

Burnley Corporation.—Omit "locked" and insert "securely fastened and sealed."

Huddersfield Corporation.—Suggest that if the case were screwed up and sealed, it would be more advantageous and less inconvenient than a lock and key

British Insulated Wire Co.—Would not a screw cover with the seal of the undertakers on it meet the requirements instead of a lock?

Birmingham Co.—Suggest addition of word "double-pole" between "suitable" and "safety fuse."

London County Council.—A special regulation appears to be required to secure as far as possible that all main fuses installed shall be placed in cases which either by construction or other protection shall be thoroughly watertight. Two fires have recently occurred in London in consequence of water obtaining access from the street to the main fuses in the house.

Walsall Corporation.—Words "or sealed" should be inserted after "locked."

Digitized by Google

Cardiff Corporation.—Their terminal boxes are "sealed," not "locked."

Notting Hill Co.—"Locked" should be "sealed."

Southport Corporation.—For "locked" read "sealed or locked."

Lancaster Corporation.—For "a suitable locked receptacle" read "a suitable receptacle securely fastened and." This would enable the cut-outs to be fastened by screws and sealed with a lead seal, as is usually done.

Blackburn Corporation.—Practice is to "seal," which is more secure than lock and key."

Wolverhampton Corporation.—"Suitable locked receptacle" should read "suitable locked or sealed receptacle."

Institution of Electrical Engineers, London Chamber of Commerce, and Northern Society of Electrical Engineers.—Line 4: after "locked" insert "or sealed."

Manchester Corporation.—Line 4: "locked." Corporation prefer sealing. Good locks are so expensive as to be prohibitive. Also, seals would leave evidence of a box having been tampered with, which a lock would not.

Glasgow Corporation.—Line 4: after "locked" insert "or sealed."

Charing Cross and Strand Co.—Line 4: insert "or sealed"; "sealing" is generally preferable.

Phœnix Fire Office.—We consider undertakers should place up a switch and a cut out on each service line at the point of entry into the premises, so that the current can be entirely switched off At present the main switches in the majority of cases have to be placed up by the consumer, who often finds it impossible to have them fixed in the proper place on account of the manner in which the service lines have been brought in

Eastbourne Co.—The fuses being themselves constructed with an incombustible case and cover, it would be unnecessary to fix them in a locked receptacle of fireproof construction. Company fix them in a locked wooden box with the meter.

On Clause 41, it was suggested from Manchester that a seal was preferable to a lock, since it was known for a certainty if a seal had been tampered with The Liverpool company also desired that the words should be "locked or sealed."

Prof Kennedy asked if the rule meant that the fuse-boxes must be cast iron? If so, it ought not to be retrospective. There were 1,800 wooden fuse-boxes in the consumers' premises in that district (Westminster). They might, however, be lined with asbestos. If the rule did not apply to fuses on the consumers' premises, did it mean there was to be another fuse in the street?

Mr. Heaphy wanted the words to be "at the point of entry," instead of "as close as possible to the point of entry." The consumer ought to be able to turn the current entirely off his house Cut-outs were often found placed more than 4ft. from the point of entry, and the switch 10ft. or 12ft. off, with the meter between the switch and the cut-out.

Mr. Cottam pointed out that the point of entry was often damp and most unsuitable for switches, etc.; also that consumers preferred their main switches in accessible places.

The **Chairman** thought it might stand as close as possible to the point of entry, and on **Mr. Hammond** rising to support Prof Kennedy's plea that the clause should not be retrospective, the **Chairman** remarked that the Board would allow a reasonable time for alterations, but that a fireproof construction was highly necessary.

Mr. Wordingham said at Manchester they had carried wrought-iron service pipes right up to the fuses — the consumer often wanted the main switch to be placed in the shop; and **Mr. Erskine** remarked that the consumer naturally wanted the switch in the house, where he could get at it, and not, say, in a cellar across a yard.

The amendment allowing sealing was accepted.

(42) All low-pressure electric lines and apparatus placed on any consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and no metal forming part of the electric circuit shall be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

Dublin Corporation.—This appears to apply to "wiring" on consumer's premises, which is done by the consumer. It should be placed beyond question whether the regulation applies to all such low-tension work—including switches—as in most cases it is not carried out by the wiring contractors.

Northern Society of Electrical Engineers.—Line 2: after "premises" insert "by the undertakers." Line 6: after the word "lines" insert "under the control of the undertakers."

London Chamber of Commerce.—Same as Northern Society, and the word "undue" should be inserted before the word "access" in line 4.

Manchester Corporation.—After "premises" insert "by the undertakers." After "lines," in line 6, insert "under the control of the undertakers."

The amendment from Dublin was withdrawn and the clause passed.

(43) Where transformers are installed within buildings on consumers' premises, they shall be contained in a fireproof chamber, securely locked, and the high-pressure service lines in highly glazed porcelain tubes bedded in chases cut in brickwork or masonry.

Bournemouth Co.—The requirements of the clause may often be impracticable in execution, especially in small installations. The service cables installed in the manner proposed would be inaccessible for examination or repair. The alternative of "strong metal casing efficiently connected to earth," amply guarantees safety. The regulation would impose unnecessary expenditure and interference with consumers' premises. Agree to fireproof chambers in cases of large consumers; but claim that metallic pipes give greater security than porcelain tubes, on account of the earthed metal shield.

Bolton Corporation.—That previous regulations allowed transformers to be placed in a strong metal casing connected to earth. If they have to provide a fireproof chamber for each transformer, it may be better to place them under the footpaths in an iron box rather than inside the premises.

Huddersfield Corporation.—Where transformers are installed on consumers' premises, would it not be equally safe to run the high-pressure service lines in a metal pipe connected to earth? Submit that earthenware pipes are not so strong as metal, and are much more costly to fix.

Dublin Corporation.—Too stringent. All high-pressure cables are contained in iron pipes until inside the transformer-chamber, and this is sufficient protection, as access to the chamber is only had by qualified members of the staff.

Halifax Corporation—Old Regulation 18, which allows the high-pressure service line to be placed in metal casing, appears to be preferable. Wrought-iron pipe for high pressure is preferable to glazed porcelain, as it affords a better mechanical protection, it can be used in longer lengths, and the jointing of lengths is more easily carried out. In many cases the wrought-iron pipe can be arranged to screw into the transformer case so as to ensure a complete metallic covering for the high-pressure cable, and also efficient earthing of the transformer case.

Sheffield Co—Assume that the provision of transformers, which are completely enclosed in metal cases with an iron screen between the primary and secondary windings connected to earth, meets the requirements of this regulation.

Dover Electricity Co and County of London Co.—Suggest addition of "or in iron pipes efficiently connected to earth" after "masonry." This has been carried out in many places.

Yorkshire House-to-House Co.—Object to clause, which would cause serious inconvenience and expense. Present regulation meets all reasonable requirements. Use of porcelain tubes for high pressure service lines would involve difficulty in coupling to the street mains, and such tubes would also be difficult to connect to the iron transformer-cases Present practice works satisfactorily—*i e*, to fix transformer in a fireproof cast-iron case, and to carry the cable from the street main to the transformer-case in wrought-iron tubes, which, like the case, are connected to earth.

London Chamber of Commerce.—The words "or sealed" should be inserted after word "locked" in line 3. The words "or other equally effective material" should be inserted after the word "tubes" in line 4.

Northern Society of Electrical Engineers.—Alter to read: "Where transformers are installed within buildings on consumers' premises they shall either be contained in a fireproof chamber, securely locked, or within a metallic receptacle efficiently connected to earth, such receptacle to require the use of a special tool before it can be opened, and in either case every portion of the framework of the transformer shall be efficiently connected to earth. The high-pressure service lines shall be contained either in highly-glazed porcelain tubes bedded in chases cut in brickwork or masonry or in metallic tubes efficiently connected to earth."

Eastbourne Co.—Regulation should be modified to permit the use of metal casing well earthed as in Regulation 32.

Institution of Electrical Engineers.—Line 3: for "chamber" read "case," for "locked" read "fastened." Omit words "highly . . . masonry" and insert "protective tubes or in metal casings connected to earth."

Mr. Shoolbred asked at whose expense were the alterations necessary to comply with this clause to be made, and the **Chairman** said it depended on the particular provisional order.

Mr. Shoolbred thought all companies should be upon the same footing, and the **Chairman** remarked that the question arose when the system was approved by the Board.

Mr. Sayers proposed that Clause 18 of the old regulations should be substituted for the present clause. That had answered perfectly well in the case of small installations of from one to four kilowatts The provision was one which they could not get consumers to agree to. The masonry cover was almost prohibitory. On the other hand, it might be necessary in cases of 10 to 20 kilowatt installations.

Mr. Rider agreed with Mr. Sayers that the cost would be prohibitory.

Mr. Heaphy wanted the clause to stand, but the **Chairman** said the consensus of opinion was in favour of going back to the old regulation as proposed by Mr. Sayers. The clause will therefore read: "Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on the consumers' premises, connected to the distributing mains by high-pressure service lines, and to the consumers' terminals by low-pressure service lines, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself so far as they shall be on the consumers' premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connected to earth, and securely fastened throughout."

(44) If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise,

Digitized by Google

that a connection with the earth exists at some part of a circuit of such resistance as to be a source of danger, and that such connection does not exist at any part of the circuit belonging to the undertakers, then and in such case any officer of the undertakers, duly authorised by them in writing, or, if the undertakers so require, an electric inspector may, for the purpose of discovering whether such connection with the earth exists at any part of a circuit within or upon any consumer's premises, at all reasonable times, after giving one hour's notice of his intention to do so, enter any such premises and disconnect the consumer's wires from the service lines, and may require the consumer to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit. In any case where the undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

Institution of Electrical Engineers, Northern Society of Electrical Engineers, and London Chamber of Commerce.—Add at end of regulation, "and in case the fault be found to exist on the consumer's premises, the undertakers shall be entitled to recover the said fee from the consumer."

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—Hope something may be done to give undertakers more power to repair in the case of defects which they may think may lead to serious accidents.

(45) If on such testing the officer or the electric inspector discovers that a connection exists between the consumer's wires and the earth, and that such connection has an electrical resistance not exceeding 5,000 ohms, or if the consumer does not give all due facilities for such inspection and testing, the undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of such discontinuance to the consumer, and shall not recommence such supply until they are reasonably satisfied that such connection with the earth has been removed. Provided that in cases where the maximum power taken by any consumer exceeds 25,000 watts, the consumer's wires may be divided for the purposes of this testing into separate circuits, the insulation resistance of each of which shall exceed 5,000 ohms.

Bournemouth Co.—Limit of 5,000 ohms is too low, and may be inconsistent with Clause 10. Minimum should be proportionate to size of installation and the current used, as is usual in supply companies' regulations as to tests before connecting, and in fire insurance companies' regulations.

British Insulated Wire Co.—Last paragraph. Think the separate circuits into which large consumers' wires may be divided should be specified.

Sheffield Co.—Consider 5,000 ohms resistance much too low, and calculated to encourage wiring contractors in practices which are detrimental to the interests of supply companies.

London County Council.—5,000 ohms seems to be a very low figure. The minimum resistance might be raised without the slightest hardship in any case to at least 50,000 ohms; or it would probably be better to specify the resistance varying with the number of lamps or other current-consuming devices installed. If this be done, it might be possible to reduce the variation of pressure allowed by Regulation B (7) from 4 per cent to 3 per cent.

Notting Hill Co.—Consider that the insulation resistance of any installation should be on a sliding scale, according to the number of lights, and not to one fixed standard.

Dover Co. and County of London Co.—Installation specified is too low. Suggest minimum of 50 megohms divided by number of 8-c.p. lamps in circuit. The second paragraph does not limit the number of separate circuits.

St. James and Pall Mall Co.—In the latter part of the clause, it is not stated into how many separate circuits a consumer of above 25,000 watts may divide his wires.

Manchester Corporation.—Line 4: 5,000 ohms far lower than should be allowed. Corporation consider 10,000 ohms, the limit fixed by their present regulations, is too low. Board of Trade allowed a minimum of 10,000 ohms in Manchester.

Manchester Corporation.—Alter 5,000 ohms to 100,000. If work is done even moderately well the insulation resistance should exceed 10,000 ohms. Lowering the standard would encourage contractors to carry out bad work, and the Corporation find it difficult even now to enforce their by-laws for wiring on consumers' premises.

Northern Society of Electrical Engineers.—Alter minimum of 5,000 ohms to 20,000.

Institution of Electrical Engineers.—Omit proviso.

(46) If any consumer is dissatisfied with the action of the undertakers either in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of such consumer may, on his application and on payment of the prescribed fee, be tested for the existence of connection with the earth by an electric inspector. This regulation shall be endorsed on every notice given under the provisions of the last preceding regulation.

Institution of Electrical Engineers and London Chamber of Commerce.—Substitute the following regulation: 46. (*a*) If any consumer desires the undertakers to commence the supply, or if he is dissatisfied with their action under the preceding clause, the wires and fittings of such consumer may, on his application, and on payment of the prescribed fee, be tested by an electric inspector, and if the insulation resistance of the consumer's installation is equal to 75 megohms divided by the number of points for taking off current, the undertakers shall make the connection and refund the consumer the fee paid to the electric inspector; (*b*) if the undertakers have reason to believe that an installation already connected to their mains is in a faulty condition, they may test such installation, and if the insulation resistance is found to be less than 75 megohms divided by the number of points for taking off current, the undertakers may discontinue the supply; and in case of difference an electric inspector is to be called in by either party and his fee is to be paid by the party at fault. This regulation shall be endorsed on every notice given under the provisions of the last preceding regulation. Consider it desirable that the position of undertakers in consumers' premises should be clearly defined, as suggested in the regulation submitted.

Northern Society of Electrical Engineers.—Omit entirely.

Mr. Hammond, referring to Clause 45 in connection with Clause 44, wanted the provision made more stringent as if the electrical resistance went down to 5,000 ohms with a number of consumers it would cause great trouble. He would propose that the Board of Trade should lay down rules for wiring.

The **Chairman**: We have never gone into private houses, but have kept carefully outside.

Mr. Hammond remarked that a man might say his leakage did not exceed what the Board of Trade allowed and might insist on being connected. The Phœnix rules provided a scale ranging from 500,000 for 25 lights to 125,000 ohms for 100 lights, and so on. He would suggest that an installation should not be connected if the insulation was less than the number obtained by dividing 75 megohms by the number of lamps.

Prof. Ayrton said there should also be the power of cutting off the consumer when his insulation fell below that point.

Mr. Crompton was in agreement with Mr. Hammond.

Major Cardew said that where the insulation resistance had fallen down to such a despicable figure as 5,000, the undertakers should be compelled to cut off.

Prof. Ayrton said there would be danger of difficulty from bad work in houses, because the householder knew very little about the matter. It should be known that unless the work there was properly done, there was no prospect of being connected on. He would support the amended form of the subsequent clause (46A) standing in the name of the Institution of Electrical Engineers.

The **Chairman** said that the proposed amended clause, 46A and B, only empowered the undertakers to do what they could do already. The *raison d'être* of Clause 45 was to make it compulsory to cut off at a certain figure.

Prof. Ayrton said that was like telling a man he had legal power to arrest a thief. He wanted more than that; he wanted a policeman.

Mr. Morse said the power was not contained in the Chelsea order.

Mr. Wordingham said it was the general feeling among contractors that the consumer could insist on being put on at 10,000 ohms.

Major Cardew suggested that the limit might be a leakage of one thousandth of the current supplied instead of the 5,000 ohms limit.

After further conversation, the **Chairman** said Clause 44 must remain and 45 should be accompanied by words providing that the regulation should not affect any power contained in the provisional order to cut off the supply.

Prof. Ayrton said in the city of London they had asked for a limit of 100 megohms divided by the number of points wired, and had often got it.

Sir James Russell (Edinburgh) said that the general feeling of the public was always to work down to the minimum.

Mr. Sayers thought one-thousandth of the current was too low.

After further conversation, **Prof Ayrton** suggested that the figure should be 75 megohms divided by the number of points of taking off current, but it was objected that this would be too high for motors.

Mr. Gunyon agreed that 75 was too high a number. One difficult light might bring the figure down to that.

The **Chairman** said the form of the regulation would be that the undertakers might, but should not, be compelled to cut off at a certain figure, and that they must cut off below another certain figure.

VII.—*Arc Lighting*

(47) All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

Institution of Electrical Engineers.—Further information desired as to the application and intention of the regulations comprised under Section VII.

Northern Society of Electrical Engineers.—Add "under the control of the undertakers."

Digitized by Google

London Chamber of Commerce.—Add "belonging to and under control of undertakers."

Glasgow Corporation.—The Corporation suggest with respect to Regulations 47, 48, and 49, alterations which the above suggestions would meet.

Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—Understand that this is intended to be limited only to arc lamps, both put up and supplied with current by the undertakers in public streets. Question will arise whether the section would apply where a corporation has put up lamps in the streets, while the lamps are supplied with current by a private company. The corporation would in that case apparently not be acting under the Electric Lighting Acts in putting up the lamp-posts. It is also a question whether section would apply to arc lamps in buildings belonging to corporations who are undertakers. If so, corporation buildings would be under regulations which would not apply to exactly similar buildings which are private property, owing to the corporation supplying current. Suggest omission of section.

Bournemouth Co.—If the clause applies only to lamps which are the property of and are maintained by the undertakers, words are required to so limit its meaning. Undertakers should not be made responsible for construction and maintenance of lamps which may be property of consumer and in no way under undertakers' control, nor should they have to decide as to any danger of the presence of explosive dust or gas in the situations in which lamps are to be used.

Bolton Corporation.—Presume that this only applies to public arc lamps, as the undertakers have no control over private arc lamps.

The *Electrician*.—"Nor is this the only blow which the new proposed regulations may possibly direct against arc lighting. In Section VII., paragraph 47, it is provided that these lamps 'shall not be used in situations where there is any danger of the presence of explosive dust or gas.' The expert above referred to, a man of unsurpassed experience in arc light matters, is inclined to regard this regulation as being too stringent because this danger exists in every building where gas is used. We hardly think, however, that it can be the intention of the Board of Trade to prohibit the use of arcs and gas jets in one and the same building. As well lay down a law that no building shall have two or more gas jets, on the ground that one might be 'escaping' while the others were alight."

Phœnix Fire Office.—Are glad this regulation has been drawn up.

Newcastle Co.—Too stringent. There is always danger of gas leaking wherever fitted in a house. The rule might be construed to mean that where gas is used in a building for lighting, etc., arc lamps must not be erected.

(48) Arc lamps used in any street shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

Edinburgh Corporation.—That the regulation as drawn goes beyond the powers of the general Acts, and would apply to lamps on consumers' premises or outside windows, and such lamps, often, cannot be hung so high as 10ft. Suggest that clause be altered to refer in express terms to arc lamps used for public lighting of streets.

Liverpool Co.—No objection if regulation refers only to public lamps for street-lighting. Point out that, by Liverpool Corporation regulations, consumers' arc lamps can now be fixed at 8ft. from the ground, and that to raise them 2ft. would render them useless for their intended purpose—*i.e.*, lighting shop windows.

Burnley Corporation.—If regulation applies to arc lamps for lighting shop windows, submit that "ten" be altered to "seven" feet, the height allowed for gas lamps. If for street-lighting only, words should be inserted in the regulation to that effect.

Bolton Corporation.—Presume that this applies to public arc lamps only, the undertakers having no control over private arc lamps.

Huddersfield Corporation.—If 10ft. applies to lamps used for lighting shop windows, doorways, etc., it is prohibiting the use for such purposes. Usual height, 7ft. 6in.; 10ft. low enough for street lamps.

Halifax Corporation.—This would prevent the use of arc lamps outside shops with low windows. Suggest that the regulation should apply to high-pressure arcs only.

Walsall Corporation.—10ft. should be 8ft.; the height which gas lamps have to be above the level of the footway by general law; 10ft. would probably prevent shopkeepers using arc lamps outside for lighting their windows.

Southport Corporation.—10ft. should be 8ft.; 10ft. would prevent use of arc lamps for lighting outside shop windows. Local Act provides that no projection, sun-blinds, etc., shall project above footpath at less than 8ft. from the ground, and no inconvenience is caused.

Lancaster Corporation.—It is often useless and impracticable to fix arc lamps more than 7ft. or 8ft. from the ground. Suggest that the regulation apply only to high-pressure arc lamps.

Blackburn Corporation.—Lamps have been fixed at less than 10ft. Tenant on ground floor has no right to fix a bracket higher than his own part of the buildings. Arc lamps properly fixed are as safe as gas lanterns.

Wolverhampton Corporation.—Low-tension circuit arc lamps should be excepted.

Bury Corporation.—Arc lamps erected at a height of 10ft. will not meet the requirements of shopkeepers—the height proposed is too stringent, especially as at Bury the system is low pressure.

The *Electrician*.—"The Board of Trade draft of the new regulations and conditions for the safety of the public in the matter of electric supply, which we reprinted and commented upon in our issue last week, will have the effect, if put into force, of considerably modifying at least one branch of electric lighting—to wit, the use of small arc lamps for lighting shop and other exteriors. No one can have failed to notice the rapid and extensive increase of this class of apparatus, and anyone who has compared the relative economy and convenience of small arcs and large incandescent lamps for shop exteriors will probably have discovered the superior merits of the former. But, as has been pointed out to us by an arc lamp expert all this seems likely to be quashed, and the use of arc lamps in this way "in any street" will become difficult if the 10ft. from the ground rule is to be enforced. It is easy to see why large arc lamps, with bulky globes protected only by wire netting, should be placed beyond the possible thrust of a giant's umbrella; but it is not so easy to comprehend why it is that small arcs placed in suitable metal reflecting cases in front of shop windows should be treated more stringently than gas or oil lamps similarly situated."

St. Pancras Vestry.—Clause prohibits use of arc lamps for shop-window lighting where the arc lamp is too often about 8ft. from ground, just clear of a person walking underneath. In street-lighting, average height of gas column is 8ft.; if small arc lamps are used with these columns the height of the arc would not be more than 9ft.

Manchester Corporation.—After "arc lamps" insert "connected to any high-pressure circuit." The regulation as it now stands would preclude the use of arc lamps in many situations outside shops where they are now fixed.

Edinburgh Corporation.—See remarks of Corporation on Regulation 47.

Eastbourne Corporation.—Regulation applies presumably to high-pressure lamps only under control of undertakers. Low-pressure lamps would be fixed by consumer where he liked.

Eight feet, instead of 10ft., was suggested from Liverpool as the minimum height of arc lamps in the interests of shop-window lighting, and this was supported from Taunton and elsewhere.

The **Chairman** said the working limits should be 10ft. for arc lamps for public lighting and 8ft. for private lights, provided these were screened from contact.

(49) A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide (*a*) that the lamp can by its means be entirely disconnected from the supply circuit; (*b*) that the switch itself can be safely operated in the dark by an inexperienced person and without special precautions; and (*c*) that there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.

Bolton Corporation.—Presume that this applies to public arc lamps only, the undertakers having no control over private arc lamps.

Birmingham Co.—Suggest "double-pole switch."

Wolverhampton Corporation.—(*b*) Omit reference to "inexperienced person," otherwise Board of Trade sanction operating of a high-tension switch by an inexperienced person, which should not be.

St. Pancras Vestry.—Omit words in paragraph (*b*) after word "dark."

Edinburgh Corporation.—Omit "by an inexperienced person."

The words "inexperienced person" were left out of this clause.

Penalties.

(50) If the undertakers make default in complying with any of the preceding regulations, they shall be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10. The imposition of any penalty under this regulation shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of such default.

Greenock Corporation.—That the penalties appear to be excessive.

Northern Society of Electrical Engineers.—Alter £10 to £5, and omit second paragraph.

The **Town Clerk of Hull** called attention to the wording of the clause, which might cause an assumption that the undertakers were liable to make compensation when they should not be, and the **Chairman** said he would consider how to meet the point.

B.—Regulations as to Supply.

(1) One week at least before the undertakers are ready to commence to supply energy through any feeding, charging, or distributing main, they shall serve a notice upon the local authority of their intention to commence such supply.

Notting Hill Co.—Consider that the ordinary notices served on the different authorities of intention to construct new mains should be sufficient intimation of intention to supply energy through such mains, and that to give a further week's notice is unnecessary delay.

Digitized by Google

Chelsea Co.—A delay of one week for notice of intention to supply is much too long. Suggest one clear day's notice.
One week was altered to 48 hours.

(2) From and after the time when the undertakers commence to supply energy through any distributing main, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the undertakers, be constantly maintained. Provided that, for the purposes of testing, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time, and for such periods as it may think expedient, and that for any other purposes connected with the efficient working of the undertaking, the undertakers may, with the permission of the Board of Trade, discontinue the supply at such intervals of time and for such periods as the Board of Trade may think expedient. Where the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

Burton-on-Trent Corporation.—Raise point as to form of regulations. Company *v.* local authority. Mem.—The form of regulations will be adapted to fit case of local authorities who are undertakers.
Dover Co. and County of London Co.—Instead of "as it may think expedient," suggest "as may be necessary."
Newcastle Co.—It seems a loss of time to all concerned having to apply in every instance to the local authority, especially as under Regulation 10 tests have to be made once a week.
The words "or for any other purpose connected with the undertaking" were inserted after "testing."

(3) The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers; and in the case of every stoppage for more than one hour, reasonable notice shall be previously given by the undertakers to every consumer affected thereby except in cases of emergency.

London County Council.—The maximum power of 200,000 watts is rather large, and might in many cases be reduced.
Dover Co. and County of London Co.—Suggest raising of maximum power to 350,000 watts and number of consumers to 100.

(4) During the whole of the period when a supply of energy is required to be maintained by the undertakers in the distributing mains under the order and these regulations, it shall be maintained at a constant pressure (in these regulations termed the "standard pressure") to be fixed as hereinafter specified, but such standard pressure may be different for different portions of the distributing mains. Provided that the undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 3 per cent. from the corresponding standard pressure in the case of a general supply at low pressure, or 2 per cent. in the case of a general supply at high pressure, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

Manchester Corporation and Northern Society of Electrical Engineers.—Lines 12-14: omit "in the case of a general supply at low pressure or 2 per cent. in the case of a general supply at high pressure."
Prof. Ayrton remarked it was not clear why the difference was made between high and low pressure, and **Major Cardew** said the limits were drawn as tightly as they could be worked to. There was not the same difficulty with the high-pressure system, which had transformers, as with the low.

(5) The standard pressure shall be fixed by the undertakers for every pair of distributing mains, and notice of the amount of such standard pressure shall be given to the local authority before the undertakers commence to supply energy to consumers through such mains, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month, in such manner as the local authority may require, of the intention of the undertakers to apply for permission to alter the same. The undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

Northern Society of Electrical Engineers.—Substitute "Board of Trade" for "local authority" in lines 7, 8, and 10.

(6) Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not, except by agreement, be greater than 150 volts or less than 45 volts if continuous, or the equivalents thereof respectively, if alternating, and shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system the central terminal shall for the purposes of this regulation be considered to form a pair with either of the outer terminals, and similarly for multiple-wire systems, and in the case of a transformation of energy on the consumer's premises the undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

London County Council.—After "different pressures" in line 17, words "within the above limits" should be inserted.
Dover Co. and County of London Co.—Instead of 150 volts suggest 220 volts.
Institution of Electrical Engineers.—Lines 6-8: omit "than 150 . . . . if alternating," and insert "if continuous, then 300 volts when for purposes of lighting, or 600 volts for other purposes, and, if alternating, then 250 volts for purposes of lighting or 500 volts for other purposes." Support general desire of the profession to use glow and incandescent lamps taking from 200 to 250 volts at their terminals. Line 14: omit all regulation after word "system."
London Chamber of Commerce.—The words "if continuous, or the equivalents thereof respectively, if alternating," should be omitted. Line 14: omit all regulation after word "systems"
Charing Cross and Strand Co.—150 volts should be increased to 200 volts, as 200-volt lamps are now obtainable.
Westminster Co., Edinburgh Corporation, Aberdeen Corporation, Belfast Corporation, Oldham Corporation, and Sunderland Corporation.—For pressure to be raised to 220 volts, 200-volt lamps being, or likely soon to be, largely in use.
Manchester Corporation.—Alter to read "the pressure so declared at any pair of consumer's terminals shall not, except by agreement, be greater than 500 volts, or less than 45 volts if continuous." It is important that they should be able to declare a pressure of 400 volts in cases where the current is used for the supply of large motors, as if they had to supply at 100 volts serious difficulties would arise.
Northern Society of Electrical Engineers.—Alter 150 volts to 500. Omit all after word "systems" on line 14.

(7) The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, nor at any time exceed, 4 per cent. from the declared constant pressure, whether such variation be due to the resistance of the service lines or apparatus belonging to the undertakers, or to any action or effect produced by such apparatus, for which the consumer cannot be shown to be responsible, or partly to any variation of pressure in the distributing mains from which the supply is taken.

London County Council.—Variation of pressure allowed might be reduced from 4 per cent. to 3 per cent. if suggestion of Council on Regulation 45 be adopted. After "responsible, or" in last line but one, "wholly or" should be inserted.
Institution of Electrical Engineers.—Line 3: omit "nor at any time." Line 3: after "exceed" insert "continuously." Line 4: omit all words after "pressure."
London Chamber of Commerce.—The words "for unreasonable period" should be inserted after word "exceed" in line 3.
Charing Cross and Strand Co.—With a view to preventing a vexatious application of Clause 8 some short period of time might be added, such, for instance, as is necessary for a good engine governor to act when a load is thrown on or off.
Northern Society of Electrical Engineers.—Line 3: omit "nor at any time." Line 3: after "exceed" insert "for any reasonable time."
Clause 6 awaits the decision of the committee as to what is a low pressure, and in Clause 7 "at any time" was omitted, and the whole of the words after "constant pressure."

(8) If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the order, be liable to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

Northern Society of Electrical Engineers.—Alter £5 to 40s.
This passed without observation, as did all the rest.

Digitized by Google

Miscellaneous Observations and Objections.

Coventry Corporation.—That mains have been laid and other work done under present regulations, and that it will be a hardship if more stringent regulations are now to be applied to this work.

Bournemouth Co.—Observe that the regulations do not provide specially for the case of concentric mains, or the earthing of outer conductors of concentric mains, and presume they will be adapted to the system used by different undertakers.

Ayr Corporation —That they have only just received and printed their regulations, and protest against the new ones.

British Insulated Wire Co.—Ask if the new regulations are to be made retrospective, "that is to say, is plant which is already now in position to be used if it does not comply with the then regulations?"

Sheffield Co —Regret that no special privileges have been definitely provided for the removal of the current from the mains for a reasonable period for the purpose of joining up new consumers."

VII.—*Arc Lighting.*

London County Council.—A regulation should be added requiring the leads taken up the lamp-posts to be properly secured by means of insulators in the columns, and also providing that the leads should be insulated with special care, and that the material used shall be of the highest quality for the purpose.

Barrow-in-Furness Corporation.—Assume that the regulations refer only to the supply of electricity for lighting purposes, and not in any way to traction.

Cardiff Corporation.—Ask if the regulations are intended to take effect retrospectively and to apply to existing works If so, they will seriously affect Corporation's lighting scheme and put them to considerable expense. Corporation will be prepared to carry out future works in accordance with new regulations. Ask when regulations are to take effect.

Metropolitan Co.—Observations will be embodied in reply of Institution of Electrical Engineers.

Hastings Corporation —Although compliance with new regulations will necessitate the making of considerable alterations by the local company, Corporation consider the regulations desirable in the interests of the public safety.

City of London Co —Concur in alterations to be submitted by the Institution of Electrical Engineers.

Hove Co.—Concur in views to be put before the Board of Trade by Institution of Electrical Engineers.

Kensington and Knightsbridge Co.—Submit the same observations upon the regulations as the Institution of Electrical Engineers.

London Chamber of Commerce.—A note should be added to the effect that these regulations are only applicable to electric lighting provisional orders as distinguished from electric traction The regulations applicable to low pressure only or high pressure only should be distinguished.

Chelsea Co.—The regulations do not appear to have taken into consideration the peculiar circumstances attaching to the use of a continuous-current transformer system in conjunction with motor-generators and secondary batteries

Institution of Electrical Engineers.—The Council have had brought before them the very important question of the connection to earth of one of the conductors of an electric system. This is distinctly prohibited by the Act except in such cases where permission of Board of Trade has been given. Considerable disappointment has been felt that no mention is made of this subject in the draft regulations under consideration, but it was felt that the subject was a far too important one to be dealt with in the short time which the Council has had at its disposal.

Institution of Electrical Engineers.—That one effect of the new regulations will be to introduce automatic cut-outs, fuses, etc, in the mains, for various purposes Institution object to this method of endeavouring to secure safety. Consider that such appliances should be confined to central stations, sub-stations and consumers' premises, and not placed in boxes underground. Submit that on several points the proposed regulations have been drafted too exclusively with a view to matters concerning the public safety, and that the "ensuring of a proper and sufficient supply of energy" has been to some extent lost sight of.

Edinburgh Corporation.—Submit, with respect to corporation undertakings, that the regulations should be made subject to any relaxation which on representation to the Board of Trade corporations might desire to have made, if they should at any time find it necessary or convenient in the public interest to have such a modification, without having to resort to the making of new and additional rules. Refer to relation of Corporation with respect to interests of the public, and hope that Board of Trade will differentiate the case of corporations from that of companies, by providing that the regulations may contain a power to the Board of Trade of modification on any incidental points at any time arising which might be granted in the discretion of the Board on the application of a corporation who are undertakers.

Eastbourne Co.—That the regulations as drafted would operate hardly against companies, and hope that they will be so modified that, while securing the safety of the public, they may not occasion companies which have been established for a long period, and have worked with great care and without accident, a heavy outlay to comply with them.

The proceedings concluded with a vote of thanks to the Chairman, moved by Alderman Gibson, of Manchester, and seconded by Alderman Myles, of Bolton.

LEGAL INTELLIGENCE.

THE NEW BRITISH ELECTRIC INSTALLATION CONTRACTORS.

The public examination of the directors and officers of the New British Electric Installation Contractors, Limited, under the Companies Winding-up Act, took place last week at the Worcester County Court before the judge, Sir Richard Harington. Mr. Warren Tree appeared for Mr. Millington and other directors and officers, and Mr. Halford for Mr. J H. Martin, a director. The examination was conducted by Mr. Luke J. Sharp (official receiver).

Mr. W. J. Hill, secretary of the company, said he was a clerk in the employment of Messrs. Griffiths and Millington. The signatories to the memorandum of association were Messrs. S. T. Castle, A. H. Parker, J. S Cook, R. J. Surman, A. Usher, W. H. Walter, and J. Duce. These signatures were only obtained to register the company, and none except Mr. Duce and Mr. Surman took any interest in the company. The company was largely promoted by Messrs. Griffiths and Millington. It was necessary that someone should be appointed secretary, and he supposed his name was as useful for that purpose as anyone else's. He had no salary, and had not kept any books, or been engaged at the offices of the company in any way. He kept the register of members and the share ledger, but nothing beyond that. During the first part of the company's existence the arrangement was that Mr. Duce, the secretary of the old company, was to keep the books. The new company was registered on October 29, 1892, the nominal capital being £25,000. A prospectus was drafted, and some 50 000 or 60,000 copies were circulated. Mr. Millington (chairman) and Mr. Duce (general manager and secretary of the old company) were the promoters of the company. Of the names of the directors appearing on the prospectus of the new company, Mr. Alfred Dickinson, Mr. Poulton, and Mr. Wheatley never took a share, and their names did not appear in the books of the company afterwards as being connected with it. The prospectus was made as attractive as possible to the public.

The **Official Receiver**: You were to put electric launches on the Severn?

Witness: That was one of the ideas.

The **Official Receiver**: Was one ever ordered?

Witness: No.

Mr. Hill, continuing, said the prospectus was extensively advertised in the Worcester papers. Notices about it appeared, and the witness admitted that a paragraph in one paper (produced) extolling the prospects of the company, was in his handwriting. There were some small sums subscribed by the public, but they were returned. The business was, however, carried on. Mr. Hill admitted that he had written to the official receiver stating that the value of the assets at that time, apart from the book debts, was £1.000, but a great deal of money and time had been expended by the old company in forming what was thought to be the nucleus of a flourishing concern. In the first place, £5,000 was to be paid for the assets of the old company, but after the failure to form the new company, the price was reduced to £3,000. The business was carried on as usual, and the directors in October, 1892, were Messrs. J. Millington, R. J. Surman, and J. H. Martin. These gentlemen were registered at that time as shareholders, but as a matter of fact the company did not proceed to allotment until February, 1893 Mr. Millington was registered as holding 47 shares of £5 each, the money for which was paid by Mrs. Duce, for whom Mr. Millington acted as trustee. Mr. Surman resigned in February of the present year. The £3,000 for the old business was to be paid by 6 per cent. debentures, to be redeemed by the operations of the company, so that the new company was to pay the debts of the old one. There was no power to issue debentures without a general meeting. This was done at a meeting in February or March, when Messrs. Millington, Duce, Martin, and himself were present. At that time the shares were registered, but the certificates were not issued until January, 1894. In reply to Mr. Sharp, Mr. Hill admitted that the debenture-holders had seized goods supplied by new creditors, and there was no probability of the debentures being paid unless the company was successful, or goods seized which were on the premises. Continuing, he said the debentures were allocated as follows: Messrs. Griffiths and Millington £1,400, Mrs. H. Duce £400 and £650, Messrs. Millington and Perry (trustees for Mrs. Duce) £425, Mr. R. J. Surman £125. The old company was in existence 12 months only, and during that time there was a loss, as shown by the balance sheet issued on January 31, 1893, of £2,000. During that 12 months £500 was allotted for services, and by the issue of the debentures the debt of £500 became a secured debt to the debenture-holders. The debenture-holders did not take shares in the new company. There had been no audit of the company's accounts. After the failure to float the company, an arrangement was made for Mr. Duce and Mr. Martin to supply £250 each, and to carry on the company as a private one. No money was paid to the directors for salary. There had been nothing paid to the debenture-holders. No promotion money was paid. The promoters and managers had been very heavy losers, to the extent of over £3,000. Of this, Mr. Millington had lost £1,300 or £1,400—this was actual cash lost—and Mr. Martin was a loser to the extent of about £800.

Mr. R. J. Surman, surgeon-dentist, Foregate-street, was also examined, and said for his £100 advance to the old company he received a debenture for £125 on the assets of the new. The debenture-holders had taken possession of all the assets of the company.

Digitized by Google

Mr. J. H. Martin, 37, Arboretum-road, now out of business, formerly manager of the Worcester Tramway Company, **Mr. James Duce**, electrical engineer, Denganwy. Llandudno, and **Mr. John Millington**, auctioneer and accountant, and chairman of the old and new British Electrical Company, were then examined, and Mr. Millington produced a balance-sheet, the only one he had been able to obtain from Mr. Martin, in March last, which showed that, excluding the shareholders and debenture-holders, the company was solvent. The assets and book debts amounted to £1,047. 16s. and the assets in stock to £640 15s. 4d Exclusive of the share and debenture holders, the liabilities amounted to £840. 11s. 7d., leaving a balance of £847. The old company, however, could not have been carried on without fresh capital being introduced.

The examination was adjourned until December 18.—*Worcester Herald.*

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA.

Mr. Justice Kekewich was asked on Tuesday, in a debenture-holder's action, to extend the time during which the receiver and manager of the Crompton Electric Supply Company of Australia might act. His Lordship said that, having regard to the very large number of companies now under supervision, it was important that there should be reality about the receiverships and manager-ships sanctioned by the Court. He declined to treat these matters *pro forma*, and would insist on being satisfied in each case that it was reasonable to continue the appointment. Counsel stated that the plaintiffs in the present case were the holders of £10,000 worth of debentures out of a total issue of £20,000. Negotiations were proceeding for the sale of the company's business, which it was hoped would be satisfactorily completed, and in the interests of all parties it was desirable to continue the receiver and manager for a short time further. On this statement his Lordship continued the appointment until April 30.

COMPANIES' MEETINGS AND REPORTS.

ELMORE'S PATENT COPPER DEPOSITING COMPANY, LIMITED.

A special meeting of this Company was held last week at the Company's works, Hunslet, when the following resolutions, passed by the shareholders at the annual meeting on the 1st inst.. were unanimously confirmed: "(1) That the board of directors may borrow money for the purposes of the Company's business to the extent of £100,000, subject to the provisions of Article No. 46 of the Company's articles of association, except so far as such article may be modified by this special resolution." "(2) That the ordinary share capital of the Company, which now consists of £182,390, divided into 91,195 ordinary shares of £2 each, all such shares being fully paid up, be reduced to £91,195, divided into 91,195 ordinary shares of £1 each, all fully paid up; and that such reduction be effected by cancelling paid-up ordinary share capital, which has been lost or is unrepresented by available assets to the extent of £1 per share on each £2 ordinary share."

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bucharest.—The Administration of the Roumanian State Railways invite tenders by November 30 for the supply of 12,000 porcelain insulators.

Betanzos.—Tenders are invited by December 28 for the concession of the electric lighting for 25 years of the town of Betanzos, Spain. Conditions of La Direccion General de las Administraciones Locales, Madrid.

London, S.W.—The Secretary of State for India is prepared to to receive tenders for caissons, air-compressing and electric light plant. Particulars are to be obtained from the Director-General of Stores, at the India Office, S.W., and tenders must be delivered by December 10.

Manchester.—The Corporation invite tenders by 10 a.m on December 2 for the supply and erection complete of two dynamos at the Foreign Animals Wharf, Mode Wheel. Particulars may be obtained at the city surveyor's office, Town Hall, Manchester, on deposit of one guinea.

Belfast.—Messrs. P. and F. M'Glade invite tenders for supplying and fixing an electric plant for lighting their new premises, The International, corner of York-street and Donegall-street. Copies of specifications can be had, and plans inspected, on application to Messrs. George Coombe and Co., consulting engineers, Castle-lane-place, Belfast.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.—The Administration des Télégraphes require tenders by December 18 for the supply of various large lots of pine telegraph poles. Special cahier des charges No. 26 at the Brussels Bourse.

Leicester.—The Corporation invite tenders for the supply and delivery of the necessary cast-iron pipes and connections, from 2in. to 24in, in diameter, required during 12 months ending December 31, 1896, for the Gas and Electric Lighting Committee. Specification and form of tender to be obtained from Mr. Alfred Colson, M.I.C.E., engineer and manager, Millstone-lane, Leicester. Tenders, addressed to Alderman Lennard, chairman, and endorsed "Tender for Cast-Iron Pipes, etc.," are to be delivered by 11 a.m. on December 7.

London, N.—The Great Northern Railway Company invite tenders for the supply of new and the purchase of old stores for 12 months from January 1. A list of the contracts and separate forms of tender for each contract may be obtained upon application to Mr. Martin, the stores superintendent, Doncaster, by whom every information will be furnished, and the patterns of telegraph and electric lighting material will be exhibited at the telegraph stores, Retford. Tenders, addressed to the Stores Committee, marked on the outside with a description of the stores tendered for, must be sent to the company's offices, King's Cross, in the envelopes specially provided, so as to be received by 10 a m. on December 7. Mr. William Latta, secretary, King's Cross Station, London, N.

Swansea.—The Corporation invite tenders for the following works: Contract No. 1: For the supply and erection of destructor and electricity supply station buildings complete, including engine and destructor houses, offices, approach roads, and yards. Contract No. 2: For the erection of a chimney shaft, 150ft. in height, with all necessary foundations and accessories. Contract No. 3: For the supply and erection of a dust destructor, including eight destructor furnaces, and four water-tube boilers, with all flues, dampers, and accessories necessary to the satisfactory setting to work of the same. Specifications, bills of quantities, and forms of tender of the engineers, Messrs. Kincaid. Waller, and Manville, 29, Great George-street, Westminster, S.W., for £3. 3s. each specification. The plans can also be seen at the offices of the engineers or at the Guildhall, Swansea. Sealed tenders are to be sent to Mr. Jno. Thomas, town clerk Guildhall, Swansea, endorsed "Swansea Dust Destructors and Electricity Supply—Tender for Contract No. 1, 2, or 3," as the case may be, at or before 4 p.m. on December 6.

RESULTS OF TENDERS.

London.—The following were the tenders for electrical work at the Metropolitan Asylums Board's Brook Hospital:

	A.	B.	C.
Siemens Bros. and Co., Woolwich	£2,004	£527	£475
W. H. Allen, Son, and Co., Bedford	2,060	—	—
J. H. Holmes and Co., Newcastle-on-Tyne	2,100	350	475
Crompton and Co., Chelmsford	2,139	366	551
Electric Construction Company, Wolverhampton	2,142	370	509
Johnson and Phillips, Charlton	2,170	630	360
T. Parker, Limited, Wolverhampton	2,312	412	521
Brush Electrical Engineering Company, Limited	2,428	480	378
Mather and Platt, Salford	2,605	415	465

A. Engines, dynamos, etc. B. Switchboards, etc. C. Batteries, etc.

Subject to the assent of the Local Government Board, the tenders of Messrs. Siemens Bros. and Co. for the engines, dynamos, etc., at £2 004, and for the batteries, etc., at £475, and the tender of Messrs. J. H. Holmes and Co. for the switchboards, etc., at £350, were accepted. The tenders for the wiring work and fittings, etc., at the Brook Hospital and Ambulance Station were as follow:

	Brook Hospital.	Brook Ambulance Station.
Electrical and General Engineering Company, 86, Leadenhall-street	£3,169 10 0	£289 0 0
Brush Electrical Engineering Company, Limited, 49, Queen Victoria-street	4,547 0 0	192 0 0
J. Sax and Co., Limited, 7, Ridgmount-street, W.C.	4,666 8 4	213 9 11
Fowler, Lancaster, and Co., Birmingham	4,685 12 6	228 0 0
Edmundson's, Limited, Westminster	4,643 19 0	350 15 0
Strode and Co., Regent's Park	4,878 0 0	334 0 0
Pritchetts and Gold, Soho-square	5,279 10 0	289 0 0
C. Nathan, Victoria-street, S.W.	5,063 0 0	630 0 0
H. F. Joel and Co., Finsbury-square	5,954 0 0	336 0 0
Hollingum and Saword, Holborn Viaduct	6,179 0 0	400 2 6
Slaters, Limited, Kensington	6,217 0 0	534 0 0

The tenders of Messrs. Julius Sax and Co., Limited, were accepted.

Glasgow—The Corporation have accepted the offer of Mr. Richard Miller to supply an electric light installation for the Family Home in St. Andrew's-street at a cost of £312.

Mitcham.—The tender of Messrs. Gray and Son, Leadenhall-street, for the erection of a lightning conductor on the water-tower at Mitcham Workhouse, for the Holborn Board of Guardians, has been accepted.

Killarney.—The tender of Mr. Chas. Leigh Clarke, of the Northern Counties Electric Construction Company, of 7, South-parade, Manchester, for the erection of an electrical installation as per specification at the Killarney Lunatic Asylum at the cost of £1,555, has been accepted.

Barnsley.—The Stafford Main Collieries Company, Limited, near Barnsley, having decided to have their collieries fitted with the electric light, the order has been placed with Messrs. A. Hirst and Son, of Crescent Works, Dewsbury. The plant will consist of a 600-light slow-speed dynamo and about 300 lamps.

Worcester.—The Town Council have authorised the purchase from the Brush Company of one 18-kilowatt transformer at £58. 16s. and sundry stores at £2. 10s. 3d., and also the acceptance of the tender of Messrs. Korting Bros., of 53, Victoria-street, London, to

Digitized by Google

provide and fix a condensing plant at the Powick generating station, in accordance with specification, at £430.

Paris.—For supply to the Direction Générale des Postes et des Télégraphes, Paris—(1) 6,000 iron cross-pieces with galvanised accessories, Mme. Vve Silvert Levent et Cie, à Bavay (Nord), 17,620fr. (accepted); (2) 12,000 ditto, same firm, 32 328fr.; (3) 9,000 ditto, Société de Gorcy, 25,191fr. (accepted); (4) 8 000 head cross-pieces, same firm, 23,072fr.; (5) 12,000 U consoles 12,000 long U cross-pieces, and 10,000 double iron consoles, MM Boucha-court et Cie, Paris, 31,490fr. (accepted); (6) 50,000 long consoles, Mme. Vve Silvert-Levent et Cie., 38,500fr. (accepted); (7) 50,000 ditto, Société de Gorcy, 38,800fr. (accepted).

BUSINESS NOTES.

Hawkshead (N. Lancs.).—The Parish Council have discussed the electric light question.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,049.

Lynn.—The Town Council have decided to obtain a provisional order for the electric lighting of the town.

Dover.—The electric lamps on the arches in Snargate-street were officially lighted for the first time on Saturday last.

Stroud (Gloucester).—A telephone exchange in connection with the National Telephone Company's system has been opened.

Douglas (Isle of Man).—The exhibition buildings, including the electric plant, at Bellevue, Douglas, have been completely destroyed by fire.

Leipzig.—The electric light, the *Gas World* says, has been succeeding beyond expectation in Leipzig. The orders amount to the equivalent of 31,500 16-c.p. lamps.

Berlin. -- The Grosse Berliner Pferdeeisenbahn Gesellschaft (horse tramway company) has submitted to the Magistracy various proposals for electric traction on its lines.

Societe Commercial Belge Gaz et Electricite —The ordinary general meeting of this Company will take place on December 11 at 22 rue des Palais, Schaerbeek, Brussels.

Nesten (Cheshire). — At a second meeting of ratepayers called by the District Council, it was resolved that the Council should go fully into the question of the cost of electric lighting and report on the subject.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended November 24 amounted to £1,067, as compared with £913 in the corresponding week of last year, being an increase of £154.

Wakefield.—The Corporation having applied for powers to borrow £25,000 on loan to defray the cost of the proposed electric lighting works, a Local Government Board enquiry is to be held on the subject to-day (Friday).

Catalogues etc.—Messrs. J. H. Heathman and Co. of 2 and 37, Endell-street, London, W.C., have forwarded us a copy of their illustrated price-list of extension ladders and steps, trolleys, fire-escapes, hose, garden engines, pumps, etc.

Queenstown.—The Queenstown Town Commissioners intend to apply to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 and 1888, to authorise the Commissioners to produce electricity for public and private purposes.

Russian Company for the Exploitation of Electric Energy.—With this translated title a company has been formed in St. Petersburg with a capital of 500,000 roubles. It proposes to erect a large central station near the Katharine Canal.

Shrewsbury.—In reference to the proposal for the electric lighting of the parish church, a vestry meeting has determined to reconsider the whole question in six months' time, with the view of introducing the new system for the winter of 1896.

Cheltenham.—The Town Council have decided to promote a Bill for the purchase of the gasworks, Alderman Vorman, the chairman of the Lighting Committee, citing many instances in which gas and electric lighting were running prosperously side by side.

Dublin.—A recent number of the Dublin *Evening Telegraph* contains a sketch map of the proposed important system of electric tramways in that city to cost about £300,000. The directors of the Dublin and Southern Electric Tramway Company are applying to Parliament for the necessary powers.

City and South London Railway.—The returns for the week ended November 24 were £946, compared with £957 for the corresponding period of 1894, being a decrease of £11. The total receipts for the half-year 1895 are £18,562, compared with £18,648 for the corresponding period of 1894, being a decrease of £86.

Cooper Bros. and Sons, Limited.—This Company has been registered with a capital of £40,000 in £10 shares. Object: to enter into a certain agreement for the acquisition of the business of Cooper Bros., now carried on at the Don Plate Works, and to carry on the business of electroplate and cutlery manufacturers in all its branches.

Brazilian Submarine Telegraph Company.—The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30 last, payable on December 20. The transfer books of this Company will be closed from December 13 to December 19, both days inclusive.

Davy Electrical Construction Company, Limited.—This Company has been registered with a capital of £10,000 in £1 shares. Object: to enter into an agreement with W. J. Davy, and to work and turn to account all or any of the properties by the said agreement agreed to be sold to the Company. The directors are W. T. Douglass, E. Berthier, and W. J. Davy.

Coops and Co., Limited.—This Company has been registered with a capital of £5,000 in £1 shares. Object: to enter into a certain agreement for the acquisition of the business of an india-rubber merchant and manufacturer, etc., as hitherto carried on by Charles Coops, at Duke-street, Liverpool, under the style of Coops and Co., and to develop and extend the same.

Portsmouth.—The Provincial Tramway Company are moving for parliamentary powers to use electricity as a motive force over the whole of its system at Portsmouth. The current is to be conveyed by overhead wires, and permission will be asked by the company to erect generating stations at each end of the town, and to use the electric current supplied by the Corporation.

Calne (N. Wilts.).—The District Council have discussed the question of adopting the electric light. A member said that if such a little place as Keynsham, with about 1,500 inhabitants, could afford to have the electric light, surely Calne might venture to do so. The existing gas lighting was described as "simply shocking." The matter was eventually referred to the Lighting Committee.

Bristol.—The clerk to the St. George Urban Council has announced that he had received copies of the Board of Trade regulations respecting the use of electrical power on the tramways. The regulations had been framed with the view of protecting the public against possible danger, and fixed the maximum speed of the cars at eight miles an hour, while at some junctions it must not exceed four.

Llanelly.—It is stated that the provisional order for the lighting of the town by electricity which was obtained by the Borough Council, has been purchased by Messrs. J. C. Howell, Limited. The Council authorised the Finance Committee to negotiate with Mr. J. C. Howell, managing director of the firm, and it is said that terms have now been arranged which will meet with the approval of the Council.

Lambeth.—A special meeting of the Vestry has been held. It was called by requisition to consider a motion moved by Mr. Bennetts, and which had been adjourned from a previous meeting, "That a special committee of 11 members be appointed to consider carefully all the information obtainable on the electric lighting question and report thereon to the Vestry." After a long debate the resolution was carried.

Apostoloff Automatic Telephone Parent Syndicate, Limited. This Company has been registered with a capital of £10,000 in £1 shares. Object: to acquire any patents, patent rights, etc., relating to improvements in telephones, and, in particular, an invention known as the Apostoloff automatic telephone, and to develop and work the same. The directors are M. Margowski, J. W. Cohen, and T. S. Hopcraft.

Gloucester.—With reference to electric lighting, regret has been expressed in the Town Council that it was proposed to light only a small area in the centre of the city, and the Mayor explained that the minimum distance had been purposely stated in the preliminary notice, as after the provisional order had been obtained they could, if they desired, extend it to the limits of the city. This was accepted as satisfactory, and the minutes were confirmed.

Bournemouth.—The Public Lighting Committee have received a notice from the electric supply company stating that a continuous supply of electric energy on all mains throughout the 24 hours would be given shortly. The Town Council adopted the report and also a number of recommendations for altering the position of public lamps and adding to the number of lamps in several districts where the lighting was considered insufficient at present.

Bermondsey (London).—The Vestry have decided to inform the Board of Trade that they intend to oppose the application of the Capital and Counties Electricity Supply Company for a provisional order for the lighting of the parish by electricity. It does not appear that the Vestry are desirous of undertaking the work itself, but that form of proceeding was the only way to get a copy of the order, so that the Vestry might see that the clauses did not injuriously affect the district.

Leith.—A deputation of the Leith Town Council have visited Glasgow for the purpose of inspecting the Johnston motor car. The deputation were appointed to visit Glasgow and see the car at work, in view of the application by the Edinburgh Street Tramways Company to use this new motor on their system. The motive power is "high-pressed superheated steam produced by means of special oil fuel, which is fed automatically to the generator." The deputation are said to have been "highly pleased with what they saw."

North Walsham (Norfolk) —The clerk to the District Council has read some correspondence with the Norwich Telephone Company as to the additional poles they wished to erect in the town to connect Mr. Reeve's house and his granary at the Great Eastern Station to the existing wires, and reported that, according to their contract, the wires, which should be 30ft overhead according to the measurements taken by the surveyor at different places in the town, were fixed at different heights, varying from 15ft. to the height named It was resolved that the Council should not entertain their application until the company had fixed the existing wires according to their contract.

Digitized by Google

Vienna.—The Gemeinde has received eight offers for the construction of electric railways in Vienna: (1) Eduard Lachmann, Hamburg; (2) Adolf Springer, Vienna; (3) Kontinentale Gesellschaft für elektrische Unternehmungen, Nürnberg; (4) Allgemeine Elektricitäts-Gesellschaft, Berlin; (5) Wiener Bankverein; (6) Neue Wiener Tramway-Gesellschaft, with the Anglobank and Siemens and Halske, Vienna; (7) Bauunternehmung Ritschel und Comp, Vienna, with the Union Elektricitäts-Gesellschaft, Berlin; (8) Stadler Stephan, Neupest.

Glasgow.—The new portion of the post office, which has been under construction for several years, has now been finally opened. The new plant for supplying electric energy and lighting the building has been erected in the basement of the new block There are three 80-i.h.p. engines of the Willans central valve type, suitable for a steam pressure of 120lb. to the square inch. The dynamos are mounted on the engine frame, and are of Crompton's make. The output of each machine is 465 amperes at a pressure of 108 volts, and at a speed of 450 revolutions per minute

Telegraphic Extension in Ross-shire.—Mr J G Weir, M P. for Ross shire, has been in communication with the Scottish Office regarding telegraphic extension to the poorer districts of Ross-shire with local guarantees, and has received a reply from Lord Balfour of Burleigh stating that the application will be considered along with others in the event of a grant for telegraphs being included in next year's estimates for public works in the Highlands, but adding that the Secretary for Scotland cannot guarantee that it will be found the most urgent case.

British Electric Traction (Pioneer) Company, Limited.—This Company has been formally registered with a capital of £100,000 in £10 shares. Object: to adopt and carry into effect an agreement expressed to be made between the Electric and General Investment Company, Limited, of the one part and this Company of the other part, and to carry on business as carriers of passengers and goods, electricians, engineers contractors etc The directors are Sir C. R. Wilson, Earl of Suffolk and Berkshire, J S Raworth, and E. Garcke Registered office: 1 and 2, Great Winchester-street, E.C.

Londonderry.—The resident electrical engineer (Mr. J. Christie) has reported to the Lighting Committee on the cost of proposed alterations and new lamps. The cost of having a new electric lamp erected in Marlborough-street would approximately be £72. 15s. The change in the position of an electric lamp at Mr. John Doherty's factory, Abercorn-road, would cost £5. 12s 6d. The cost of improving the lighting at the Synod Hall and other places in the city, about which reports were received, was also estimated. Alderman Miller complained of the light being turned off at midnight.

Electric Railways in Japan.—Application has been made to the Japanese Government for a charter for an electric railway connecting Yokohama with Fujisawa, touching *en route* at Kamakura, Shichiriga-hama, and Enoshima, the whole distance being 17 miles 42 chains. The gauge of 4ft 8in. is to be adopted, the speed will be 30 miles per hour, and trains are to leave both termini every 15 minutes. There are several projects for laying electric tramways in Tokio, the Japanese capital. Negotiations for amalgamation are proceeding between two of the principal companies, and hopes of success are entertained.

British Motor Syndicate, Limited.—This Company has been registered with a capital of £150,000 in £1 shares. Object: to adopt and carry into effect a certain agreement, the parties to which are not mentioned; to use, exercise, develop, grant licenses in respect of, or otherwise turn to account, any patents, licenses, concessions, and the like; to manufacture and deal in motors of every description, cycles, carts, wagons, ships, boats, launches, flying-machines, and carriages of all kinds; as electrical and mechanical engineers, machinists, fitters, metal-founders, millwrights, smiths, wire-drawers, tube-makers, metallurgists, saddlers, rubber merchants, etc.

Hornsey (Middlesex).—The County of London and Brush Provincial Electric Lighting Company, Limited, have written to the Hornsey District Council proposing to light the public thoroughfares of the parish. Mr. Bell thought the Vestry, when they had their wharf and dust destructor finished, might provide their own light, that was supposing they had not given up their rights in the matter. The Chairman replied that the parish had not given up any rights in the matter. It was probable when the apparatus was fully established in the parish they might have an installation at the Vestry Hall, but he could not say anything definite on the point just then.

Rockhampton Electric Lighting Company, Queensland.—The following is an extract from a letter received from this Company by their agents, Messrs. Wm. Coward and Co, of 27, Leadenhall-street, London, E.C.: "Through the medium of the electrical journals I have been watching the rapid growth of the electric light industry and its effect upon the gas enterprise. The keenest possible attention appears to be given by both sections of English lighting companies to everything calculated to further their interests. If there are any special features in connection with the commercial policy adopted by these companies which you consider might work favourably out here and likely to commend themselves to my directors, I shall be glad if you would refer to them for their consideration."

Camberwell (London).—The General Purposes Committee of the Camberwell Vestry have recommended that the consent of the Vestry be given to the application of the County of London and Brush Provincial Electric Lighting Company, Limited, for a provisional order for the electric lighting over the whole of the parish, with he exception of that portion of the parish over which the Crystal Palace Lighting Company have powers. An amendment was, however, carried, which stated "that the assignment of a monopoly of electric lighting in this great and growing parish to a private company for so great a period as 42 years demands such grave consideration that the Vestry hereby appoints a special committee to consider and report upon the question of the electric lighting of the parish in all its bearings."

Newport (Mon.).—It has been determined to extend the area of electric lighting in Newport by laying mains in Cambrian-road, Fields Park-road, Fields Park-crescent, Bryngwyn road, Godfrey-road extension, and Fields-road extension. This extension will cost nearly £1,000. It has also been determined to supply electric current to private consumers during the day, and to switch out the arc lights in the principal streets at midnight. A complete report as to the cost of the electrical installation has been ordered to be prepared, with the idea of applying to the Local Government Board for sanction to the borrowing of the necessary money over and above the £28,000 already sanctioned to cover the cost of additional works, etc. The street and private installations, as far as they have gone, have proved a complete success.

Wells (Somerset).—The Sanitary Committee have reported, as the result of their negotiations with the gas company, that the latter had offered the works to the Council for £19,680, which the committee considered out of the question. The committee were prepared to recommend the Council to give a sum of £12,700, which they considered the value of the undertaking. This sum the company had declined to accept, and as they offered no alternative nor accepted the offer to light the city, negotiations as far as the committee were concerned were at an end. The Council consequently have formally resolved to apply to the Board of Trade for a provisional order to light the city with electricity, and £50 has been voted to deposit with the Board of Trade, a proposition to offer the gas company £15,000 for their concern being rejected.

Holyhead.—A correspondent writes: "I discover the following is the extraordinary situation of the Holyhead Pier Station, where all the mails and most of the important passenger traffic between England and Ireland pass four times daily. Distant more than a mile from the fine harbour station, there are neither telephonic, nor telegraphic, nor acoustic nor any means of communicating between the two points. Last year, I was told the engine that had to push the train up from the pier being in the rear, nearest the sea, a leading carriage derailed at the points. The officials in Holyhead could not be informed of this (nor can they now be informed of any the most frightful disaster on the pier) until a porter could walk up the line in the dark. It may be against a hurricane and driving rain or snow. Such a fact at this date might seem altogether incredible."

Tramways Construction Company, Limited.—This Company has been registered with a capital of £100,000 in £10 shares. Object: to enter into certain contracts for the construction, repair, and maintenance of, and to construct, equip, repair, and maintain, under contract or as owners, tramways and other roads or ways (to be used for traction by electricity, steam, or other agency), bridges, subways, sidings, waterworks, etc, including the laying of pipes for distribution; buildings of any kind; telegraphs and systems of telephonic communication or electric lighting; and to work and carry on, under contract or as owners, or otherwise, any electric or other tramways, etc. The signatories are: H. R Beeton, 6A, Austinfriars; J. B. Concannon 28, Austinfriars; W. Hadenstein, H. W. Jefferson, H. Oppenheim, J. Morris, H. Marnham. Registered office: St. Michael's House, St. Michael's-alley, Cornhill, London.

Ipswich.—On the minute recording the interview with Mr. Paris on behalf of the County of London and Brush Provincial Electric Lighting Company coming up for confirmation, the Town Clerk informed the Paving and Lighting Committee that he had received a letter apologising for delay and saying that the manager had been ill. The Mayor said the matter had not been referred by the Council to this committee and they really had no jurisdiction in it. The Town Clerk said he had received from the company a map showing the compulsory area they proposed, and he found it did not include anything like all the streets the Council on a former occasion decided should be included in the area in which it should be compulsory on the company to supply electric light. It did not include Mr. Pratt's premises. He returned it and pointed this out, and the company replied that once more there had been an error.

Wilmslow (Cheshire).—The District Council have received a letter from Mr. S V. Clirehugh, electrical engineer, Manchester, with regard to the question of electric lighting in the district. Mr Clirehugh's letter stated that an agreement had been entered into between the Alderley Edge District Council and himself to transfer the powers which had been conferred upon that Council to a company, of which he was engineer, and that the company were anxious to obtain powers, subject to the control of the Wilmslow Council, to supply electricity in the Wilmslow town and district. They were anxious that no delay should occur, and he suggested that a committee should confer with him on the subject. They would, if possible, apply at once to the Board of Trade for a license, so that the electric light might be available for next winter. After discussion a committee was appointed to meet Mr. Clirehugh.

City of London Electric Lighting Company, Limited.—The directors announce the issue, at a premium of 28 per cent., of £100,000 5 per cent. debenture stock, being the balance of an authorised total of £400,000, redeemable at 125 per cent., on six months' notice, after 1910, and secured by a first charge on the

Digitized by Google

whole undertaking, subject to certain restrictions. The Company was formed in 1891, and has a fully-paid share capital of £800,000. The total expenditure on freehold and leasehold land, machinery, buildings, plant, etc., amounted at June 30 last to £1,078,684; and, on the same date, stores, cash at bankers, investments, and other assets represented £130,938. The gross income, as shown by the published statement of accounts, was for 1893 £39,663, and for 1894 £68,864; whilst for the nine months ending September last the revenue came to £60,390. The list of subscriptions opened yesterday, and closes to-day for both town and country.

Newcastle.—There is considerable opposition to the Town Council's plan of leasing the tramways which would commit the town to the adoption of the cable system for the next 21 years. Another meeting has been held in furtherance of the campaign of protest against the Corporation's settlement of the tramways scheme. There is now some talk of carrying the opposition to Parliament. Mr. J. G. Cranston, of 24, Grey street, is acting as secretary to the opposition movement. An elaborate printed statement has been issued giving the facts and figures on which the opponents of the Corporation's scheme rely. In this statement it is argued that the reconstruction will cost the ratepayers £230,000, while the monopoly of working the trams is to be given away to a private company who will have a concession worth £50,000 put into their pockets and the chance of earning 40 per cent. on the capital required to work the lines. The writer of this statement pins his faith to the electric as being better than the cable system proposed.

Feltham (Middlesex).—A meeting has been held in the Public Hall to discuss the question of introducing the electric light into the village. Mr. Quihampton opened the meeting by reading a copy of a circular which had been distributed: "Proposed Electric Lighting for Feltham.—We, the undersigned, think it desirable that electric lighting should be introduced into the village, and as a commencement to take in from the railway bridge to the Water Splash. From the estimates already received, we are of opinion that the price would compare very favourably with the present system of lighting. Both for private and business purposes, the electric light is unequalled, giving neither trouble nor dirt. The estimated cost, including working expenses for about the first three months, would be upwards of £1,000, of which sum half has already been promised." In the end, the Chairman stated that Mr. Holland would be glad to give his services as secretary to a proposed company, and it was agreed that someone should call upon those interested in the subject to try and get them to take shares.

Brighton.—A correspondent writes: "Although the great extension of electric lighting in the main thoroughfares of Brighton, inland as well as on the entire sea-front, will not be in complete working order until early next year, some of the streets will have the benefit of the new system before the scheme is realised in its entirety. Queen's-road, for instance, has been so illuminated since a few days ago, and coming at a time when the visiting population is greatly augmented on account of the conference of the National Conservative Union, the innovation will serve a useful purpose in demonstrating to visitors on their way to and from the station that the enterprise of the Corporation is not limited to the front-line alone. No one can fail to be struck with the great improvement effected from the central railway station to North-street, and not the least pleasing aspect of the innovation is the great utility of the new pattern of lamp standard, with its ornamental projecting arm, to which the lamp is affixed, the design being that of Mr. May, the borough engineer and surveyor. As the installation progresses, other streets will gradually be electrically lighted."

St. Pancras (London).—The report by the chief clerk on the work of the Electricity and Public Lighting Department during the year ending May, 1895, has been issued. The general increase of business is graphically shown by the following table:

	Increase. From Jan., 1893, to Jan., 1894. Per cent.	Increase. From Jan., 1894, to Jan. 1895. Per cent.
Number of consumers	47	44
Sale of current at 6d. per unit	8	17½
Sale of current at 3d. per unit	94	212
Supply to private houses (exclusive of trade premises, etc)	34	49
Number of lamps connected (in 16 c.p.)	24	22
Highest load point	17	23
Total sale of current (excluding public lighting)	13	33
Money value of current consumed	10¼	26

London County Council.—The Fire Brigade Committee, on Tuesday, recommended to the Council that the seal of the Council be affixed to agreements (in duplicate) with the Post Office in respect of two fire-alarms in Rheidol-terrace, Islington, and Teviot-street, Poplar, and in respect of telephonic communication between the Watling-street station and the firemen's watch-boxes in Mansion House-place, Upper Thames-street, and the General Post Office, Clerkenwell station and the watch-box on Snow-hill, White-cross-street station and the watch-boxes in Love-lane and Bartholomew-close, Bishopsgate station and the watch-boxes in Eastcheap and Finsbury-circus, St. John's Wood station and the watch-box in Kilburn-park-road, Kennington station and the Battersea river station. The Parks and Open Spaces Committee reported that the Post Office authorities had applied for permission to erect a telegraph pole on Nunhead Green to carry a wire to a fire-alarm post. The committee thought it desirable, as far as possible, to avoid the erection of posts and wires on and over the public recreation grounds, and the Fire Brigade Committee, having been informed of their opinion, have decided to have the wire laid underground. The committee therefore recommended that permission be given to the Post Office for the wire across Nunhead Green to be laid underground.

Llandudno.—The Urban District Council have received applications from two quarters for permission to lay down electric tramways in the district. As the Council expect shortly to receive a third application, they deferred their decision until its arrival. They also instructed that it should be ascertained from various electrical engineers their terms for advising and reporting upon the electric lighting of Llandudno. The Electric Lighting Committee resolved that the engineer be instructed to write to the following electrical engineers, forwarding copies of the Llandudno electric lighting provisional order, and asking for their terms for advising and reporting generally upon the whole question of the electric lighting of Llandudno—viz., Mr. F. H. Medhurst, London; Mr. Preece, London; Mr. T. L. Miller, Liverpool: Messrs. Kincaid, Waller, and Manville, London. This having been done, the committee recommended that the terms of Messrs. Kincaid and Co. be accepted for a report, and on the matter coming up in the Urban Council the chairman moved, and Mr. E. Jones seconded, that the report be adopted. Mr. Bellis moved an amendment that the Council invite competitions for the supply of electric light, and then take the advice of an eminent engineer on the schemes submitted. Mr. Marks seconded the amendment, and it was carried. It was subsequently decided that all applications as to tramways should be referred to a committee.

Aberdeen.—The directors of the Aberdeen District Tramways Company have had under consideration the terms on which the company would be prepared to dispose of the tramway system to the Corporation, but no definite conclusion was arrived at. The School Board have remitted the question of introducing the electric light into the Board's offices to the Finance Committee with powers to act, the first cost being estimated at not more than £20. The Gas Committee of the Aberdeen Town Council recently reduced the price of electrical energy, offering to supply a daylight service for electric motors at a reduction of 25 per cent. on the cost for lighting. Already the public are taking advantage of this decision. The workshops at Gordon's College are fitted with two motors, where 6 h.p. is available for driving wood and metal working machinery. Councillor Fleming has also in daily use an electrically-driven crane for lifting and transporting large logs of wood from end to end of his establishment at Albert Sawmills. With a view to encouraging the public to avail themselves of electric motors as labour-saving appliances, the Gas Committee have arranged with Mr. Spark, electrical engineer, Belmont-street, to exhibit a turning-lathe at work in their gas-stove depot. The lathe, which has been made by Mr. Henry Milnes, of Bradford, is of high-class manufacture, all the working parts, including toothed wheels, being cut from solid cast steel, and embodies several ideas which Mr. Spark suggested to the maker.

Worcester.—The City Council have received from the Water and Sewerage Committee an important report, involving the expenditure of upwards of £30,000 for purposes of water supply, including the following work: brick building for electric motors, pump wells, pumps, etc, and bridge from waterworks to the island; estimated cost, £1,703. At the last Council meeting Mr. G. H. Williamson moved that Messrs. J. Ward and Sons should provide and fix a steam-pipe apparatus with McDougall's steam-traps, as mentioned in their estimate, for heating Powick generating station, for £70. 5s. The generating station was, he said, completed towards the end of last autumn, and then no provision was made for heating the large hall in which the engines and turbines were worked. During the long and severe frost the employés had had to use much more coal than was otherwise required, and had also suffered great inconvenience. It was very injurious to the machinery to have great changes of temperature. This motion led to a long discussion upon the cost of the electricity works, and an amendment was moved, "That it be an instruction from the Council to the Electricity Committee that they should supply the Council with a statement of all costs and expenditure incurred from the commencement of the electricity works to the present time, and also a statement showing all income from all sources up to the present time, and the amount of all works entered into by them and not yet carried out." The amendment was, however, rejected, and the original motion was carried.

The South Staffordshire Tramways.—This company is approaching another critical period. Their last license for the use of steam on their lines is fast running out, and the Board of Trade have intimated that they will not renew the license further than December 31 unless the sanction of the local authorities is first obtained. With reference to a new system of traction much has been said about electricity with the overhead wires, but it is stated that there is a consensus of opinion upon its good qualities and cleanliness, only the West Bromwich and Handsworth authorities being opposed to it. The following letter has been received by the Tipton Urban District Council: "Walsall, November 25, 1895. Dear Sir,—South Staffordshire Tramways—We think you should know that there are persons at the present time who are prepared to take over the tramways, discharge the liabilities of the present company, equip with cable that part between Carter's Green and Handsworth, and equip electrically on the overhead system the rest of the line. In view of this, we think any further extension of the steam license is undesirable. It is not to the interest of the debenture-holders (some of whom we represent) any more

Digitized by Google

than of the public that the present engines should be perpetuated, and we look upon the money now being spent in repairing them as thrown away. We recognise the inconvenience of the stoppage of the traffic, but the question is whether it is not better to face a temporary stoppage in order to force the adoption of a better system than to allow matters as they are.—Yours faithfully, DUIGNAN AND ELLIOTT.—G. M. Waring, Esq., clerk to the Tipton Urban District Council."

Cardiff.—For some months past Charles-street, Cardiff, has been illuminated by gas lamps with incandescent burners, the departure being introduced with a view of ascertaining if the lighting of side streets at Cardiff could be improved by the system without any increase of expenditure. A local reporter has asked the borough engineer if the new light was a success. Mr. Harpur replied without hesitation in the negative. He added, "The expenditure is precisely the same. The same quantity of gas is being used. I have gone carefully into the matter of the cost, and there has been no economy whatever, notwithstanding the fact that the burners are of the most improved type. I don't think the burners are at all suitable for street-lighting." The Chairman of the Lighting and Electrical Committee has stated that it will be necessary to put down additional plant at the electric light works. The Exhibition Committee would require 101 arc lamps and 539 incandescent lamps, but they also added to that number 25 per cent. for contingencies. This would necessitate about 350 additional horse-power, and as the Corporation would be compelled very shortly to extend their plant to meet the requirements of private consumers, he suggested that an application be made to the Local Government Board for power to make such extensions in time to supply the exhibition. The whole question was referred to a sub-committee to report upon, and the Chairman promised to call a meeting of the General Committee as soon as the report was ready for presentation. Subsequently, Mr. Munn stated that the committee could not take further orders for private lighting until the plant was increased; in fact, they could not comply with the orders they had received.

Royal Electric Company of Montreal.—Messrs. Coates, Son, and Co. have been authorised by the directors of the Royal Electric Company of Montreal to receive subscriptions at 105 for £34,000 4½ per cent. first mortgage debentures, the balance of a total of 750,000dol.—say £154,000—the first portion of which was offered a year ago. The debentures, which rank *pari passu* with those already issued are secured on the immovable property, machinery, and plant, subject only to certain other charges amounting to £5,525, and all maturing for payment by 1897. The debentures are redeemable to the extent of £1,700 per annum, by annual drawings at 105, commencing April 1 next, or by purchase on the London and Montreal Stock Exchanges at a lower price, the company, however, reserving the right to redeem at 110 at any time, on six months' notice, the whole of the debentures then outstanding. The Company was formed in 1884, and has a capital of 1,500,000dol., of which 1 000,000dol. is paid up, and there is also a reserve fund of 308,000dol. The prospectus states that regular quarterly dividends at the rate of 8 per cent. have been for some time past distributed on the paid-up capital; and that the net revenue from the contract with the Montreal Corporation is alone more than sufficient to provide for the interest on the debentures, while apart altogether from such contract, the net income from incandescent lighting, commercial arc lighting, the supplying of motor power, and the manufacturing department, is more than is required for both interest and redemption charges. The value of the assets at the end of the last financial year, according to the certified statement of accounts, amounted to 2,226,000dol. The subscription list closed last Monday.

Sheffield.—With reference to the scheme of electrical tramways mentioned last week, a reporter of the Sheffield *Telegraph* has interviewed Mr. W. Page, the representative of the London and Provincial Tramway Company Syndicate. Mr. Page was very busy looking after the lithographing of the plans—all the preliminary work is being done in Sheffield. He said: "our system will be substantially the overhead electrical system, and when the time comes for equipping the lines we shall include all the latest and best improvements in our scheme, though the system is already as nearly perfect as we expect to see it. To illustrate," he added, "the readiness with which overhead electrical traction is adopted, I may mention that at Milan there are poles and wires under the very shadow of the cathedral—one of the grandest piles in the world; and at Genoa the poles and wires run down a street—not a very wide street, either—lined with ancient palaces, built of marble." Mr. Thos. Crookes, of the Atlantic Works, Sheffield, writes: "I venture to ask if some of the various heads and falls on the Rivelin which belong to our Corporation could not be be utilised for producing the necessary motive power for working the tramways by electricity or by cable, or the two combined, instead of erecting large steam-engines for that purpose. The Corporation own on the Rivelin 17 mills, or, rather, heads and falls (as some of the mills have gone, and others are going to rack and ruin), the net annual income of which is only between £500 and £600. The total head and fall from the top mill down to and including Walkley Tilt, is about 260ft., which probably is equal 400 h.p. at the least, and would propel cars by electricity on tramways three or four times the length of the present system."

Tottenham (Middlesex).—The General Purposes Committee of the Tottenham District Council having preliminarily considered the subject of the electric lighting of the parish, have found—as far as they were able to ascertain—that unless accompanied by a large demand from private users the cost of public lighting by electricity would be largely increased over that of gas; further, that the question of the introduction of an installation of electric light for the district was essentially one for consideration by an electrical expert, and if the Council decided to proceed they thought that such an expert should be engaged to consider the question and report to the Council. With the view of having full information on the question of improving the public lighting of the district, the committee recommended that arrangements should be made for a trial of the incandescent gas light in certain parts. Mr. Malone moved that the Council should appoint an engineer. He understood that Mr. Medhurst, an electrical engineer appointed at Fulham, had reported that when parishes had enough dust and refuse the burning of it enabled them to light the streets for nothing, and to make a profit for the relief of the rates by supplying the light to private consumers. The report and recommendations of the committee were agreed to, and notice was given to move that the Council invite electrical engineers to submit schemes, designs, reports, and estimates; annual cost of working the system; advantages and disadvantages which would arise on profit and loss as compared with the present system of lighting, and whether it would be advantageous to establish the electric light in conjunction with a dust destructor; and that premiums of £50, £30, and £15 be offered for the first three schemes selected.

Folkestone.—A special meeting of the Folkestone Town Council has considered the electric lighting question. The notices on the agenda paper were as under: "(1) To consider the expediency of applying to the Board of Trade for a provisional order to be granted to the Corporation and Urban District Council of Folkestone to light the whole or any part of their district with the electric light, and as to site of generating station, plans, estimates, and details to be prepared and steps to be taken. In the event of the Corporation not passing such resolution to apply for a provisional order. (2) To consider an application on the part of Mr. Daniel Baker for the Corporation to assent to and support an application for a provisional order, in the above form, on the part of himself or his nominees. To consider from the Capital and Counties Electricity Supply Company, Limited, of their intention to apply on or before December 21 next to the Board of Trade for a provisional order to authorise the company to supply electricity for public and private purposes within the borough of Folkestone." The town clerk read a letter which he had received from Messrs. W. G. F. Webster and Co., in which reference was made to the offer of Mr. Webster to light the Leas at a certain specified cost, and stating that if the Corporation decided to go on with the matter, they would undertake to get the installation completed next year. Councillor Baker proposed a formal resolution prepared by the town clerk. He remarked that they were face to face with an alternative. They must either get a provisional order to light Folkestone themselves or they must allow someone else to do it. In his opinion they should do it themselves. They saw there were two other notices on the paper—one from himself and another from another company, and they heard there was another application from Mr. Webster. No doubt they would get any number of others who would be only too pleased to step into the gap. If they got a provisional order and thought fit to sell it they could make £500 or £1,000 out of it. It was imperative that they should have electric light at the west end of the town, and unless the Corporation were prepared to supply it he must do it himself. The motion was carried unanimously.

Swansea.—A report by a sub-committee of the Swansea Corporation on tramway purchase, after stating that it is incumbent on the Corporation to obtain entire control of the public roads, proceeds as follows: "Another very important factor which has occupied the attention of your sub-committee is the question of running tramcars by electricity. This is desirable, as the heavy gradients in many parts of the road are a great strain on the horses employed, and if this can be arranged, the success of the scheme for the electric lighting of the borough, which has recently been adopted by the Town Council, will be fully assured. The provision of a day load by keeping the machinery employed at a time when there is no demand for lighting would effect a very material reduction in the cost of electricity all round. The working of the cars by electric traction would at once form such a day load Your sub-committee are of the opinion that sufficient electricity for such a scheme can be provided at a cost which would reduce to almost one-half the amount of the cost of electric lighting anticipated by the report to your Electric Lighting Committee, and if these results are attained electric lighting might be provided within the borough at a cost below that now charged for gas by the Swansea Gaslight Company. There would also be a great saving of cost in the wear and tear of the roads. The following terms have been provisionally arranged with the tramway company: (1) The Corporation to purchase the tramlines, depots, and all other rights and property of the tramway company within the borough (exclusive of rolling-stock) for the sum of £32 000. This amount is made up as follows—namely, £10,400 to enable the company to discharge their existing mortgage debt the balance to be expended by the company in the purchase of motor cars for working the tramway system. (2) The Corporation to double the lines as far as possible, so as to admit of a sufficiently rapid service, and to put in the necessary posts, wires, and bonds, so as to make the line suitable for electric traction. (3) The tramways to be leased to the company for a term of 21 years. (4) The annual rent to be (*a*) the interest annually paid by the Corporation on the total money borrowed with ½ per cent. in addition; (*b*) a sinking fund on tramway expenditure, for reconstruction and additions at 3 per cent. and 21 years; (*c*) a sinking fund on the balance, being purchase-money for tramways, roadways, costs, etc., at 5 per cent. and 30 years. (5) The Corporation to supply electrical power, at a price to be

Digitized by Google

agreed upon. (6) The lines to be kept in repair by the Corporation at cost price, but no charge to be made for renewals, which are represented by sinking fund."

PROVISIONAL PATENTS, 1895.

NOVEMBER 18.

21893. **Improvements in electric light fittings.** Nelson Dadge, 8, Great Portland-street, London.

21920. **Improvements relating to the electro-deposition of zinc and other metals upon iron and steel tubes.** James Greenwood, 4, South-street, Finsbury, London.

21924. **Improvements in or relating to wattmeters.** Georg Hummel, 323, High Holborn, London. (Complete specification.)

NOVEMBER 19.

21941. **Improvements in casings employed for electrical wires.** John Dugdill, jun., 17, St. Ann's-square, Manchester.

21993. **Improvements in combined motive power and electric generating and storing apparatus for the propulsion of movable conveyances and analogous power purposes.** George Arthur Washburn, 18, Buckingham-street, Strand, London. (Complete specification.)

21998. **Process for heating rivets electrically.** Gordon Paton Clark, 10, Lansdowne-road, Holland Park, London.

22004. **Improvements in and relating to electrical conduits.** James Fulton Cummings and William Clyman Yawkey, 45, Southampton-buildings, Chancery-lane, London. (Complete specification)

22006. **Improvements in and relating to electric railway signals.** John McCleod Murphy and Albert Francis Pierce, 77, Chancery-lane, London. (Complete specification.)

22023. **An improved thermodynamic process and apparatus.** Philip Arthur Newton, 6 Bream's-buildings, Chancery-lane, London. (Agnes Bates Wellington, United States.) (Complete specification.)

22028. **Improvements in protective coverings for the joints of electric cables.** George Gatton Melhuish Hardingham, 191, Fleet street, London. (The firm of Felten and Guilleaume, Germany.)

NOVEMBER 20.

22060. **Improvements in automatic telephone exchange system.** William Frederick Lounsbury, 57, Barton-arcade, Manchester.

22066. **Improvements in two-way switches.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster. (Complete specification.)

22074. **An improved means or method of driving or propelling electric tramcars.** Joseph Morton, Commercial-street, Halifax.

22112. **Improvements in the gearing and arrangement in an electric crane.** Douglas Potter, 68, Victoria-street, Westminster.

22120 **Improvements in electric accumulators or storage batteries.** Thomas William Allan, Arthur Powell, and Charles John Tibbits, 65, Chancery-lane, London. (Complete specification.)

22131. **A new or improved combined brake and dynamometer for loading and indicating the horse-power of the work transmitted through revolving shafting.** William White and Jacques Rodolphe Forrer (commonly called Rodolphe Forrer), 323, High Holborn, London.

22133. **Improvements in telephone message counters.** Friedrich Wilhelm Heinrich Hempel, Max Gumpel, and Alfred Maerker, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22142. **An improved electric battery.** Paul Falle, 40, Chancery-lane, London.

NOVEMBER 21.

22150. **Improvements in electric indicators for bells, telephones, alarms, and the like.** Stanley Walton, 59, Inverine-road, Old Charlton, London.

22207. **Improvements in electrodes suitable for electrolytic apparatus.** Carl Kellner, 46, Lincoln's-inn-fields, London.

22233. **Improvements in accumulators and their electrode plates, partly applicable to primary batteries.** Moricz Engl and Floris Wüste, 28, Southampton-buildings, Chancery-lane, London.

22234. **Improved means for protecting electrical and magnetic apparatus against the disturbing effects of electric railways passing in proximity thereto.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

22246. **Improvements in and relating to insulators and insulating conduits or tubing for electrical purposes.** Frederick Gwilym Treharne, 45, Southampton-buildings, Chancery-lane, London.

22252. **Improvements in direct electric current transformers or motor-generators.** Alexander Bewicke Blackburn and Thomas Large Boyden, 47, Lincoln's-inn-fields, London.

NOVEMBER 22.

22337. **Improvements in incandescent electrical lamps.** The Edison and Swan United Electric Light Company, Limited, and Alfred William Hill, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22346. **Improvements in stopcock locks and in electrical appliances used in connection therewith.** Charles Heyman, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 23, 1895, being date of application in United States.)

NOVEMBER 23.

22369. **An improved electric arc lamp for magic lanterns.** Herbert Charles Newton, 3, Fleet-street, London.

22408. **Improvements in dry voltaic batteries.** William Durant and Thomas William Baron Durant, The Arcade, Barnsley.

SPECIFICATIONS PUBLISHED.

NOTES.

Obituary.—We regret to learn of the death of Mr. John Muirhead, some time principal of the late firm of electrical engineers, of Westminster, who have erected telegraphs and carried out other electrical works in many parts of the world.

Electrical Engineering at the Cape.—An Electric Lighting and Power Act has recently been passed at the Cape of Good Hope, authorising regulations for the safety of the public. We understand that Mr. A. P. Trotter has been appointed Government electrician and inspector under this Act.

Popular Electrical Lectures in Austria.—With the view of popularising the knowledge of electricity, the Vienna Elektrotechnischer Verein has arranged for the delivery of a series of 10 easily-comprehended lectures on electrical subjects. Subscriptions for the whole course range from 6fl. to 15fl.

Power Transmission in Holland.—The repairing shops of the Dutch State Railways in Utrecht derive their motive power and are electrically illuminated from the electric light station, situated about a mile away. A full description of the installation appeared in a recent number of the *Tydschrift* of the Dutch Royal Institution of Engineers.

The Proposed School of Engineering in Sydney. The *Times* states that Mr. P. N. Russell, founder of an engineering firm in Sydney, who recently proposed to give the sum of £50,000 for the endowment of a school of engineering in the University of Sydney, has received a telegram from Sir William Windeyer, chancellor of the university, gratefully accepting his munificent offer.

Genoese Electrical Trams Interdicted.—It is stated that the police of Genoa have prohibited further operation of the electric trams on account of recent numerous accidents, which it appears are mainly caused by the heavy gradients in the city. Coming down the inclines the brake power has either failed or has not been promptly or efficiently applied, and the cars have derailed and caused considerable mischief.

Magnetic Observations on Hardened Steels have led Mr. J. O. Arnold, in his paper on "The Influence of Carbon on Iron," read on Tuesday, December 3, at the Institution of Civil Engineers, to the conclusion that (1) the magnetic permeability varied inversely as the carbon present; (2) the permanent magnetism was directly proportional to the carbides of iron present; and (3) in iron containing between 0·1 per cent. and 0·9 per cent. of carbon the permanent magnetism was directly proportional to the sub-carbide of iron present.

The Revised Electric Lighting Regulations.—Lord Kelvin, Mr. W. H. Preece, and Major Cardew, the committee of experts appointed by the Board of Trade, have, it is understood, presented their report on the questions which were referred to them as a result of the recent conference on the proposed new electric lighting regulations, presided over by Sir Courtenay Boyle, the permanent secretary of the Department. The principal matter on which the committee were asked to advise was as to the definition which should be officially laid down to constitute "low pressure." The tenor of the report is not at present known.

A Warning.—The man who, pretending plumbing purposes, used to gain access to houses with nefarious intent, has apparently given way to a more enlightened individual. Work, as our readers know, was recently commenced on the electric lighting installation at the Cancer Hospital, Fulham. Some quick-witted thief has utilised this information to effect a plausible entry into the building and appropriate watches, jewellery, and money. The secretary of the hospital states that by the careful measurements which the man took, and the marks which he put on the walls to show where the switches were to be, he effectually gulled the officials.

The Volatilisation of Carbon.—M. Moissan finds that when carbon is volatilised in his electric furnace it evaporates without melting, and that when the vapour condenses it always deposits as graphite. He also finds that aluminium carbide may be made, mixed with metallic aluminium, by the direct reduction of alumina with carbon in the electric furnace, and that when this carbide is treated with water it evolves chiefly marsh gas or methane (CH_4), not acetylene. This promises to furnish a new starting point for the methyl compounds and derivatives, which have hitherto been derived from the products of distillation of wood; and it casts some light upon the cause or origin of natural gas.

The Dangers of Paraffin Lamps.—The Home Secretary has written as follows to a correspondent who called his attention to the fact that during the six months ending last September there were, in London, 211 lamp accidents, 23 of which proved fatal, and asked whether the sale of cheap lamps could not be prevented by legislation: "Home Office, Whitehall, December 2. Sir,—In reply to your letter of the 26th ult., on the subject of the frequency of serious accidents from lamp explosions, I am desired by the Secretary of State to say that he hopes to be able when Parliament reassembles to secure the reappointment of the Select Committee which has sat in previous years with a view to legislation on the matter in question.—I am, yours very truly, W. P. Byrne."

An Electrically-Lighted Hindu Temple.—The *Times of Ceylon* learns that it is in contemplation to introduce the electric light into the Sivan Hindu temple at Kochicadde, on the main road to Mutwal, Ceylon. The premises of the Hindu place of worship are at present lighted by gas, and the trustees propose to substitute the electric light for gas; but whether they will introduce it into the interior of the building is a matter which is now under their consideration. It is said that if the Sivan Hindu temple introduce the innovation the trustees of the equally wealthy temple of the Natukotta in Sea-street "are sure to follow the example set by their more enlightened brethren." There is no question, we think, that the coming "Light of Asia" is the electric light. The temple event is one that Siva, when Brahma and Vishnu were absent, would probably have termed Parbutta—auspicious.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on the 2nd inst., Sir James Crichton-Browne presiding, when the following were elected members: Messrs. C. H. Berners, J.P., J. M. Bruce, M.D., F. Chambers, A. M. Chance, J.P., A. E. Fletcher, F. Fox, J.P., H. Seymour, K. T. Stewart, M.D., G. H. Strutt, F. Tendron, F.G.S., W. H. Warner, M. Webb, J.P., and Mrs. S. H. Phillips. The Right Hon. Lord Rayleigh, professor of natural philosophy, R.I., is to deliver six lectures on light. The Friday evening meetings will begin on January 17, when a discourse will be given by the Right Hon. Lord Rayleigh on "More about Argon"; succeeding discourses will probably be given by Prof. Burdon Sanderson, Mr. W. S. Lilly, Dr. John Murray, Mr. J. J. Armistead, Dr. Edward Frankland, Mr. A. R. Binnie,

Digitized by Google

Mr. Sydney Lee, Prof. T. R. Fraser, Prof. Dewar, and other gentlemen.

Electricity in Manufacturing Processes.—The second lecture in the series arranged by the Technical Instruction Committee of the Haslingden Corporation, in connection with the Victoria University, was recently delivered by Mr. F. G. Baily, lecturer on electrotechnics at University College, Liverpool, who illustrated his remarks by electrical apparatus specially requisitioned for the occasion, the Corporation steam-roller being pressed into service for the purpose of driving a dynamo. The address was an interesting one, and was well received. We wonder if Mr. Baily has seen the report thereof which appeared in the *Accrington Observer* of November 30? If he has not, he should see it. It is, like Frankenstein's galvanised monster, fearfully and wonderfully made. In it we have tripped across such delightful little pleasantries as "amphieres," "carbide of syllicum," "clorine," and "phosphorous"; while "armyised plates" occurs three times. We expected better things from Accrington.

Compensating Device Against the Effect of Electric Railways.—At the last meeting of the Elektrotechnischer Verein in Berlin Dr. O. Frölich read a paper on, and gave demonstrations with, a "Compensating Device for Measuring Instruments." He proposed, for compensating purposes, that a number—say seven—of thin wires be connected with the point of the rails nearest to the instruments and led to box-shaped frames which would be placed over each instrument. All frames, with their various windings, the wires of which were to be insulated from each other, would be connected in series. In the various leads small regulating resistances would be inserted in order to vary the pressure of the current at will. Dr. Frölich said that the experiments in Dresden and Pankow-Berlin with his device had given very satisfactory results, but the arrangement was unfavourably criticised by Dr. Kohlrausch. At the same meeting Herr Geh. Postrath Münch gave a "Communication on Induction Phenomena in Telegraph and Telephone Wires." He disputed the theory of the former telegraphic engineer, Herr Müller, that the disturbances on telephone lines were attributable to the passing over of currents. The discussion hereon was postponed.

The French Submarine Boat "Goubet."—*L'Energie Electrique* of December 1 contains a long article, signed 'E. L.," on an improved form of the French submarine boat "Goubet." The article is illustrated with outside views of the old form and the improved form of the "Goubet," but no drawings are given of the details of the interior. The boat is cigar-shaped, or rather fusiform, with bilge keels or flanges. It is 26ft. long by about 12ft. across, and is made of gunmetal. There is no deck, access being obtained by a manhole closed by a gunmetal dome about a foot high. The cross-section is circular, and the construction is calculated to support the water pressure of a depth of 160 fathoms. The weight is 10 tons, and the boat is manned by a crew of one officer and two sailors. Air for respiration is stored under pressure in steel cylinders, and pumps are provided to get rid of the used-up air. Normally, the "Goubet" floats with the manhole above the surface, but when it is desired to sink, the water is admitted to chambers provided for that purpose and pumped out again as required. The boat is driven by a screw, the motive power being obtained from a battery of 56 cells, weighing altogether about a ton, and giving a 20-ampere current at 90 volts for 14 hours. A Paterson and Cooper motor is used, geared down to drive the screw at 250 revolutions. The steering is done by altering the direction of the screw, which is fixed on a special joint, and there are also paddles worked by hand in case of breakdown. A curious feature is a long telescope-jointed tube, to be thrust to the surface for purposes of observation, and last, but not least, a weight is carried which in case of accident or difficulty occurring can be detached, and the boat then rises immediately to the surface. The "Goubet" has been tried on the Seine, and is to be further experimented with at Cherbourg. The French Government have not adopted the boat, but the present one is stated to have been sold to a foreign Power.

Mechanical Road Carriages.—The first of three Cantor lectures by Mr. W. Worby Beaumont, M.I.C.E., on "Mechanical Road Carriages" has been delivered at the Society of Arts. After commenting on the importance of the problem of easy transport to a country, he briefly traced the history of the attempts to produce practical road carriages, remarking that those who were working at the subject now might learn much from the failures of their predecessors. The first carriage that was at all successful was made in 1769, and was followed at a few years' interval by the inventions of Murdock, Symington, and Trevethick. For about a quarter of a century after the latter not much of note was done towards the construction of a practical carriage. Several of the inventors who took up the problem seemed to have disbelieved in the adhesive power of wheels, and therefore patented machines with legs meant to resemble those of a horse. Lack of sufficient boiler power was a frequent cause of failure. In 1831 a service of steam-coaches was established by Gurney between Cheltenham and Gloucester, but they were soon forced off the road by the action of the turnpike authorities. Hancock was the really successful man of early nineteenth-century work. He made a number of carriages of different forms, which ran successfully on the roads till driven off by the opposition of public and private interests. It was evident that 60 years ago a very remarkable degree of success had been attained, for it had become possible to build steam-coaches that could run from London to Birmingham and from Birmingham to Cheltenham. But still it could not be concluded that the failure of such carriages to establish themselves permanently was due solely to the opposition they encountered, and it was other than mere mechanical conditions that made it impossible to conduct traffic with them on better terms than could be done with horses. Mechanical means must in a sense be considered as secondary to the comfort of the passengers carried, for the public would not care a jot for the perfection of the motor if they had not comfort in the vehicle. Success, Mr. Beaumont said, would be obtained by the co-operation of the carriage builder and the engineer—not by the work of the latter alone.

Electric Power in Coal Mines.—Is the present position of power distribution by electricity such that we may use it with confidence for the whole of the power required at a colliery? To this query Mr. L. B. Atkinson, in *Cassier's Magazine* for December, replies "yes." The largest engine at a colliery is the winding engine, and suppose this, he says, to require to be capable of developing power at full speed of 1,000 h.p., which is an outside figure. This could be well replaced by two motors of 500 h.p., one on each end of the shaft of the drum, without gearing. There are numerous cases of dynamos and motors of this power working with ease and satisfaction and giving no difficulty whatever, and operated by ordinary mechanics with no more trouble than an ordinary steam-engine. Motors of smaller sizes are in use all over the world with universal satisfaction. Are the claims made for efficiency of electric distribution of power realised? he

Digitized by Google

asks. On this point the author has examined, carefully, tests made by himself and by others on electric power plants, and has arrived at this conclusion: While the efficiency of distributing electric power and its utilisation in the motors does come up to that claim, the efficiency of the production of electricity is not as a rule as high as is claimed, or as high as may be realised, and the reason is that sufficient account is not taken of the fact that the average load is considerably less than the maximum requirement. In one known case, where the efficiency of electric generation—that is, the proportion between the electric power delivered to the cables and the indicated horse-power of the engine—is as high as 86 per cent. at full load, it falls to 74 per cent. at half load, and to about 58 per cent. at one-quarter load. The reason for this is to be found in the power the engine takes to drive itself. The engine is generally arranged to work with an economical cut-off at the full load or maximum power, and consequently is larger than necessary for all smaller loads. It should be arranged to work with an economical cut-off at the average power. The moral, Mr. Atkinson concludes, is to use engines with automatic expansion valves, permitting the engine to work with a cut-off as late as half or five-eighths of the total cylinder volume when developing the maximum power, and working with a more economical grade of expansion at the average load.

Electric Lifts.—M. E. Hospitalier, writing on this subject in *L'Industrie Electrique* of November 25, says that the price of water for hydraulic purposes having been raised in Paris from 32 to 60 centimes (5½d.) per cubic metre has caused attention to be given to the question whether a motive power for lifts could not be adopted which would prove cheaper than water at the low pressure at which it is supplied by the waterworks company. Electric energy is now available in all the more important streets of Paris, and many designs of electric lifts having been invented and worked out by the manufacturers, their use is beginning to spread rapidly, so that, M. Hospitalier thinks, soon no house of any importance will be built without an electric or hydro-electric lift. With reference to price, it is remarked that while a cubic metre of water and a kilowatt-hour cost in Paris under the present condition of things exactly the same price—namely, 60 centimes—the water is supplied only at a pressure equal to a head of 30 or 40 metres, equivalent to 40,000 kilogram-metres per cubic metre used, while the kilowatt-hour represents 360,000 kilogram-metres, or 10 to 12 times as much as the water. With so large a margin available it is not surprising that electricity has been used for operating cable lifts worked directly from electric windlasses—a system adopted only in America—and also for supplying by some appropriate mechanism the water pressure necessary to work lifts on the hydraulic system. Electrically-worked chain lifts are counted by the hundred in the large American towns, where some of the "sky-scraper" buildings of 12 to 18 floors may have as many as 10 each, all at work during business hours. These carry 12 to 15 persons at once at a speed as great as three metres (say 10ft.) a second, and working during the daytime furnish a convenient output for the energy of the central station. They are not, however, used in Paris because there the public, accustomed to hydraulic piston lifts, do not think them safe. Moreover, besides this purely imaginary reason, the question of cost comes in to prevent their adoption. Putting in a new electric lift or converting a hydraulic lift into a chain lift costs about 10,000fr. (£400), while the additions necessary to a hydraulic lift to obtain the water pressure from electrically-worked apparatus cost less than 4,000fr. (£160). In some systems the conversion can be made without altering any of the existing apparatus, and the lift can be worked at choice either electrically or by using the town water supply. This gives a security against interruption of work which ought not to be neglected, and hydro-electric lifts of this pattern are consequently to be preferred.

The Durability of Porcelain as an Insulator.—Mr. James Pass, writing in the *Electrical Engineer* (New York) of November 20, says that it can hardly be questioned that porcelain, when skilfully compounded and carefully made, is an excellent and durable insulator. The recorded experience with this material for aerial lines in England, where it is used in preference to all other materials, should have some weight. It seems also to be well established, so far as laboratory tests can establish such claims, that porcelain, when well made, is a better insulator than glass, especially for high voltages. But how are we to know that the insulator which looks well and lasts well to-day will still be a good insulator five years hence Laboratory tests do not enlighten us on this point, and appearance is no indication whatever. Of course, certain gross faults may easily be detected—such as an imperfect vitrifaction, etc. But to make a porcelain body which is perfectly vitrified and yet has considerable strength to resist fracture requires experience and technical skill; and to make such a porcelain and cover it with a perfect glaze that will not crack in time, has from the dawn of the pottery industry taxed to the utmost the skill and ingenuity of the practical potter. This cracking of the glaze is called among potters "crazing," and is generally known by that name; perhaps from the fact that its unwelcome and unexpected appearance has driven so many good men to the brink, if not into the slough, of mental despair. The glaze used on porcelain is peculiar, and there is little resemblance between the formulæ for this glaze and those for ordinary glass. A porcelain glaze must attach itself very firmly to the body when heated to near the melting point of that body, and it should have as nearly as possible the same coefficient of expansion as the body which it covers. The exact adjustment of glaze to body is difficult to attain, the glazes having usually a larger coefficient of expansion than the bodies. "Crazed" porcelain should never be used as an insulator, for when subject to moisture the fissures in the glaze fill with water by capillary action, forming excellent channels for leakage of current. It should be a source of regret that such large quantities of defective porcelain have been used in the construction of electrical devices. Mr. Pass knows of reputable manufacturers of electrical apparatus who have assembled and sent out in the market to do service in permanent installation tons of this defective porcelain; and he has again seen some of the same articles that had evidently done service in a damp place and every crack in the glaze was filled with verdigris. Good porcelain can be had, and at reasonable prices as compared with the cost of porcelain for other purposes, but poor porcelain that is "crazed," or is liable to craze, or is imperfectly vitrified, will be used because it is cheap and "passes inspection." It should be required that all porcelain bear the manufacturer's name, and a rigid inspection should prevent the use of "crazed" porcelain in new work, or its continued use in old work. This, Mr. Pass thinks, would in a short time give us a better insulating material, and one that could be depended upon.

The Light Railways Conference, which was held last Thursday at the Westminster Palace Hotel, enjoyed a good attendance, amongst those present being Sir A. Rollit (chairman), Sir David Salomons, Major Rasch, M.P., and representatives of various county councils, local authorities, and public bodies, including the Institution of Elec-

Digitized by Google

trical Engineers, Tramway Institute of Great Britain and Ireland, and the Surveyors' Institution. The Chairman, in opening the proceedings, said that latterly great interest had been taken in light railways, but it was to be regretted that the interest had chiefly manifested itself in the work abroad. The instances of light railways in this country were few and exceptional, probably owing to the faulty character of the Acts of Parliament under which they had to be constructed. Some of those Acts had remained dead letters, and the costly procedure and practice attending them had been such as to prevent the progress of the enterprise in Great Britain. The present conference had been called together in the hope that they might be able to advance legislation, and with that object the meeting would be asked to discuss the general principles of the question of light railways and the leading principles and provisions of Mr. Bryce's Bill. The only country where so far the State had not co-operated in the making of light railways was Holland; but the lesson to be drawn generally from the experience of other countries was that they should ask the State to do something. Belgium, France, Hungary, and Italy had their light railway systems supported by various authorities under various conditions, and we in this country would have to be guided by local circumstances. Major Rasch, M.P., moved: "That this conference heartily approves the establishing of light railways under an improved system of procedure and regulations, and with State and local aid to private enterprise; and urges her Majesty's Government to introduce proposals for legislation on the subject at the earliest possible opportunity during the ensuing session of Parliament." Mr. Carruthers Wain, president of the Tramways Institute, seconded the motion. He urged that it was a waste of time to discuss Mr. Bryce's Bill, for it was merely the outcome of the laborious series of platitudes compiled by the majority of the Light Railways Committee. It was impossible to base any legislation on their suggestions. Mr. Elliot Cooper related his experience in the construction of 50 miles of light railway from Cremona to Piacenza, in Italy, showing that the road was taken advantage of in some portions of its length. The great defect of the Bill of last session was, he said, that it did not lay down anything approaching to hard-and-fast lines in order to guide the Board of Trade as to what it was they had to sanction. The regulations of the Board of Trade should be entirely altered. An amendment proposed was lost, and the original resolution was carried unanimously. Mr. Vaughan Davies, M.P., then moved: "That those present form themselves into an association, with power to add to their number, to promote the object of the previous resolution, and that Mr. J. Wallis Davies be appointed secretary," and this motion was eventually adopted.

Anglo-Foreign Technical Dictionaries — good ones, that is to say—are not very plentiful even in these days of advanced science; but especially, and perhaps necessarily, are those scarce which relate to the domain of electricity. The ever-useful "Karmarsch," it is true, has not dallied in the progress of its editions in the insertion of electrical terms, but then it is always a general dictionary, covering a wide field, and therefore expensive. We have before us the very latest effort to supply a much-felt want in the shape of an "Elektrotechnisches Wörterbuch, Englisch-Französisch-Deutsch," by the late Herr J. Sack, director of telegraphs, edited and supplemented by Herr Arthur Wilke, and published by Herr Oskar Leiner in Leipzig at the price of 4½ marks, or 4s. 6d. It is a creditable but somewhat irregular compilation, based in the main on Sloane's "Standard Electrical Dictionary," Houston's "Dictionary of Electrical Words, Terms, and Phrases," and Lefèvre's "Dictionnaire d'Electricité." We say "irregular," because, instead of each of the three divisions being complete in the three languages, the first section is English-German only, and the second French-German only, the third being perfect—German-English-French. This is a failing, however, which will more affect the British reader than the German term-hunter, for whom the volume is primarily intended. Herr Wilke cautiously estimates the yearly increase of electrical expressions in each language at "several dozen," and he mildly complains of the readiness with which the British, and especially the American, electrical engineer coins words in his profession. The editor is too much of a purist to insert the colloquial American "booster"—"Zusatzdynamo"—"supplementary dynamo"; but he thinks, in his preface, that the erstwhile slang word may become part and parcel of the Queen's English in good time. Of "dashpot" he gives the German equivalent in the dictionary as "Stossbremse," but he remarks that the English word is used by both German and French, just as we sometimes use the German "Drehstrom," without translating it into "rotary current." As to "trolley," again — German "Kontaktrolle" or "Laufrolle," French "poulie de contact"—Herr Wilke notes that in France it has recently become "trôlet," and he recommends "Trolle" to Germans, these two terms, it will be seen, practically preserving the pronunciation of our "trolley." It is, of course, always easy to pick holes in a work of this kind, but we cannot help noticing one or two inconsistencies. Why on earth, for example, in translating "air-gap," and "entrefer," its French equation, into German is the usual direct equivalent "Luftzwischenraum" not given instead of the encyclopædic "Zwischenraum zwischen der Feldmagnetpolfläche und dem Ankereisen einer Dynamo"—literally "space between the field-magnet pole surface and the armature core of a dynamo"? The consultation of ancient dictionaries is, moreover, evidenced by the spelling "oxyde." We do not, further, like the "swingings" of a magnetic needle, nor the "pik-up circuit," nor "rotatory currents," nor "redresser" (rectifier) given as the sole equivalent of "Gleichrichter"; nor "annunciator" for "indicator," nor the ambiguous treatment of the foreign representation of "cut-out" and "switch"; albeit, the new Leipzig work is, on the whole, a valuable one.

Edison on Patents.—Mr. Edison has recently communicated to a diligent interviewer some particulars as to the profits which he is alleged to have derived from his devices. "Considered purely as inventions," he is reported to have said, "they have cost me more than I have ever received from them. At least nine of my inventions have proved very profitable. These are the district telegraph system, the quadruplex system of telegraphy, the stock ticker, the telephone, the electric pen and mimeograph, the incandescent lighting system, the electric railroad, the phonograph, and the kinetograph. I claim one-half of the credit for the invention of the first, the third, and fourth of these, and the others are entirely my own work. I received very little for the district telegraph. I sold the quadruplex system of telegraphy for 30,000dol., and spent all of this sum, and more, trying to devise a plan to make a wire carry six messages instead of four. I failed, and so in the end was worse off than when I began. The stock ticker brought me at different times about 50,000dol., but it cost me more than that to perfect it. From the telephone I realised a clear profit of perhaps 25,000dol. Bell made less than half a million, though his father-in-law rolled up a vast fortune by securing control of large blocks of stock when it was selling for little or nothing. The profits of my electric pen

Digitized by Google

and mimeograph have been very small. The incandescent light has netted me 140,000dol.; it cost me nearly three times that sum to perfect it. I did not get my money back from the electric railway, which I sold out long ago, and I made nothing from the phonograph, which I have also sold. The kinetograph has not as yet returned me the original outlay. Our present patent laws, which, as interpreted by the courts, encourage perjury and put a premium on fraud, are worse than a farce, and I would have been a gainer if I had never taken out a patent. However, you must not think from this that I have not made money, but I have made it as a manufacturer and not as an inventor. My different inventions now furnish employment for 100,000 men, and this number is constantly increasing." "You speak somewhat harshly of the American patent laws," interjected the interviewer. "And with reason," broke in Mr. Edison with emphasis. "No sooner does an inventor make known some important mechanical discovery by applying for a patent, than a pirate comes along and steals it. Years pass before the case comes to trial, and in the meantime the practice of the courts gives the pirate the benefit of the doubt. Many patents are decided in the inventor's favour only when the patent is about to expire, and has therefore become almost worthless. This is all wrong. The courts should give the man who first secures a patent or first makes application for it the benefit of the doubt until the question of priority has been finally settled." Interrogated as to the general tendency of invention in the near future, Mr. Edison said that for many years to come inventions would deal in the main with securing greater economy of motive power. He added: "The turning of coal into motive power without the mediation of steam will be one of the next great triumphs of the inventor. I have for some years been at work on the problem of turning coal directly into electricity. I have clearly demonstrated that this can be done, and it now remains to be seen if it can be done at a profit. It would be a great thing if we could run a steamship or a locomotive engine for one-sixth of what it now costs, but I believe it can be done."

The Royal Society and Lord Kelvin.—The anniversary meeting of the Royal Society was held on Saturday last at Burlington House, W., when the president, Lord Kelvin, delivered the anniversary address. In the course of his remarks, he said that since the last anniversary meeting the Royal Society had lost 19 Fellows and seven foreign members. In Cayley they had lost one of the makers of mathematics, a poet in the true sense of the word, who made real for the world the ideas which his ever fertile imagination created for himself. He was the Senior Wrangler of his own freshman's year at Cambridge, and he himself well remembered to this day the admiration and awe with which, before the end of his first term, just 54 years ago, he had learned to regard Cayley's mathematical powers. When a little later he himself attained to the honour of knowing him personally, the awe was evaporated by the sunshine of his genial kindness; the admiration had remained unabated to this day, and Cayley's friendship had been one of the valued possessions of his life. At the good old age of 97 the veteran Franz Ernst Neumann had left them. He had been one of the most profound and fertile of all the workers in mathematical physics of the nineteenth century. Lord Kelvin then referred at length to the decease of Prof. Huxley and of M. Pasteur; and, in conclusion, he thanked all his colleagues of the Royal Society for electing him five times to be their president. In the evening the anniversary dinner of the Royal Society was held in the Hôtel Metropole, when the newly-elected president, Sir Joseph Lister, occupied the chair. A large and distinguished company sat down, the list of Fellows and guests present including the Italian Ambassador, the President of the Académie des Sciences, Lord Kelvin, Sir Gabriel Stokes, Mr. Ritchie (President of the Board of Trade), Sir D. Galton, Mr. Shaw Lefevre, the President of the Institution of Civil Engineers, Lord Rayleigh, Prof. Kennedy, Prof. Rücker, Prof. Ewing, Prof. Dewar, Prof. S. P. Thompson, Sir H. E. Roscoe, Prof. Roberts-Austen, Prof. Ramsay, Mr. Wolfe Barry, and Mr. Preece. Mr. Shaw Lefevre, in proposing the toast of the "Royal Society," said that in Lord Kelvin they had as president the greatest physicist of the day, and in his successor they had the greatest biologist of this country. Sir G. Stokes, in proposing the health of the retiring president, said that he knew Lord Kelvin very shortly after he took his degree at Cambridge, when they used to interchange ideas with one another on mathematical and physical subjects. He need not dwell on the eminence to which Lord Kelvin had now risen, but those who had the privilege of his acquaintance knew that it was not only for qualities of intellect that he was so remarkable, but also for qualities of heart. He hoped that now he was relieved from the cares of office, and enjoying the greater freedom that would come to him in the future, Lord Kelvin would continue to engage in the scientific researches with which he had been so long connected, and that he would yet be spared for many years to promote the cause of science in this country. In reply, Lord Kelvin said he was powerless to express his feelings after what Sir G. Stokes had said, and after the kind manner in which the toast had been received. He had now for more than 50 years looked upon Sir G. Stokes as his master in science. When an undergraduate at Cambridge, having himself some ideas on scientific investigation, his perpetual wonder was how Stokes chose to work on such infinitely difficult subjects. He could not understand the work he was doing. He could only admire; and still, whenever a difficulty occurred to him, it was to Sir G. Stokes that he must go for light and leading. To have succeeded Sir G. Stokes, and to have been president of the society for five years, was indeed the crowning honour of his life. Previous to this the medals of the society had been presented as follows: The Copley Medal to Prof. Karl Weierstrass, For. Mem. R.S. (received on his behalf by the foreign secretary), for his investigations in pure mathematics; a Royal Medal to Prof. James Alfred Ewing, F.R.S., for his investigations on magnetic induction in iron and other metals; a Royal Medal to Dr. John Murray, for his services to biological science and oceanography in connection with the "Challenger" reports, and for his original contributions to the same; and the Davy Medal to Prof. William Ramsay, F.R.S., for his share in the discovery of argon, and for his discoveries regarding gaseous constituents of terrestrial minerals. The following is a list of the officers and council elected for the ensuing year: President, Sir Joseph Lister, Bart., F.R.C.S., D.C.L.; treasurer, Sir John Evans, K.C.B., D.C.L., LL.D.; secretaries, Prof. Michael Foster, M.A., M.D., and Lord Rayleigh, M.A., D.C.L.; foreign secretary, Mr. Edward Frankland, D.C.L., LL.D; other members of the council: Mr. William Crookes, Sir Joseph Fayrer, K.C.S.I., Mr. Lazarus Fletcher, Mr. Walter Holbrook Gaskell, M.D., Mr. William Huggins, D.C.L., Lord Kelvin, Prof. Alexander B. W. Kennedy, LL.D., Prof. Horace Lamb, Prof. Edwin Ray Lankester, Prof. Charles Lapworth, LL.D., Major Percy Alexander MacMahon, R.A., Prof. John Henry Poynting, D.Sc., Prof. Arthur William Rücker, Mr. Osbert Salvin, Prof. Harry Marshall Ward, D.Sc., Admiral William James Lloyd Wharton, C.B.

SHREWSBURY ELECTRICITY WORKS.

Politicians with a certain trend of mind say Englishmen are, as rule, conservative. We prefer to think it really is so, and that the proletariat and socialist are importations rather than scions of the good old stock. Be this as it may, it is an undoubted fact that those who claim to be sons of England have a strange liking to read, hear, and think of their ancestors—to roam the streets and fields where history was made. Shrewsbury is one of those shrines with a most beautiful natural setting that lay claim to an historic renown which never fails in its appeal to the hearts of Englishmen. As far back as the time of Edward the Confessor, Scrobbes-byrig, or, as Domesday Book puts it, Sciropesberie, had 250 houses, with a resident burgess in each house, and five churches. This indicates that even in those remote times Shrewsbury was no mean city, and it played a great part in all the troublous times of English history from the reign of the Conqueror downwards. Here, again and again, before the final incorporation of Wales with England, the fierce and hardy Welshmen fought many a gallant fight. Many of the bloodiest conflicts of the Wars of the Roses and of the Civil War took place in this district, so that its position in history cannot be gainsaid. Then it was a centre of turmoil, now it is a centre of peace. Delightfully situated on the Severn, with its quaint and sometimes inconvenient streets, with its picturesque old houses, it has been just a little slow, so far as the local authority is concerned, in adopting the electric light. Its citizens, however, have shown their energy in patronising a private company to produce that which their councillors hesitate in doing. The electric lighting is consequently left in the hands of the Shropshire Electric Light and Power Company. This company was originally promoted by a few influential residents anxious to see electricity introduced into the town of Shrewsbury, and accordingly in the year 1891 the same was duly incorporated under the Companies' Acts, with power also to supply electricity to other towns in the county of Salop which might thereafter be selected.

The Corporation did not oppose the application of the company for a provisional order, which was accordingly granted to them by the Board of Trade. The area of supply under the provisional order includes "so much of the borough of Shrewsbury (Fig. 1) as lies on the north bank of the River Severn to the south and south-west of an imaginary line drawn from the north-west corner of the waterworks to Coton-hill, along Coton-hill to Cross-street, and along Cross-street to the point where the same is crossed by the bridge of the London and North-Western and Great Western Joint Railways, and thence to a point where the same river is crossed by the viaduct or railway bridge of the same railways, but excluding the railway stations, and so much of the borough of Shrewsbury as lies on the south bank of the River Severn, within a line drawn from the River Severn at the Boat House Inn to the Hanwood-road, and along the said road until it reaches Port-hill, and then down the lane from Port-hill to Rea Brook, and then along the said brook to the River Severn."

The compulsory area is much smaller, and is practically bounded by the ring of mains shown in the map. A more compact town—and hence a town more favourable to the adoption of the low-tension system—can hardly be found in the kingdom. The cost of the mains will therefore be relatively a small item compared with that in many towns, and it will be noticed that all the principal public buildings (shown in black on the map) lie closely around the supply station.

Gateway of Council-House, Shrewsbury, from the Courtyard.

Digitized by Google

The contract for the erection of the station, the supply of the necessary plant, mains, etc., was placed with Messrs. Edmundsons, Limited, of Great George-street, Westminster. The various sub-contractors under this firm are mentioned in connection with the apparatus they supplied. The company retained the services of Mr. A. H. Preece, A.M.I.C.E., to report on the plans drawn up by Messrs. Edmundsons, Limited, and afterwards to supervise the carrying out of the work. Now the station is completed and the work passed, Mr. Preece has presented a report to the company on the subject, of which we give the following abstracts:

"In the provisional order under which your company have all the necessary powers for the supply of electrical energy to Shrewsbury, the area specified as the compulsory area is most admirably situated for the first instalment of mains. It contains all the principal public buildings, hotels, shops, etc., and many other similar buildings are within easy reach. It is most essential to have a compact area, in order to prevent any large outlay of capital in copper mains. The money which has been spent in the mains, and which is the heaviest item in an electric lighting scheme of this kind, has been extremely moderate, yet it is fully able to comply with the demands of the compulsory area for some time to come.

MR. T. S. EYTON, CHAIRMAN, SHROPSHIRE ELECTRI LIGHT AND POWER CO

The system that you have adopted at Shrewsbury is that known as the low-pressure three-wire system. The two principal systems in use are the high pressure and the low pressure. There are many diverse opinions on the advantages and disadvantages of these two systems, but I always maintain that the question which decides the system is purely a local one. The most convenient position for the generating station and the area to be lighted are the two essential points. I consider that your directors have been very wise in adopting the low-pressure continuous-current system. It is undoubtedly the best system for Shrewsbury. It will be, of course, an easy task to generate currents of higher pressure when it becomes necessary to serve districts lying some distance away.

"The great advantages of this low-pressure system are: (1) the use of accumulators, which enables the generating plant to be run only in the evening—that is, at times of heavy demand—and which also form a reserve in case of a breakdown in the generating plant; (2) the safety of the low-pressure current; (3) the adaptability of the continuous current for use in driving electric motors; (4) the great economy in production.

"*Prospects.*—I feel very confident that the electric lighting scheme at Shrewsbury will be most successful. There are already over 1,000 lamps connected and applied for. Shrewsbury is a town with plenty of trade. There are many excellent shops and hotels, large public buildings, and good private houses. The success of electric lighting in other towns is certain to be followed by Shrewsbury. The great point is to keep the capital expenditure at a minimum and to get most out of the generating plant, and especially out of the mains. I see

MR. W. W. NAUNTON SECRETARY TO THE COMPANY.

no reason why this cannot be done at Shrewsbury. The present capital expenditure is small, and the area already served by the mains is the best and most compact that any town could have. The population of Shrewsbury is some 27,000. There are already towns of this size which have established electric lighting installations, and which are a great success. I feel convinced that as soon as you are able to obtain 4,000 lamps connected to the mains, a good profit will be made on the capital expenditure."

MR. J. C. WIGHAM, RESIDENT ENGINEER.

Mr. Preece's report also contains a short description of the plant, which, together with the figures as to probable cost, etc., we have been compelled to leave out.

The generating station is situated in Eagle Foundry-square, which, in addition to a foot approach through a passage leading from Pride-hill, known as "Seventy Steps," possesses also the advantage of an entry to the works by a convenient level roadway direct from the railway depôt for

Digitized by Google

delivery of coal, removal of refuse, etc. The approach down the Seventy Steps is quite a feature in the characteristics of Shrewsbury. A small alley which would be taken for a private passage leads to the head of 70 precipitous steps down the hillside, which will afford a good test as to the sobriety of the staff generally. The buildings were designed by and erected under the superintendence of Mr. A. E. Lloyd Oswell, architect, of Shrewsbury, the contract for the same being entrusted to Mr. Henry Price, builder, of Welsh Bridge, and consist of boiler-house, engine-house, battery-house, offices, stores, and chimney stack 132ft. high. Some difficulty was experienced in obtaining satisfactory foundations for the latter, as, after excavating some 23ft. down through loose material, water was struck, which threatened to stop the work. It was, however, kept under by means of a steam-pump working night and day. Some 3ft. lower a shelving rock was found which would support the chimney on the

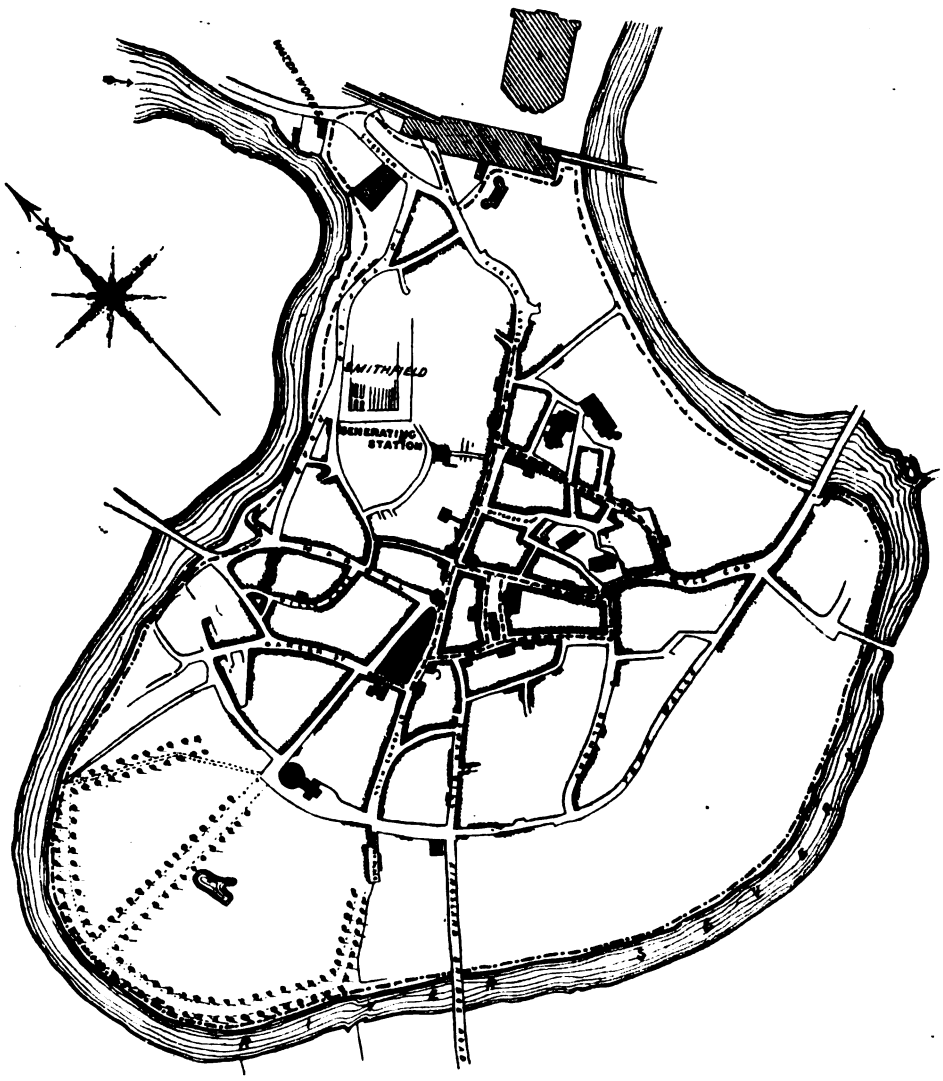

FIG. 1.—Map of Shrewsbury, showing Mains, etc. — · — · — · — denotes Main, and ● a Feeding Point.

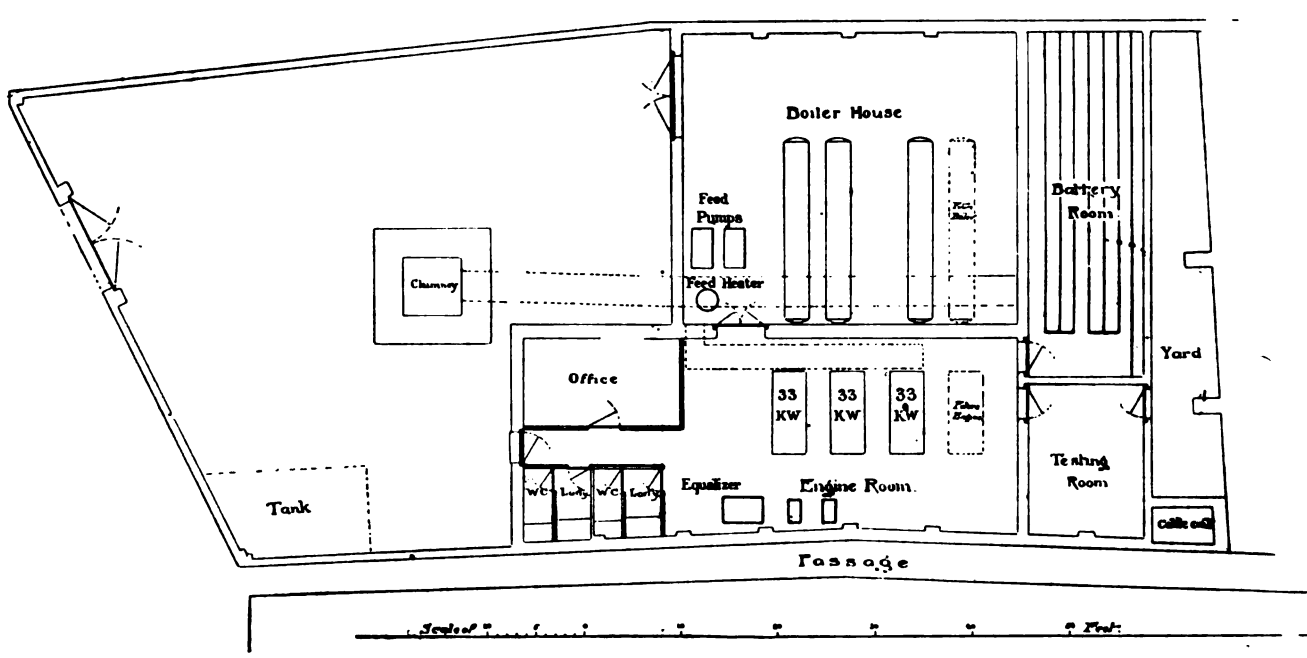

FIG. 2.—Plan of the Shrewsbury Electric Light Station, showing General Arrangement of Plant.

Digitized by Google

inside. As the rock did not extend towards the river, it was decided to pile that side of the site. A 5ft. layer of cement concrete was then laid down over the pile heads and mortised into the rock, and on this the stack was built. The actual height of it from the concrete foundation is 132ft., but only 110ft. of this is above the entrance of the boiler flue. The shaft is 5ft. square inside throughout its entire height. The present buildings are designed to accommodate without alteration sufficient plant to supply 5,000 8-c.p. lamps simultaneously.

The general arrangement of the station and plant is shown in Fig. 2, the various machinery being indicated diagrammatically.

Steam Generating Plant.

The whole of this has been supplied by Messrs. Babcock and Wilcox, Limited. Three of their tubular boilers are at present fixed, each having 593 square feet of heating surface, two of the boilers being set together in one battery.

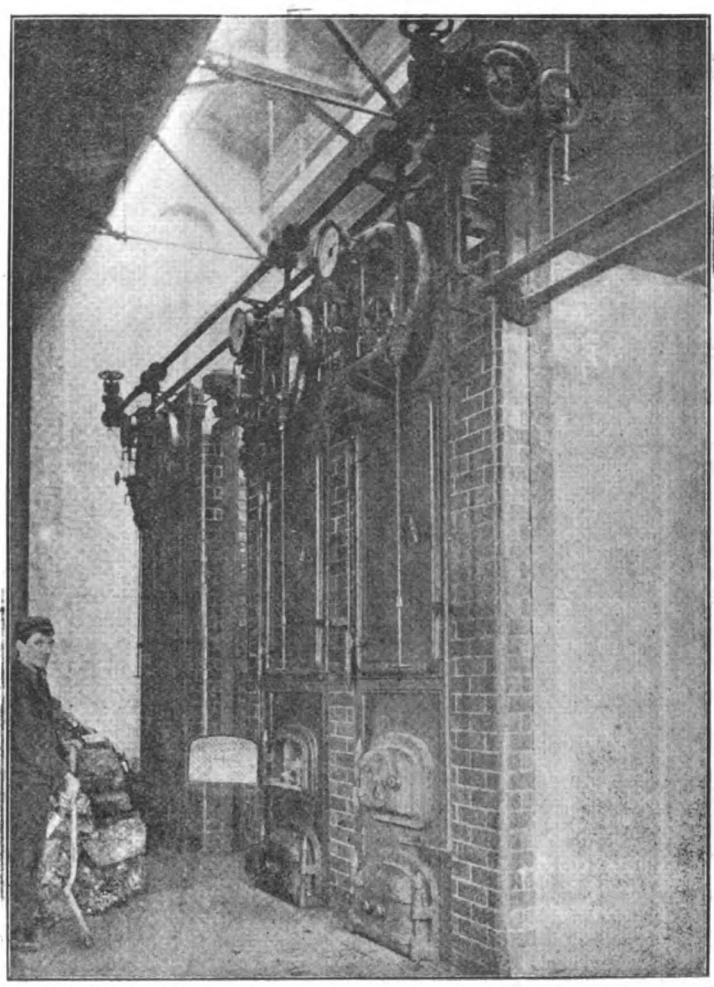

Fig 3.—View of the Boiler-House.

The remaining one is set by itself (Fig. 3), but is so arranged that a fourth boiler can be added at any time required. Each boiler is composed of four sections of tubes, each section being made of eight tubes 14in. long and 4in. in diameter. The steam and water drum is 30in. diameter and 19ft. 2in. long. It is fitted with Turnbull's dead-weight safety-valve, two angle feed-valves with long spindles, large main steam stop-valve, and the necessary blow-off cock, combined feed and check valve, water-gauges, etc. The manhole is arranged in the boiler shell, and the blow-off pipe is bent so as to come 6in. below the floor level. Each boiler works at 120lb. per square inch, and was tested after erection to 200lb. per square inch. There are two Worthington feed pumps 4½in. × 2¾in. × 4in., and the steam-mains to them are so constructed that steam can be taken from any one boiler should the others be standing. The pumps can each supply 5,400lb. of water per hour to the boilers.

The feed water, which is taken from the town supply, is passed through an exhaust feed-heater, also manufactured by Messrs. Babcock and Wilcox, Limited. This heater (Fig. 4) is designed on the water-tube principle, similar to the boilers; all the tubes are perfectly accessible for cleaning and inspection by merely removing the covers at the top and bottom of the heater, and as the tubes are straight they are readily cleaned by means of tube brushes and scrapers. Moreover, as the feed water enters at the top of the heater and leaves at the bottom the tendency is for any impurities in the water—such as dirt, or the carbonates and sulphates of lime and magnesia, which become insoluble when water is heated—to pass with the current of water into the bottom chamber, from which they are readily blown off by means of the cock fitted for that purpose. The construction of the heater tends greatly to prevent the adhesion of scale to the sides of the tubes. The heater is provided with a by-pass pipe, by which the exhaust steam can be taken direct to the atmosphere, if desired, instead of passing through the heater. The heater casing is only of light construction, as it has only to withstand the pressure of the exhaust steam, whilst the area allowed for the passage of the exhaust steam around the tubes is considerably greater than the area of the exhaust-pipe, which effectually prevents any back pressure being thrown upon the engine, a fault which is common in types of heaters in which steam is passed through the tubes instead of around them. The tubes are expanded into heavy mild-steel end-plates, and should a new tube at any time be required it can easily be inserted and expanded by any ordinary mechanic. There are 36 of these brass tubes, each 1½in. diameter and 5ft. 11in. long, giving a total heating surface of 84 square feet. This feed-water heater is capable of heating from 5,000lb. to 5,500lb of water per hour up to about 200deg. F. A duplicate system of feed-water mains is supplied to connect the two pumps with the boilers. These mains are taken overhead (Fig. 3),

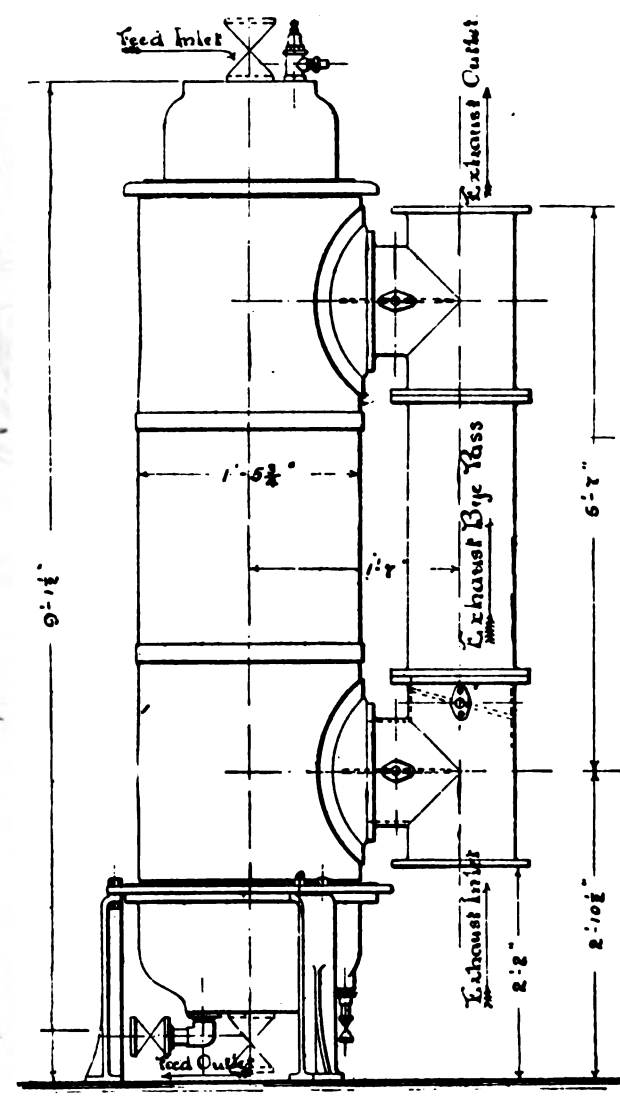

Fig 4.—The Babcock-Wilcox Exhaust Steam Feed Water Heater.

Digitized by Google

and are arranged so that any boiler can be fed through either main by either pump, and that the water can either be passed through the heater or be fed direct into the boilers.

Steam and Exhaust Pipes.

These were included in the same sub-contract. The steam-pipes are arranged on the ring principle, the main being 4in. diameter. All the pipes are of wrought steel, with welded seams and wrought-steel flanges welded on. The T-pieces and pocket pipes, which can be seen in Fig. 5, are cast with a specially strong mixture of cast iron. The pocket pipes and the stop-valves on the engines are connected by the necessary drain-pipes to a Geipel steam-trap. The joints between the various pipes are made with corrugated brass rings. The exhaust-pipe is of cast iron, 8in. diameter, and connects the three engines with the feed-water heater. A by-pass valve is also arranged so that the steam can be discharged direct into a pipe in the chimney if required. The exhaust-pipe is laid in a trench round the foundations of the engines, the trenches being covered with wrought-iron chequer plates. The steam-pipe is suspended on long rods, so that it is free to expand. No condensing plant is provided at present, but when the station is extended it will be quite possible to obtain a good supply of water by sinking a well on the site. The parts of the steam-drum exposed to the atmosphere are lagged with a non-conducting composition 2in. thick, as are also the main steam-pipes, the steam to the pumps, and the feed-delivery pipes from the heater to the boilers.

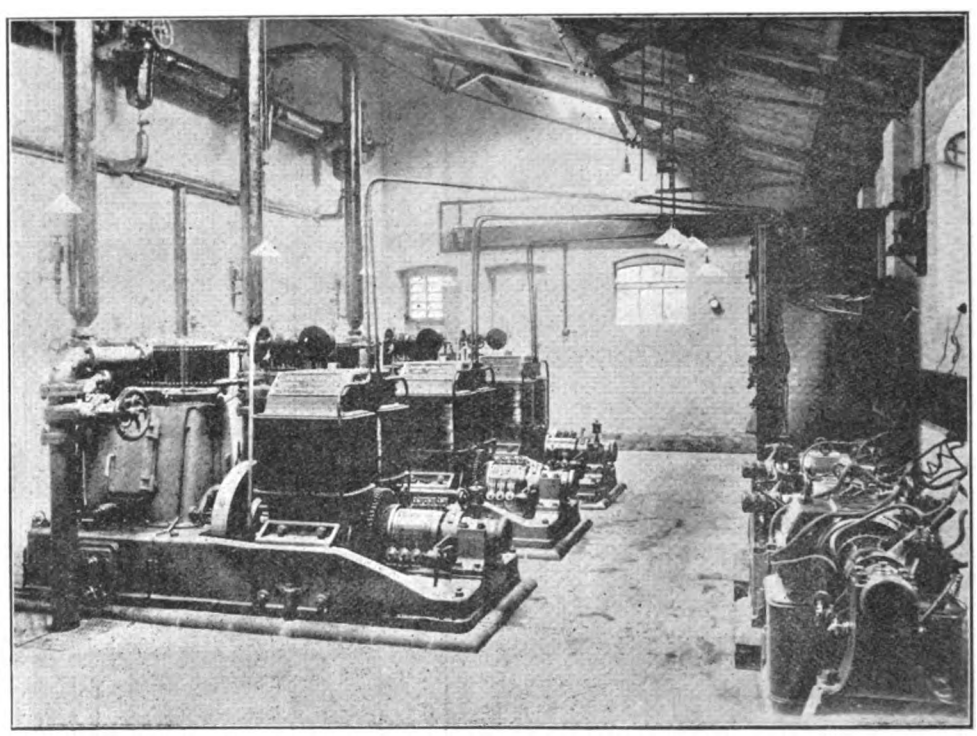

Fig. 5.—General View of the Engine-Room.

Engines.

These have been supplied by Messrs. G. E. Belliss and Co., of Birmingham. The engines are three in number, designed for an output of 49 b.h.p., at a speed of 500 revolutions, with steam pressure of 120lb. per square inch at the engine stop-valve. These engines are of the single-eccentric type of the closed-in type. The eccentric is placed between the two cylinders, and works both the high and low pressure valves, which are of the cylindrical type. The oil is supplied by means of a simple pump, without valves or packing, working off the eccentric from a well in the framing, and discharging at a pressure of about 10lb. through oil-channels into all working parts. The double action of the engine permits the film of oil, at this pressure, to get thoroughly between the working journals and brasses, keeping them apart and preventing any wear or chance of knocking with any load. The casing is fitted with a hinged door at back, to allow of free access for inspection and adjustment, and the whole front of the casing can be removed in a few minutes, if necessary, to overhaul the working parts.

The governors are well designed, and hold the engines in control in spite of sudden fluctuations of load, the increase of speed when the whole of the load is suddenly thrown off being only 3 per cent. Hand adjustment of the governors is, however, provided, which allows of a 15 per cent. variation of speed. This conduces to economy at light loads, as the speed can be reduced. Fig. 6 shows one of these engines coupled direct to a dynamo.

Electrical Machinery.

The sub-contract for this part of the outfit of the station was placed with Thomas Parker, Limited. There are three shunt-wound dynamos direct coupled to the Belliss engines. Each machine is capable of giving 150 amperes at 220 volts when running at 500 revolutions. The dynamos are drum wound with the patent Eickemeyer system, so largely used by Mr. Parker. The field magnets are of cast steel, the two limbs and yoke being one casting. This casting, however, terminates on the horizontal plane through the axis of the armature. The two other portions of the pole-pieces are separately attached to the brass supports, so that all the upper portions of the field-magnets with the shunt windings can be lifted off, leaving the armature exposed *in situ*. Sight-feed lubricators are used on these machines. The equaliser is connected across the two outside wires of the three-wire distribution to balance any excess current that may occur on either side. It consists of a duplex armature running in the ordinary type of field magnets. The number of turns in the two armature windings is the same, and each winding will stand 80 amperes at the pressure of 110 volts. The machine is provided with ring lubricator. The other two machines near the equaliser, shown diagrammatically in the plan, Fig. 2, and which can also be seen in Fig. 5, are "boosters" for providing the excess voltage required to charge the accumulators. They are constant-current transformers of the same general type as the equaliser, but the number of turns in the two windings on the armature have the ratio of 110 to 35. So the voltage is reduced in this ratio, and the 35 volts obtained by transformation are connected in series with the normal supply to charge the accumulators. There are two of these boosters—one for each set of accumulators. They run at about 1,000 revolutions per minute when fully loaded. The E.M.F. and charging

Digitized by Google

current are regulated by a resistance in the primary circuit.

SWITCHBOARD.

The switchboard (Fig. 7) and all connections to it are also supplied by the above firm. The switchboard consists of eight panels of slate mounted on strong wood frames. Of these are three dynamo panels each fitted with an ammeter, a double-pole switch and fuse, and a 17-way switch and resistances for regulating E.M.F. of dynamos by varying the shunt current; two accumulator panels each fitted with an ammeter for charge and discharge circuit, two single-pole switches, a 12-way battery regulating switch, and starting and regulating switch with resistances for use with the charging transformer; one balancing transformer panel fitted with a double-pole switch, a transformer starting switch with resistances, and two registering ammeters which record the total output of the station; two feeder panels fitted with ammeters and fuses for four feeders."

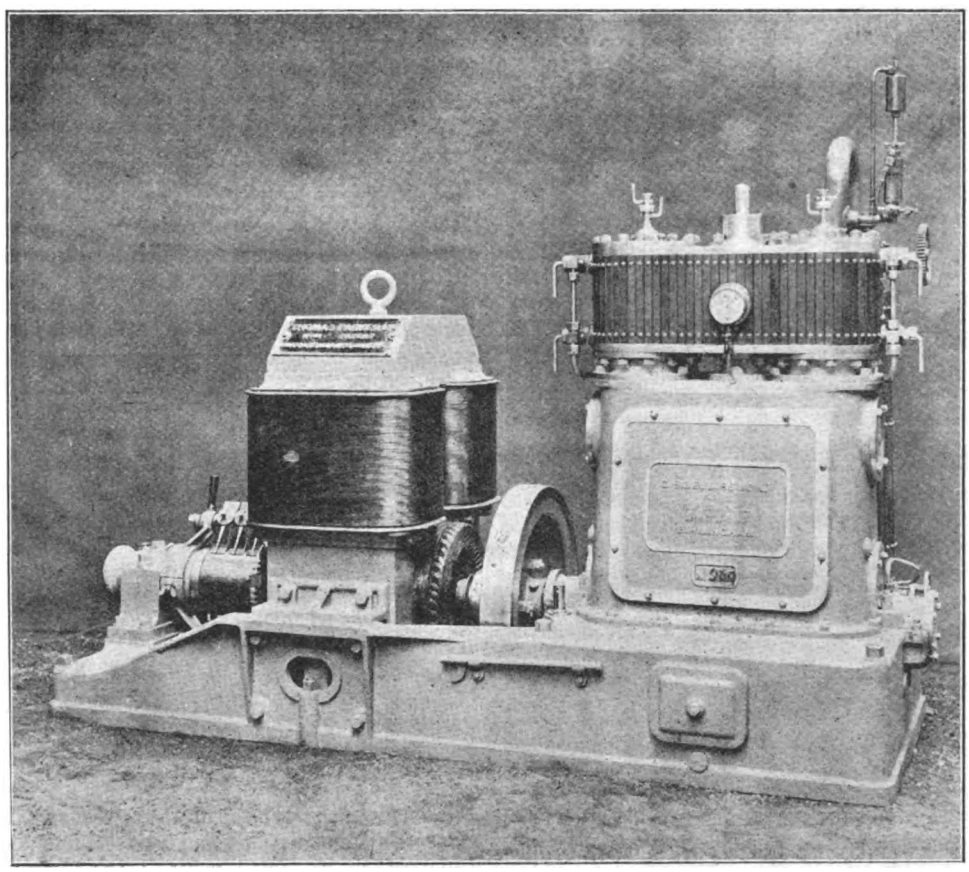

FIG. —The Bellias-Parker 33-K.W. Steam Dynamo.

METHOD OF WORKING.

All the 220-volt dynamos are coupled in parallel on to omnibus bars, from which the outside wires of the feeders take their supply of current. The centre wire of each feeder is brought back to a centre terminal in between the two armatures of balancing transformer and to the centre of the battery of accumulator battery, so that either the balancing transformer or the battery may be used for

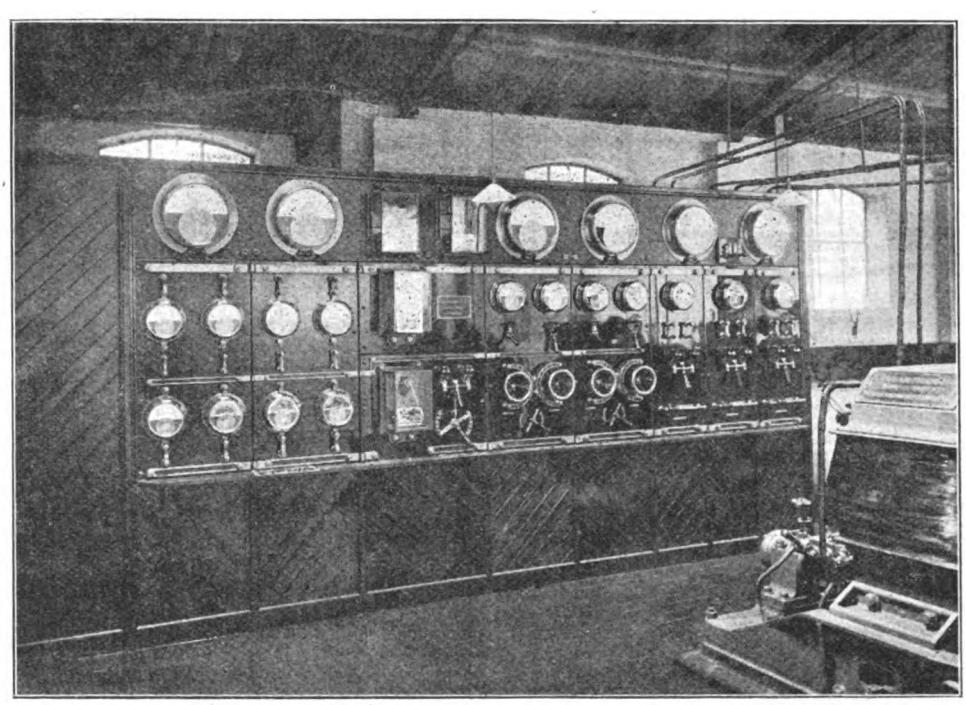

FIG. 7.—The Switchboard at the Shrewsbury Electric Light Station.

Digitized by Google

supplying the excess current to balance the two sides of network. The batteries are charged as far as possible directly across the omnibus bars, the charging transformers being used for the latter portion of the charging only.

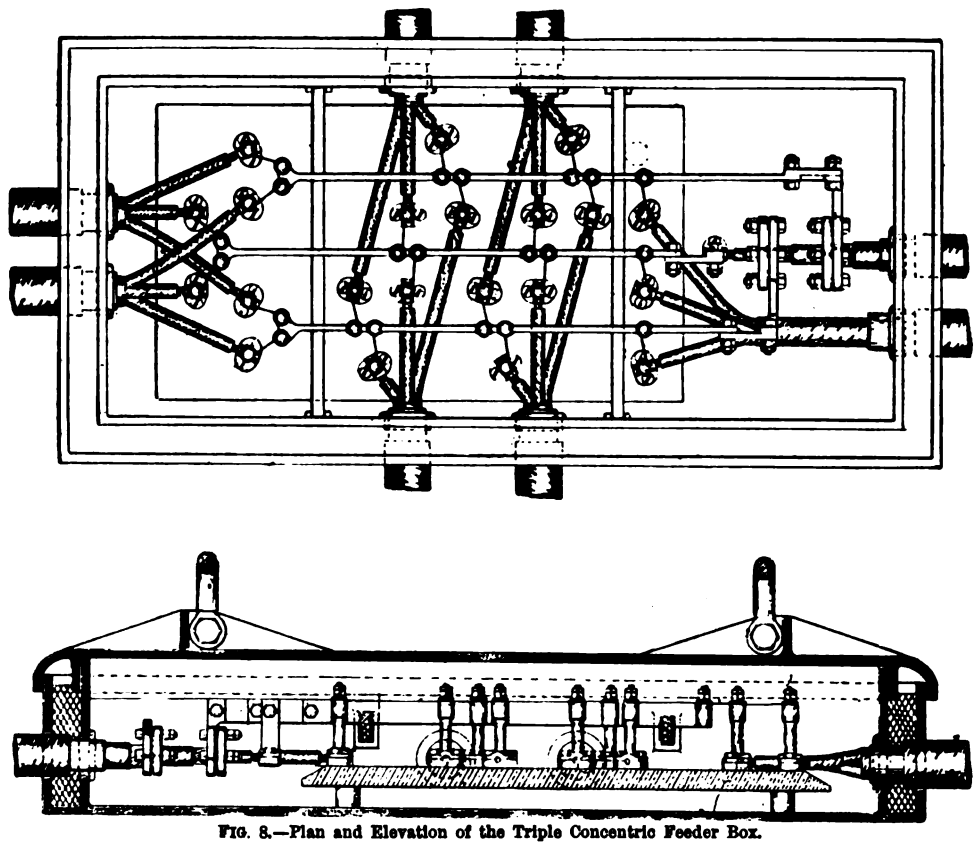

FIG. 8.—Plan and Elevation of the Triple Concentric Feeder Box.

ACCUMULATORS.

These are of the well-known D.P. type, and are supplied by the D.P. Battery Company. There are 110 cells, each containing 19 plates. These are connected all in series, the centre connection being made to the zero wire of the network. The capacity of battery is 500 ampere-hours.

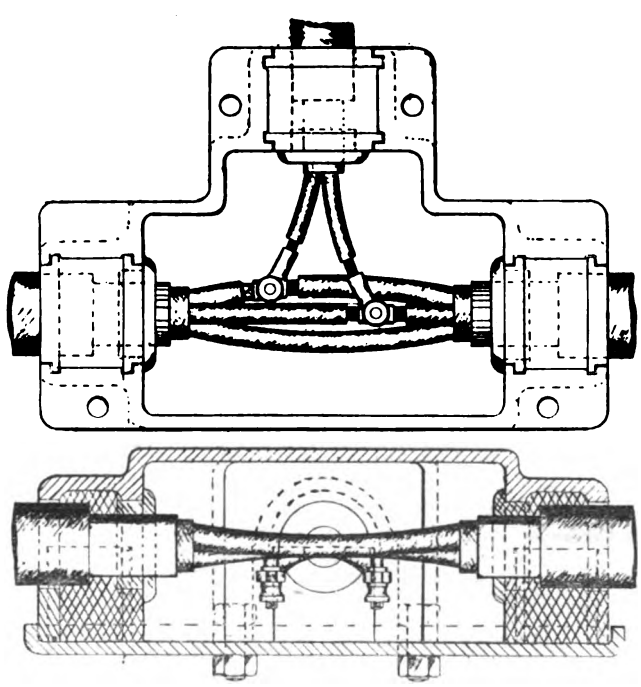

FIG. 9.—Plan and Elevation of House Service Box.

The cells are arranged in five rows on the floor of the battery-room, so that additional batteries can be arranged above them when required.

MAINS.

The whole of the cables which have been used in connection with the Shrewsbury lighting were manufactured by the Callender Bitumen Telegraph and Waterproof Company, Limited, of London and Erith, and laid by them under the charge of their resident engineer, Mr. A. Burton. The Callender Company undertook the whole of the street work, making all the necessary excavations and reinstatement of the roads and footpaths. In some parts of the town this was a work of considerable difficulty, especially at Seventy Steps, where great precautions had to be taken to prevent damage to existing buildings, many of which are very old. The whole of the cables are laid on the three-wire system, those used as distributors being of a special type. They consist of three conductors, each separately insulated and then stranded together, packed to a circular section, lead sheathed, and armoured. The feeder cables are of the ordinary make of triple concentric, the dielectric in each case consisting of bitumenised fibre, but the lead sheath which has been used is of an exceptionally heavy type.

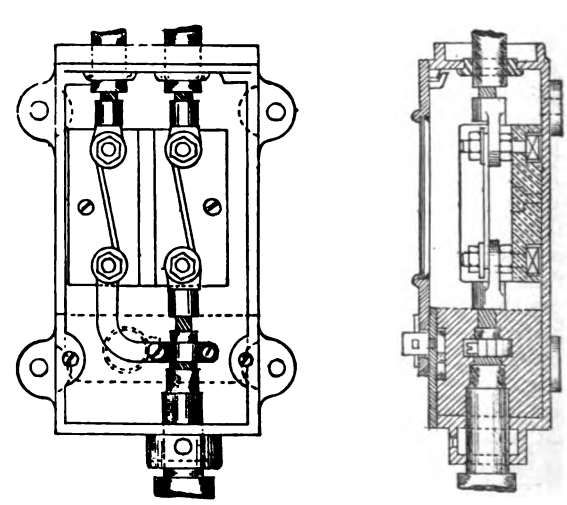

FIG. 10.—House Connection and Fuse Box.

The greater part of the distributors are of ·06 square inch sectional area, but in outlying streets a smaller size has been used, each conductor being ·035 sectional area. In some of the heavy portions of the town the size of the distributors has been increased to ·100 square inch section. The total amount of distributors now laid is over 2,500 yards.

Digitized by Google

Five feeder cables are carried from the distributing station to the top of Seventy Steps; two of them at present end there, so as to be suitable for future extensions. The other three are carried to different points in the town, and are connected to the network, at the points shown in Fig. 1, by means of boxes, as shown in Fig. 8. It will be noticed that fuses are provided, so that in the event of any line becoming overloaded by a fault, either at the consumer's premises or on the mains themselves, it would be cut out of service. The space round the box through which the cables enter is cast in with bitumen to secure the cables in position. Then, after all the connections have been made, the box is filled up with a special compound till only the fuses project. This securely seals all the cable ends, and gives a good insulation to the system. Each of these boxes is set in a brick-built pit, which is closed by a cast-iron frame having a concrete cover. The boxes have been very strongly constructed. The consumers are connected with the mains by means of a service box, shown in Fig. 9. At the end of each consumer's line a fuse-box of the type shown in Fig. 10 is fitted. These fuse-boxes are fireproof, and are designed to meet the requirements which have now been insisted upon at the recent conference held by the Board of Trade at Westminster. The capacity of the feeders and mains at present laid down and connected are sufficient for 3,000 8-c.p. lamps burning at one time, or, say, 5,000 fixed in consumers' premises.

Mr. Preece, in his report speaking of this part of the work, says: "The whole of the mains have been laid down under my supervision, and have been thoroughly tested by me. They are fully up to the highest standard for this kind of work."

The opening ceremony takes place on Tuesday, the 10th inst., under the presidency of the Mayor of Shrewsbury. To popularise the light an electrical exhibition has been arranged, and will be opened by Mr. W. H. Preece, F.R.S., C.B.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE BOARD'S PROPOSED REGULATION ON TESTING ELECTRIC SUPPLY SYSTEMS.

SIR,—Major-General Webber in your issue of last week amplifies the criticism he made at the Board of Trade conference with respect to Rule 10, which provides for periodical insulation tests of every complete circuit used for the supply of energy, and he assumes "want of experience" on the part of those, who like myself, supported the proposed rule. I cannot help thinking that General Webber has failed to realise the object of the rule or the advantages to be gained by its observance.

If it be assumed that defective insulation may be a source of danger, either to the public or to the maintenance of an efficient service, it surely must be obvious to anyone with any practical experience of central-station work that it is quite immaterial whether the defect is on that part of the circuit belonging to the undertakers or on that part belonging to the consumer. The test that is required is the test of the *complete circuit*, as proposed by the Board of Trade and supported by Mr. Preece at the conference.

As the result of many years of central-station work in Liverpool we have long since adopted for our own protection *hourly* tests of the insulation resistance of the complete circuits supplied from each of our stations. These tests generally show an insulation very much higher than that prescribed by the Board of Trade rule, which limits the leakage to one-thousandth part of the maximum supply current. If the hourly test of the whole of the connected circuits shows any failure of insulation, we are able by a special device to trace which of the individual circuits supplied from the station is faulty.

The above tests are made without any disconnection of mains or interruption of supply, but when a faulty circuit has been detected in this way it is, of course, necessary to examine it in detail to ascertain whether the fault exists on any portion of the company's mains, or, as is more frequently the case, on the consumers' premises, and this part of the work is carried out at such hours of the day or night as may cause least inconvenience to the consumers affected. Insulation tests limited to the undertakers' portion of the circuit, as suggested by General Webber, would be practically useless for the purpose intended. In Liverpool, all mains have an insulating covering throughout, but in Birmingham, where exactly the same system of testing is adopted, the mains include a considerable length of bare copper conductor.

My chief object in troubling you with this communication is to express the hope that the great consideration and courtesy shown by Sir Courtenay Boyle and his advisers to those interested in the supply of electrical energy will be appreciated by engineers responsible for supply stations, and that they will support the Board of Trade in making such rules as are calculated to secure real efficiency.—Yours, etc., A. BROMLEY HOLMES.

THE LIGHTING OF RAILWAY CARRIAGES.

SIR,—We have read with interest the article in the current number of your journal of our new system for the electric lighting of railway carriages. We would point out to you, however, that your remarks concerning waste of power due to the slipping of our driving belt do not at all agree with the results of our practical experience. We shall be pleased if you will call at our works in the course of the next few days, when we will practically demonstrate to you that the figures you gave with regard to this matter were based on a misconception. We shall also be pleased to afford you a more convenient opportunity for fully inspecting our apparatus than could be given at the trial run last week.—Yours, etc., J. STONE AND CO.

[We shall be most pleased to accept Messrs. Stone and Co.'s invitation to investigate this most interesting subject.—ED. *E. E.*]

(For remainder of Correspondence see page 655.)

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

December 10, 8 p.m.—Ordinary meeting. Discussion on the papers by Messrs. Arnold and Wrightson on "The Physical Properties of Iron and Steel."

Physical Society.

December 13—1. "A Mechanical Device for Performing the Temperature Corrections of Barometers," by Dr. John Shield. 2 "On the Existence of Earth-Air Electrical Currents," by Prof. Rücker, F.R.S.

Institution of Electrical Engineers.

December 12, 8 p.m.—At 25, Great George-street, Westminster. Annual general meeting. Also discussion on "The Electric Wiring Question," paper by F. Bathurst; and on "Concentric Wiring," paper by Saml. Mavor.

Society of Arts.

December 9, 8 p.m.—Cantor Lectures, "Mechanical Road Carriages," by W. Worby Beaumont, M.I.C.E. Lecture II.

December 11, 8 p.m.—Fourth ordinary meeting. Adjourned discussion on Mr. Cunynghame's paper on "Locomotive Carriages for Common Roads."

Northern Society of Electrical Engineers.

December 9.—At the Palatine Hotel, Hunt's Bank, Manchester. Council meeting at 7.15 p.m.; annual general meeting at 8 p.m. Election of council and officers. "Test of a Colliery Hauling, Pumping, and Lighting Installation," by C. H. Lees, D.Sc., Owens College.

Chesterfield and Midland Counties Institution of Engineers.

December 7, at 3 p.m.—At University College, Nottingham, General meeting. The following papers will be read or taken as read: "Fencing Gates for Winding Shafts," by William Hay; "A Boring below the Blackshale Coal at Apperknowle, near Sheffield," by G. E. Coke. The following papers will be open for discussion: 1894.—"Report of the Flameless Explosives Committee of the North of England Institute: Part I., Air and Combustible Gases," by A. C. Kayll (adjourned from Leicester meeting, January 26, 1895). December, 1894.—"An Underground Endless Rope at the Moston Colliery, Manchester," by H. Richardson Hewitt (adjourned from Nottingham meeting, March 16, 1895). March, 1895.—"Banking, Screening, and Mechanical Arrangement for Direct Sorting and Packing Coal,' by William Hay (adjourned from Nottingham meeting, March 16, 1895). July, 1895.—"Photometric Value of, and Notes upon, Various Illuminants Used in Mines," by A. H. Stokes (adjourned from Chesterfield meeting, October 12, 1895).

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THAT MUNICIPAL ENGINEERS' SOCIETY.

It is with regret we find the acting spirits in the formation of this society have not yet learned wisdom. They still insist upon electing as honorary secretary a man outside their own body—and connected therewith simply as a business man to sell them goods. This act will be absolutely fatal to the success of any such society, and will have the effect, instead of raising the position of electrical municipal engineers to the level of gasworks managers or waterworks engineers, of degrading them to the position of those who play into the hands of salesmen. It is no use mincing words. Business men do not undertake secretarial work of this kind for nothing. It is impossible to imagine the waterworks engineers—who, by the way, are also about to form an association, the first meeting of which will be called at Nottingham early in January—electing a man as secretary—call him honorary or otherwise—whose aim in life is to sell them goods. What has a commercial traveller to do with the inner working of municipal engineering? No doubt his place is to know and be on friendly terms with every electrical engineer, but it is not, therefore, their place to make him their confidant. From what we have heard on the subject, we feel certain that the majority of municipal electrical engineers will repudiate the course of action taken at what must be designated a hole-and-corner meeting during the late conference. The notices for this meeting were sent out in such a manner that the greater part of the municipal electrical engineers' body had no opportunity of being present at the meeting in order to declare their opposition to such action. It rests with municipal electrical engineers to make their own position, and if they prostitute themselves into the hands of commercial travellers they must expect to be treated with scant respect. Regretting a mistake made in initial periods of action in future years will not mend matters. The time to take every precaution and to guard against every appearance of commercial trafficking is at these early stages. The going outside their own body to obtain a secretary is not the point in question; the error is in the selection of a commercial man with whom they must have business relations, and having them, any action of playing into his hands is likely to be misconstrued. We have no hesitation in saying that the commercial man's sole aim is self, and he would not be a good business man were it not so. Hence, as the real acting head of a society the aim of which is not buying and selling, he is out of place.

THE INSTITUTION.

The balloting list for the Council and officers for the year 1896 has reached us, and is given in another column. It will at once be noticed that the Council have avoided joining issue with the organised opposition against placing the senior vice-president in the presidential chair. We have purposely refrained from referring to the matter in our columns up to the present. We hold that the candidate for the highest honour the Institution can bestow should be held in such esteem by the general members as

Digitized by Google

to render the ballot a complimentary form. If, however, a gentleman is proposed who does not meet with general approval, the opinion against him should, in our opinion, be expressed at the ballot only. The opposition should only direct its aims to arranging that all adverse votes are placed in one direction only. The agitation which has been everywhere felt on the subject during the past month can only bring discredit on the profession as a whole. We cannot, therefore, regard the present list with satisfaction, because it practically assumes that the whole matter will again be brought forward at the annual meeting in 1896. The rearrangement of the vice-president list is also unsatisfactory, as we find the gentleman who certainly best represented the general engineering side has been unceremoniously struck off to make room for another representative of the professional class, which already carries undue weight on the Council. We would wish rather to see the importance of central-station engineers more acknowledged by the inclusion of at least one more of their number on the Council.

THE PRESIDENTIAL ELECTION.

SIR,—A committee, of which we were invited to act as honorary secretaries, was recently formed of the members of the Institution, representative of all sections of the industry, to give effect to the views of a large number of members and associates on the subject of the forthcoming election of president. It was considered that in the interests of the Institution the president should be a man pre-eminent in electrical science or electrical engineering, and that the presidency should not necessarily be a matter of rotation among the vice-presidents.

The balloting list issued by the Council for the year 1896, which is now in the hands of the members and associates, indicates that the Council, in nominating Dr. John Hopkinson for election as president, share the same views. It is believed that in abandoning an undesirable custom, the Council have acted in sympathy with the general wishes of members of all classes, and that the selection of Dr. Hopkinson will meet with the unanimous approval of the Institution.—Yours, etc.,

R. S. ERSKINE
A. A. C. SWINTON } Hon. Secretaries.

December 4, 1895.

COUPLING DYNAMOS IN PARALLEL.

SIR,—I would feel much obliged by your informing me, through your columns, if it is permissible to join up in parallel a shunt-wound dynamo (130 volts 120 amperes) and a compound dynamo (110 volts 275 amperes) to feed one circuit; also what would be the result of this combination with regard to mutual effect, etc., each machine being speeded properly?—Yours, etc. REACTION.

[With reasonable care in working, there is no objection to the coupling of a compound dynamo in parallel with a shunt provided the circuit to be fed is not subject to very large and sudden changes of load. The danger is that the shunt machine may overpower the compound at light loads and demagnetise the field. Without information as to the method of driving the above machines and the voltage required from them in parallel, it is impossible to answer the last part of the letter. In any case the distribution of the load between the two will have to be effected by hand adjustment.—ED. *E. E.*]

Erratum.—In the letter from M. Jean Rey on the "Qualities of Mangin and Parabolic Mirrors," printed in our issue of November 22, p. 581, there is a slight misprint. In the second column, p. 581, just above the diagram, for I/e read I/e^2.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XVIII.

(Specially Contributed.)

Post Office Pattern.—In the various illustrations the long light pointer must not be confused with the short needle. The needle must be kept short in order that it may be wholly in a uniform field, and, again, that its motions may not take it out of a uniform field, but most instruments are in some way furnished with long light pointers to assist the scale reading. Fig. 1 shows a plan of the

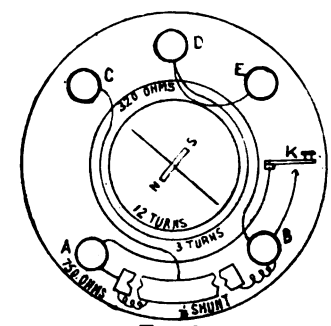

FIG. 1.

latest Post Office pattern of tangent galvanometer. Around the needle are really three coils—one of only three turns of wire of No. 18 gauge—*i.e.*, of 48 mils diameter—one of 12 turns of similar wire, and a third with a resistance of 320 ohms. The three turns end in the terminals C D, the 12 turns wound in the opposite direction end in the terminals D E. In addition to the coils of 320 ohms between the terminals A B, there is a resistance external to the galvanometer coil of 750 ohms, which can be used or not, as required by the test. There is also a shunt coil of one-tenth to the high-resistance coil. Let us consider the effects of these various coils. Schweiger showed that the influence of one wire was doubled by duplicating the coil and tripled by triplicating the coil, of course current remaining constant. Suppose, then, we are dealing with a current, C,

Call the effect of one coil {carrying current, C, round the magnet} x,
then " " two coils each " " will be $2x$,
and " " three " " " " " $3x$,
" " " twelve " " " " " $12x$.

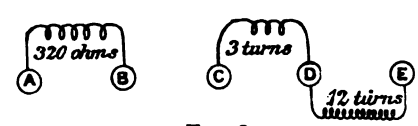

FIG. 2.

Perhaps the diagram, Fig. 2, will help us.

(1) If the conductor carrying current is connected between C D its effect will be $3x$.

(2) If it be connected between D E its effect will be $12x$, but the needle will move in the opposite direction to that it moved in case 1.

(3) If it be connected between C E we oppose three turns to the twelve turns, and so get $12-3=9$ effective turns, or an effect of $9x$.

(4) Alter the diagram a little, as in Fig. 3.

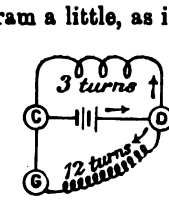

FIG. 3.—("G" on diagram should be "E.")

Join C E by a conductor whose resistance may be negligible.

We have a complete circuit.

Now put our current-carrying conductor between C D.

The current gets to D, splits up there to go by the two paths—viz., the three-coil path and the 12 coil path—and it splits up inversely as the resistance—that is, the biggest

Digitized by Google

part goes by the line of least resistance, and the smallest part by the line of greatest resistance. Representing the total C by 15, then

12 parts out of the 15 parts will go by the 3 x coils,
and 3 „ „ „ „ „ „ 12 x coils.

That is $\frac{12}{15}$, or $\frac{4}{5}$ of the current goes by the 3 coils,
and $\frac{3}{15}$ „ $\frac{1}{5}$ „ „ „ „ 12 coils.

In this case the effect of the three-coil branch will be—
as $\frac{4}{5}$ C goes through each coil,
the effect of three coils on needle will be $3 \times \frac{4}{5} = \frac{12}{5}$ C;
as $\frac{1}{5}$ C goes through each of the 12-coil coils,
the effect of the 12 coils is $\frac{1}{5} \times 12 = \frac{12}{5}$ C.

And now both effects on the needle are in the same direction, hence the full effect is the sum of the two effects, or,

$$\frac{12}{5} + \frac{12}{5} = \frac{24}{5} \text{ C} = 4{\cdot}8 \text{ C}.$$

Fig. 4.

In this instrument (Fig. 4) the magnet is $\frac{3}{4}$in. long, and carries a pointer at right angles to it. When the poles of the magnet are parallel to the coil, then both ends of the pointer stand at zero on a graduated scale. Of course, there are two scales, one on each side of the instrument. One of the scales is marked off in true degrees, the other in numbers proportional to the tangent of those degrees, so that if two measurements give two deflections in degrees, the other end of the pointer will give approximately numbers proportional to the tangents of the degrees thus read. These numbers save much trouble, but it must be understood that for extreme accuracy it is best to refer to a table of tangents and obtain the values to more places of decimals. The scale numbers, once more, are approximate only.

The high-resistance coil is used in the measurement of small currents. Thus Kempe says: "In testing the strength of a current in milliamperes, the standard cell* is connected to A and B, and both plugs are removed from the plug-holes. There is then in circuit a total resistance of 1,070 ohms—viz., 750 + 320. As the E.M.F. of the cell is 1·07 volts, the resulting deflection of the galvanometer needle (which is adjusted by means of the adjusting magnet to 80 divisions on the outer scale) will be due to a current of

$$\frac{1{\cdot}07}{1{,}070} = {\cdot}001 \text{ ampere, or one milliampere,}$$

and any other deflection obtained with any particular current compared by direct proportion with the standard deflection will give the strength of that current in milliamperes.

"When the standard deflection is obtained the standard cell is removed, and the circuit from which the received current is to be measured is connected to terminal A, terminal B being put to earth."

Ballistic Galvanometers.—From what has been said it will be gathered that when a current is sent through the conductor ring, and continued constant, the galvanometer needle will be deflected, and come to rest in the deflected position. This is so. To increase the effect of a weak current field upon the needle, it is necessary to coil the conductor round the needle a number of times. In this, the ordinary form of galvanometer, the needle is made very light, but in cases where the duration of the current is brief, the reading of the galvanometer is taken, not from the position of permanent deflection, but by the "throw" or "swing" of the needle due to the magnetic impulse of the transitory current. A galvanometer used to measure the "throw" is called a ballistic galvanometer, and is made with a heavier needle, and so that the needle moves slowly to the point of furthest swing, which is thus easily read. Before the light needle of a galvanometer comes to rest, there is usually a considerable amount of oscillation around the point of rest. In using a ballistic galvanometer, the magnetic moment of the needle must be taken into account as well as the constant of the galvanometer.

Astatic Needles—Astatic Galvanometers.—It is very often convenient to have an instrument that need not compulsorily have its needle pointing magnetically north and south. To obtain this, it is necessary in some way to neutralise the earth's magnetic action upon the magnet. Prof. Cumming for this purpose used a magnetised

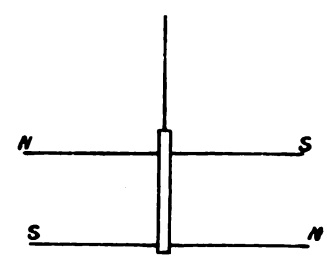

Fig. 5.

needle placed just below the movable needle. Nobili improved upon this by duplicating the needles, placing them one above the other, rigidly connected, parallel to each other, but with their poles in opposite directions, Fig. 5. It is almost impossible to have absolute astaticism, for this means two magnets of exactly equal strength with their poles in exactly the same vertical plane. If we could

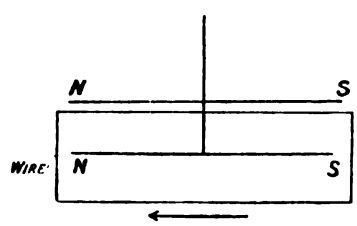

Fig. 6.

mechanically make such a system, then the earth's action on one needle would be exactly balanced by its action on the other needle, and the system would remain in whatever position it was placed without tendency to turn. It is

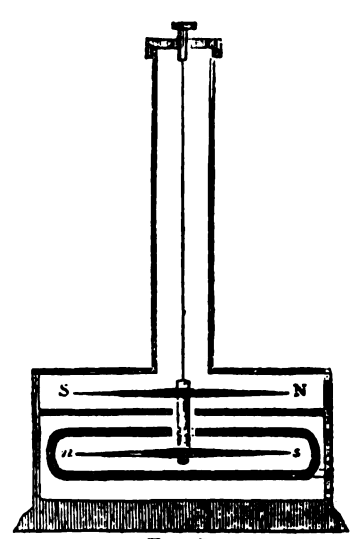

Fig. 7.

impossible to do this, so that instead of a perfect astatic system we usually get a system that acts as an exceedingly weak magnet, for if the needles are not exactly the same one can only set north and south by compelling the other

* This probably refers to a Daniell, not to a Clark cell.

Digitized by Google

to set south and north. If, therefore, one does overpower the other, the system is held in the magnetic meridian much less strongly than would one needle be by itself. Usually the more astatic the system is the greater the tendency to set east and west, the reason of this being that one needle tries to pull the other north and south, whilst the other wants to pull it south and north. The nearer to equality the more they agree to differ, and set half-way to each other's discing. A perfect astatic system should point anywhere with no tendency to alter the position in which it is placed.

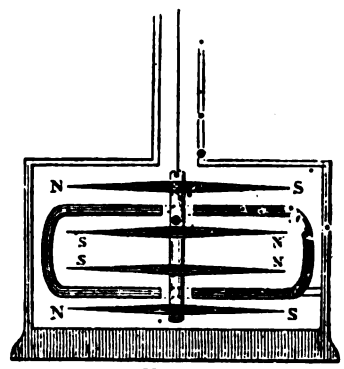

FIG. 8.

The principal use of the astatic needle is in the astatic galvanometer, in which the astatic system is deflected by a current through a coil similarly to the galvanometer needle previously mentioned. In the older instruments one of the needles is usually placed inside the coil, as shown in Figs. 6 and 7, the other outside. The current through

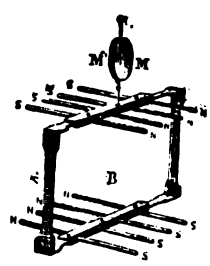

FIG. 9.

the coil will act so as to turn each needle of the astatic system in the same direction. Ampère's rule for the direction in which the needle will move has already been given. An extension of Nobili's galvanometer was proposed by M. Lebaillef, but it has been little used. He employed four needles, as shown in Fig. 8. Weber uses eight magnets, as shown in Fig. 9. The usual form of

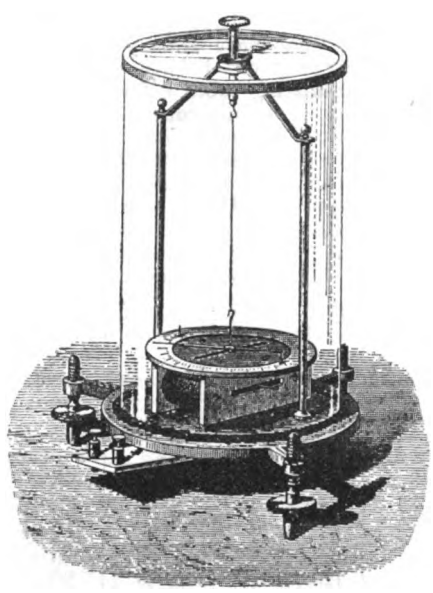

FIG. 10.

astatic galvanometer is shown in Fig. 10. The coil is wound upon an ivory frame, which also supports the circular scale, in the centre of which the upper needle is suspended. The ends of the coil are connected to binding screws, to which also the connections of the battery or other source of current can be made. The upper needle often carries a pointer, the more easily to read the scale correctly. The suspending fibre is fixed to a hook, which can be raised or lowered as required, so that when the instrument is not in use the system is lowered till the upper needle rests on the circular disc, and all strain is taken from the suspension. When using the instrument the astatic system is raised, and the levelling screws adjusted so that the needles swing quite freely.

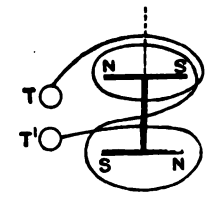

FIG. 11.

In the newer form of instruments, as we shall see, both needles are surrounded by the coils, as shown in Fig. 11.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is the balloting list for Council and officers for the year 1896 :

PRESIDENT.

Dr. John Hopkinson, M.A., F.R.S.

VICE-PRESIDENTS (*four to be elected*).

Sir David Salomons, Bart., M.A.
Sir Henry Mance, C.I.E., M.I.C.E.
Robert Kaye Gray, M.I.C.E.
Prof. S. P. Thompson, D.Sc., F.R.S.

ORDINARY MEMBERS OF COUNCIL (*12 to be elected*).

*Major A. H. Bagnold, R.E.
*Frank Bailey.
*G. von Chauvin.
*W. B Esson.
*S. Z De Ferranti.
*Prof. A. B W. Kennedy, LL.D., F R S , M I C E.
*William E. Langdon.
*Augustus Stroh
†Henry Edmunds.
†Prof J A Fleming, M.A., D.Sc., F.R S.
†Dane Sinclair
†J. W. Swan, F.R.S.

ASSOCIATE MEMBERS OF COUNCIL (*three to be elected*).

†Captain W. P. Brett, R.E.
†H. W. Miller.
†Sydney Morse.

HONORARY TREASURER.

Sir David Salomons, Bart., M.A. (Vice-President).

HONORARY AUDITORS.

Frederick C. Danvers, India Office, S.W.
Augustus Stroh

HONORARY SOLICITORS.

Messrs. Wilson, Bristows, and Carpmael, 1, Copthall-buildings, E C.

* Remaining on Council. † Recommended by Council.

THE ELECTRIC WIRING QUESTION.

BY FRED. BATHURST, ASSOCIATE.

(Concluded from page 621.)

With a tube complying with these requirements all possible electrical trouble is minimised, the insulation on the conductors themselves is protected from mechanical damage, and is enveloped in a preservative, rather than a destructive, element. Temperature changes are reduced to a minimum, and if the conduit resists acids, alkalies, and gases, the insulating material on the wire is so shielded that its life is indefinitely prolonged. It appears to me that the insulating tube does for "wiring" what the high-resistance incandescent lamp did for the "distribution" problem. I contend, therefore, that an insulating tube method of wiring will prove the ultimate solution of the "electric wiring question."

THE INTERIOR CONDUIT COMPANY'S SYSTEM.

Having now hit, as it were, every head within reach, by criticising to the best of my ability the existing systems, I am bound not only to apologise (as I do sincerely) to those whom my criticisms may have aggrieved, but endeavour to make some amends by setting up an idol of my own, which may give opportunity for retaliation. Accordingly, I have pleasure in showing

Digitized by Google

a few samples of the insulating tubes manufactured by the Interior Conduit Company, of New York, in the belief that they represent the highest achievement yet accomplished in the production of the ideal tube. This method of wiring originated with Mr. E. H. Johnson. This name, from its connection with the Edison companies, will be familiar to many. The system and process of manufacturing the tube and accessories have been worked out by Mr. Johnson in conjunction with Mr. Luther Steringer and Mr. E. T. Greenfield as co-patentees. The insulating material employed is a specially prepared hydrocarbon of the bitumen class. The necessary strength in tube form is obtained by using a peculiar grade of fireproof paper material which admits of impregnation. The system provides perfect immunity from fire, durability of insulation, accessibility to concealed wires, and reliable service. It has had extensive practical test in America, and more recently in Germany, where its reputation for being the safest, least expensive, and most practical method of wiring is now established. Perhaps the best confirmation I can give of this statement is the fact that we already count, in various countries, some two million incandescent lamps installed in the three varieties of tube—"plain," "brass-covered,' and "iron-armoured"—and have yet to learn of the first electrical fire arising from its use. Risking the criticism of "advertising," perhaps the best course that I can take is to examine this system in regard to the five cardinal points before mentioned of safety, durability, convenience, accessibility, and economy.

Safety.

We have noted that danger arises from deterioration of the insulating material on the conductors, and that this can be prevented by enclosing the wires in insulating tubes. These insulating tubes, or internally insulated metal tubes, have, therefore, an immediate advantage over plain metal tubes. Again, when deterioration does take place in a plain metal tube, the tube itself becomes a conductor, and invites deterioration at many points. If insulated tubes are used (with two conductors inside), the deterioration on one only brings additional stress upon the other conductor at one point. The tendency in this case is to create a "short-circuit" at the spot affected. In these particular tubes a short-circuit presents no danger, as the materials of which they are composed will resist the burning effect of the arc. Many tests have been made, and in every case it has been found that the "arc" increased in length until it broke, and severed the circuit without further danger. Any "short-circuit" trouble, then, removes itself, and its injurious effects are confined entirely within the tube. Since the presence of moisture is the principal cause of "short-circuit," the use of these tubes is likely to minimise the occurrence of trouble, because the tube material is non-conducting in respect to heat, and extraneous changes of temperature fail to produce internal condensation. The use of insulating tubes will also remove the increased danger in respect of wires employed for heating or power applications which may be temporarily overloaded, and in respect of wires protected by a fuse which through careless replacement has been made too large. It may also be that insulating tube methods of wiring will render it possible to materially modify our present practice in respect to "fusing."

While on this question of safety, I should say that there is only one point not yet entirely settled. It is whether the two insulated conductors should be kept together or separated—whether one or two tubes should be employed. Owing to the real necessity with a wood-casing system of keeping the wires apart, some authorities urge that this construction should be applied to tube methods, and that a separate tube should be used for each wire. In alternating-current circuits it is essential to keep the wires close together, to prevent a drop in voltage from inductional effects. Clearly, therefore, in this case both wires should by preference be in the same tube. Since in England two conductors are already allowed in "compo" pipes, I do not here anticipate objection being made to this construction in respect of an insulating tube which is electrically perfect and equal to "compo" mechanically. Moreover, in those positions where mechanical strength is imperative the insulating tube can be supplemented by an iron or steel covering. I maintain that theory points to the advisability of placing both wires together, and so far the results of practice favour this view.

Durability.

As far as present experience has gone, it shows that the bitumenised tube will under ordinary conditions last indefinitely. It can safely be embedded in the lime-and-sand plaster used in ordinary building construction. I may mention that the present tendency towards fireproof building construction is bringing into use certain cements caustic enough to attack nearly any material coming into contact with them. The problem thus presented has been successfully solved by the introduction of the "brass-covered" insulating tube. The bituminous material used in these insulating tubes is inert in its nature, and exercises no deleterious influence on the insulating material of the wires themselves. It has sufficient mechanical strength to resist any damage except that inflicted by gross carelessness or design, and in the case of chance mechanical injury to the tube the "accessibility" it provides renders repair easy. In respect of permanence and durability, the advantage of placing the conducting wires in channels which predetermine their relation to any contiguous conducting bodies is, I think, beyond question. The mischief done to wood casing and "compo" pipe by rats and other vermin is, in the case of these tubes, entirely obviated. From the fact that such inroads are successfully resisted, it would appear that bitumen disagrees with a rat's digestive machinery!

Convenience and Accessibility.

I have met some contractors who argue that a "conduit" method is not so convenient as "wood casing" or "rigid" methods. It is possible this has been their experience from a limited trial. I have no hesitation in stating that when wiremen become even slightly proficient in handling the material, they will prefer to instal "conduits." At least, this has been the universal judgment in other countries. "Boxes" and "elbows" do not present insuperable difficulties, nor do the "runs," when the rigid conduit can be made temporarily flexible by the use of heat. A perfect system of wiring should not only give a suitable channel for the wires, but must provide for the convenient jointing of the tubes themselves, and also for "switch" and "lamp" outlets. It should admit of the multiplication of small circuits from convenient "centres of distribution," as this construction avoids the necessity of joints in the wire, and permits equalisation of the voltage throughout the whole installation. An architect ought to be able to lay out the system and provide in his plans for the electrical installation as completely and intelligently as he now provides for steam or gas utilisation. The system I advocate satisfies these requirements, for, after the conduits have been erected and all danger from mechanical injury has passed, the wires can be readily drawn into their respective channels, and connected up to suitable distributing blocks. There are numbers of existing installations where over 1,000 lamps are in use, and in which any wire is "accessible" at any moment.

Economy.

An insulating tube system is also economical. With trained workmen, we estimate saving from 25 to 50 per cent. in the labour of installation. Even though the tube itself is comparatively expensive, if wires suitable to it are employed the total cost of material will compare favourably with any other system. The insulating properties of these tubes is such as to provide, approximately, an additional "300 megohms per mile" insulation resistance to the wire. We are beginning to appreciate the fact that, although we provide a costly "600-megohm wire," after having installed a few hundred feet our tests indicate a total insulation resistance of only a few thousand ohms. An insulating tube system can assist us to obtain a more commensurable result. If a high-insulation test has to be obtained in wiring work, practical experience shows there is little doubt that an insulating tube, and its suitably insulated wire inside, is commercially ahead of a relatively heavily-insulated wire. Perhaps the limit of economy will be reached when we know how to "earth" perfectly, and can use a bare copper conductor within a metal-covered insulating tube.

Conclusion.

I have already trespassed too long upon your patience, and would now only express the hope that those—I believe there are several present—who have already used insulating tubes will state their experience. I have ventured my personal opinion that the insulating tubes before you are the nearest approach yet existing toward the ideal method of wiring, and I trust that the verdict of those who have tried them will support this view. If this be so, I ask that this Institution, in considering "the question of electric wiring," will, in any rules it may issue, give recognition to, and make due provision for, the use of insulating tubes.

APPENDIX B.

Table Showing the "Insulation Test" Required in Various Countries. (Compiled from Rules of Supply Companies and Fire Offices).

Voltage of Circuits not to exceed 250 volts.

Size of installation, wired complete.	Country. England (London)	America. (New York).	Germany (Cologne).	Austria. (Vienna).
Amperes.	Ohms	Ohms.	Ohms.	Ohms.
10	500 000	2,000,000	100,000	50,000
25	250.000	1,800,000	40 000	20,000
50	125,000	400,000	20,000	10 000
100	—	150,000	10,000	5,000
200	—	80,000	—	—
250	25,000	—	4,000	2,000
400	—	40,000	—	—
500	12,500	—	2,000	1,000
800	—	11,000	—	—

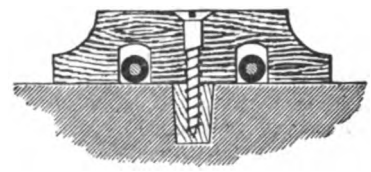
APPENDIX A.

DEVELOPMENT OF ELECTRIC WIRING.

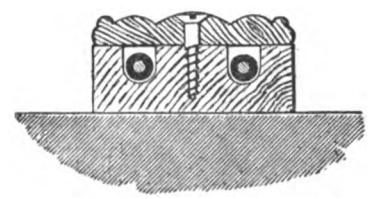
1. Wires secured on the surface by metal staples.

2. Wires directly embedded in plaster.

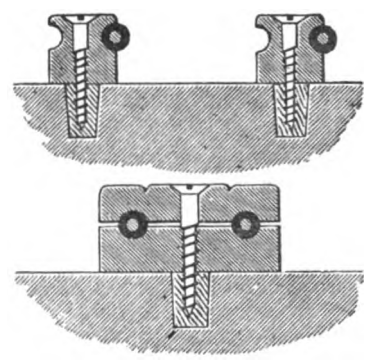
3. Wires secured on surface by wood cleats.



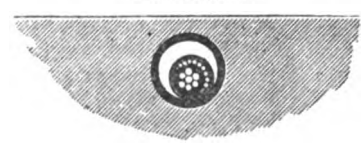
4. Wires secured on surface within wooden casings.



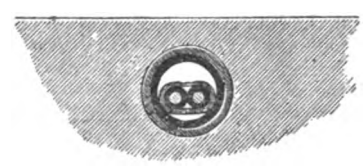
5. Wires secured on surface by means of porcelain knobs or cleats.



6. "Conduit" wiring beneath surface with twin (concentric) conductors.



7. "Armoured conduit" wiring beneath surface with twin (parallel) conductors.



APPENDIX C.

RESOLUTIONS ADOPTED AT THE MEETING OF THE UNDERWRITERS' INTERNATIONAL ELECTRIC ASSOCIATION, CHICAGO, AUGUST 17, 1893.

WHEREAS, under existing practices, but extremely few of the buildings in the United States which are wired are inspected before being closed in by lath and plaster; and

WHEREAS, an inspection after such closing in is incompetent and worthless, for the reason no means are known to the electrical profession by which the fire hazard of concealed or inaccessible circuits may be determined, and that a visual examination of all circuits must be had before immunity from fire hazard can be assured; and

WHEREAS, by the reason of non-inspection, the work of incompetent and irresponsible electricians remains for ever permanently concealed and uninspected, thereby affording ample opportunity for evading the requirements for safety, for practising gross impositions upon fire underwriters and the public, and imperilling millions in property valuations; and

WHEREAS, only through the use of insulating wireways is it possible to render concealed wiring permanently accessible; and

WHEREAS, such permanent accessibility renders it possible to thoroughly inspect at any time every installation so wired, and ensures trustworthy means for the detection of every piece of defective wiring of whatever nature; therefore, be it

Resolved, that the use of such insulating wireways for rendering concealed wiring permanently accessible be, and hereby is, most heartily endorsed and recommended; and be it further

Resolved, that such methods of accessible concealed construction be, and hereby are, advised for general use.

Resolved, that the secretary be requested to communicate with the American Institute of Architects, asking co-operation of their association in an endeavour to have architects when drawing plans for specifications make provisions for the channelling and pocketing of buildings for electric light or power wires.

Resolved, that they also be requested in specifications for electric gas lighting to require a two-wire circuit, whether the building is to be wired for electric lighting or not, and that no part of the gas fixtures or gas-piping be allowed to be used for the gas-lighting circuit.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D SC, F.R S.

LECTURE I.

(Continued from page 587.)

NON-ARCING METALS.

It has often been noticed that certain metals will hardly arc at all in a continuous way. If you take two solid cylinders of zinc or two cylinders of antimony and put them close together and connect them on to the electric light mains, and then start an arc by sparking across, the arc will not maintain itself. It splutters itself out instantly. This property has been made use of in America, where atmospheric disturbances are much more serious than in this country, for the purpose of constructing a non-arcing lightning arrester. Fig. 5 is a rough sketch of one form of this device. The inventor, Mr. A. J. Wurtz, made an exhaustive research to ascertain which of the metals do and which do not arc. He found that nearly all metals will arc,

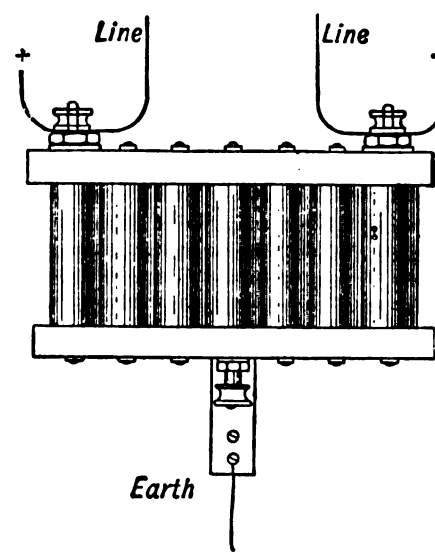


FIG. 5.

excepting zinc, antimony, and bismuth. Take the case of an electric station, working on an arc lighting system, supplying 40 or 50 lights in series. There is employed a potential of 2,000 or 3,000 volts. If a lightning flash were to start an arc from the outgoing line to the incoming line, it would set up a most destructive arc. In order to prevent any such catastrophe happening, there must be provided a lightning arrester. But the lightning arrester might go on carrying the arc if it were not made of non-arcing material. This is Wurtz's invention: a cylinder, made of a particular sort of brass, with a high percentage of zinc in it, is connected to one line, while another cylinder is connected to the other line. Between them—nearly touching one another—is a row of intermediate cylinders. The middle cylinder in the row is put to earth. Those on each side are not connected with anything at all, but merely fixed in a frame of stoneware or some non-conducting material. Then, if either of those lines is struck by lightning, there will be a momentary spark across those cylinders in series, and the discharge will go down to the earth instead of going to the power-house and deranging the machinery; but it will not persist as a continuous arc: the discharge will splutter itself out instantly. It is not precisely known why this effect occurs with the metals and alloys named and not with others.

TEMPERATURE OF THE ARC.

Until quite recently, the most wild guesses were all that could be learnt about the temperature of the arc, or of its various parts; such numbers as 10,000deg. C. and 500,000deg. F. were quite common. Becquerel, in 1860, suggested 2,070deg. C. to 2,100deg. C. as the probable temperature of the arc between carbons, his source of current being a battery of 80 Bunsen cells. In 1879 Rossetti published a research, based on observations of the radiation, in which he came, not without some doubts, to the conclusion that the respective temperatures

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

might be stated somewhat in the following terms: the temperature of the positive crater somewhere about 3,900deg. C., that of the negative peak about 3,1500deg. C. He concluded that the arc itself, although it gave, being gaseous, less light, was actually hotter, and he suggested 4,000deg. C. as being the best guess available. Rossetti's value of 3,900deg. C. for the temperature of the crater has been re-examined quite recently, in America by Nickolls, and in France by Violle. By two independent methods of measurements Violle arrived at numbers a little less, his final number at present being 3,500deg. C. He has arrived at this most recent measurement in a curiously direct way—viz., by a calorimetrical measurement. He arranged an arc in the following manner: The positive carbon was provided with a small end piece which at any moment could be knocked off and dropped into a calorimeter. This end piece was made the crater of the arc, and was allowed to burn away until it was quite thin; the supposition then being that it would nearly all be at the same temperature as its luminous surface. Then it was dropped off into the calorimeter, and the amount of heat it gave out in cooling was measured. The rather extravagant assumption had to be made, that the specific heat of carbon at this high temperature might be found by extrapolation from its known specific heat at lower temperatures; and the number arrived at agreed with the number derived from the observation of radiation. Mr. P. H. Gray has independently arrived at the value 3,400deg. So we may attribute a fairly reasonable accuracy to Violle's number, 3,500deg. We know that the lower carbon, the negative, is a good deal cooler. Violle's number for the negative carbon is about 2,700deg. C. He has recently brought forward evidence to show that the arc itself is probably hotter than either the positive or the negative carbon tip. That was previously a matter of inference from the nature of the radiations, spectro-photometrical observations being the basis. The new evidence is this: Make the arc using, not carbon, but a material which forms an arc at a lower temperature, zinc being the material in question. The temperature of the crater will, of course, correspond with the temperature of volatilisation of the zinc. Now, if into the flame between the positive and negative zinc tips you use some material which is less volatile or less fusible than zinc, you can again, by the aid of the spectroscope, satisfy yourself whether it is hotter or not. Violle found that the arc between the zinc poles could raise a piece of carbon to a temperature distinctly higher than that of either the positive or negative sides; consequently, by inference, the flame in the carbon arc is hotter than either of the two tips. It is to be hoped that other physicists will work at this question. There is really a great deal to be done on that part of the physics of the arc. Still more recently Violle has returned to the question whether the intrinsic brightness of the crater is independent of the strength of the current. His latest announcement is that when he took a very large piece of carbon, and made arcs with as small a current as 10 amperes, and as large a current as 1,000, the intrinsic brightness of the crater surface—that is to say, the amount of light emitted per square millimetre of surface—was the same.

Effect of Conductivity of Carbon Pencils.

If the pencils of carbon used are of insufficient cross-section or of a badly-conducting material, they will heat throughout their whole length, and waste an undue proportion of heat by offering a useless resistance to the current. From the point of view of economy a good-conducting quality of carbon is to be preferred. But, apart from the question of economy, the matter is of importance. If a pencil of insufficient section, in proportion to the current it must carry, is used as the positive carbon, the crater cannot be properly formed, and the arc will be more or less unstable, while the flame will lick around the rim. On the other hand, if the pencil is too thick relatively to the current, the crater will be very deep, and again the arc will burn unsteadily, as the crater shifts its place from moment to moment. For a 10-ampere lamp one frequently finds the positive pencil to be an uncored carbon 9mm. or 10mm. in diameter. If a carbon with a soft core is used, a slightly larger size is admissible. It is usual to employ for the lower negative pencil a carbon not cored, 1mm. or 2mm. less in diameter than the upper positive carbon.

If the carbon is of such poor conductivity, or so thin, relatively to the current it has to carry, as to become red-hot for more than a few millimetres beyond the luminous tip, it will waste by oxidation in the air, and become coned for a considerable length. A pair of such carbons are depicted in Fig. 6, at A. It was long ago suggested that the conductivity of carbons might be improved by plating them with a film of conducting metal. At B and C, in Fig. 6, are shown the forms assumed by carbons of the same quality, when they have been coppered or nickelled. The current flows freely down the external metal skin without materially heating the pencils along their length. In the immediate neighbourhood of the arc the metal is volatilised and disappears. Coppering is now seldom resorted to, as the carbon pencils of modern manufacture are of higher conductivity, and do not require to be coated. The conductivity of good moulded carbon pencils, such as are now used, is from 15 to 20 times as great as that of pencils sawn out of gas-retort carbon, being only from one-tenth to one-fifth ohm per foot of length. But coppering would reduce these values ten or twenty-fold.

Effect of Surrounding Gases on the Arc.

Another matter that has received extremely little attention is the effect on the arc of the surrounding medium. Until recently, it was not known what would be the effect of increasing the pressure of the air, or of surrounding the arc by different materials instead of atmospheric air. At a time before this 39 volts of back E.M.F. was as well recognised as it is now, it was supposed that this constant part of the voltage had something to do with the surrounding air; that, in fact, it was due to the oxygen and carbon combining. In order to disprove this notion, I had some experiments made three or four years ago with arcs burning in different materials, in chlorine, in coal-gas, in hydrogen, in nitrogen, etc. I found that it did not make one volt difference what the surrounding gas was. The 39 volts were still required as the minimum E.M.F. for a steady arc.

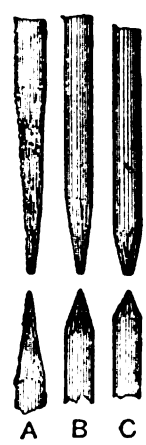

Fig. 6.

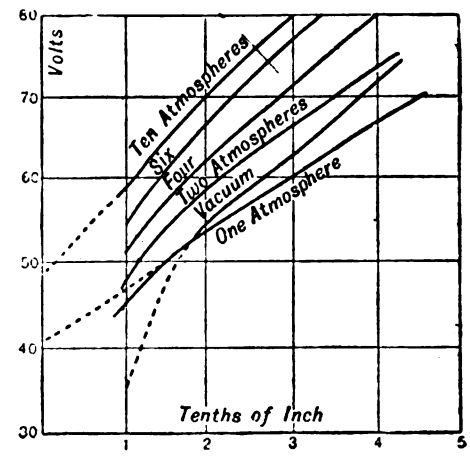

Fig. 7.

Incidentally I observed that the shape of the positive crater and of the negative peak is quite different, and differs in different gases. In coal-gas one finds that the hydrocarbon becomes deposited in the form of a mantle all round the crater, so that the negative peak penetrates up into a sort of chimney of deposited carbon. When one works at reduced pressures one begins to get into the vacuum-tube order of phenomena. The arc may be drawn out to a great length, and expands in size; but the luminosity of the tips of the carbons diminishes, and the phenomenon of the crater changes. Very little carbon is volatilised, and the E.M.F. required to sustain the discharge is lessened.

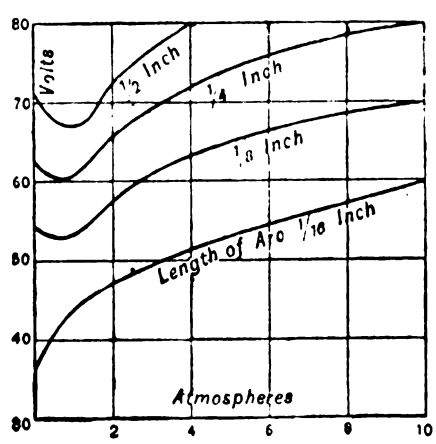

Fig. 8.

When, however, one increases the pressure, one meets with arc phenomena that are slightly different from those at atmospheric pressure. Here we have the justification of the view that the 39 volts is due to the work done in the vaporising of the carbon. So far as I know, much the most complete experiments yet made on this point are those made in America by Dr. Louis Duncan and some of his students. Figs. 7 and 8 embody in diagrammatic form the principal results of the researches.

Duncan caused the arc to be made in a vessel into which the air could be pumped, or from which it could be exhausted. Take, first, the case of the arc made at the ordinary pressure of one atmosphere. The sloping line marked "one atmosphere," in Fig. 7, here shows the connection between the volts and the length of the arc; the lengths in successive experiments being plotted out horizontally in one-tenths of an inch.

NEW PARLIAMENTARY BILLS.

The Dover Corporation are applying in the ensuing session of Parliament for a provisional order authorising the construction of tramways in the borough, to be worked by animal, electrical, or other power. Bristol Tramways and Carriage Company, Limited, seek to obtain a provisional order to authorise the construction of tramways in the city and county of Bristol and urban district of Kingswood (Gloucestershire) and the use of electrical power upon the company's tramways. A provisional order is sought to authorise the incorporation of a company to construct street tramways in the Potteries district, to be worked by electrical power applied on the overhead system or otherwise. The Plymouth Corporation are seeking powers to construct additional tramways in the borough, and to work them by animal, electrical, or other power. Longton Corporation are applying for powers to construct tramways in the borough, to be worked by animal, electrical, or other power. The Great Western Electric Light and Power Company, Limited, intend to apply for a provisional order to authorise the supply of electricity for public and private purposes within the districts of St. George, Kingswood, Stapleton, and Warmley, and to enable the company to construct all necessary works, etc. King's Lynn Corporation seek power to construct works, lay mains, etc., for the production and supply of electricity within the borough. The Manchester Corporation are seeking powers to extend their area of electricity supply. The Keswick Electric Light Company, Limited, are applying for additional powers with regard to the supply of electricity within the township of Keswick and certain portions of the townships of St. John's, Castlerigg, Wythburn, Underskiddaw, and Above Derwent. The Altrincham Electric Supply, Limited, seek to obtain a provisional order to authorise the construction and equipment of works, laying of mains, etc., for the purpose of supplying electricity within the district of Ashton-on-Mersey and part of Bucklow.

THE EDISWAN FIREMEN'S DINNER.

The fourth annual dinner of the Ediswan Volunteer Fire Brigade took place at the Holborn Restaurant on Saturday last. Though nominally a firemen's dinner, it was practically a dinner of the firm, all departments of the works being represented. Major S. Flood Page presided, and there were also present Mr. H. C. Gover, Mr. C. M. Downie, Mr. C. F. Proctor, Mr. A. W. Torkington, Mr. Musgrave Heaphy, Mr. T. O. Belshaw, Mr. C. Undrell, Mr. W. Wake, Mr. A. W. Hill (captain of the brigade), Mr. F. Thompson (secretary), Mr. Millar and Mr. Dale (captains of neighbouring brigades), Mr. Hill, Mr. Woodley, Mr. Johnson, etc.—the total number present being about 80.

Mr. Gover, secretary of the company, in proposing "The Health of the Edison and Swan Company," congratulated the chairman on his recovery from his recent ill-health. Mr. Gover claimed that had it not been for the Ediswan Company and the action of their Board, the position of electric lighting in England would have been very different to what it was at present. Much of it, indeed, would have had no existence or would have been indefinitely postponed.

Major Flood Page, in replying, said that the names of Edison and Swan were known throughout the whole world, and there were not many places in the world where the Edison and Swan lamp was not also known. With reference to the position of the firm in regard to their competitors, he confessed that the incandescent gas light had certainly produced marvellous results. It was now 15 years since he was shown the incandescent light in Paris and sold gas shares in consequence. The same gentleman that showed him the incandescent lamp had just shown him also in Paris the Denayrouse lamp. They would see that light in England before long, and it put the arc lamp into the shade. It was a 5,000-c.p. lamp. However, whatever competition they might have to face the incandescent electric light would remain the light for domestic use, since it was beyond question the best for that purpose. The policy of the company was always to turn out the highest class work, and in regard to price it must be remembered that the cheapest was not the best. It was an open secret that fresh patents had been taken out by Mr. Swan. The company were selling more lamps now than during the protected period, and they would hold their own. In proposing "The Visitors," the Chairman referred to the high-voltage question, and said that so far as high voltage was concerned the lamp was the least part of the difficulty. It was simply a matter of study, and he hoped Mr. Woodley and their friends of the lamp department would be able to meet whatever reasonable demands were made. He would, however, like to know the views of fire insurance companies on the question. He doubted whether many installations ought to be subjected to the higher pressure without being properly inspected.

Mr. Musgrave Heaphy, who replied, said that the high-voltage question was being seriously considered, and he would not speak on it at present. He complimented the brigade on the smart turn out he had witnessed at Ponders End.

During the evening an exhibition of the kinetophone and various American fire-alarm apparatus was given by Mr. Johnson.

NEW CEILING-ROSES.

Our illustrations depict two new forms of ceiling-rose as made by Messrs. Baxendale and Co., of Miller-street, Manchester. One of the two main improvements is shown in Fig. 1 and the other in Fig. 2. The first consists in providing the rose with two "legs," or "feet," so that it may be placed straddlewise

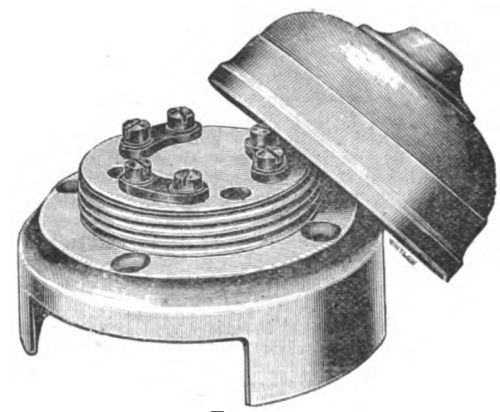

Fig. 1.

across the casing. There is thus no necessity to cut away anything except the casing cover, and no need for wood pattrasses or blocks. The rose is provided with four hold-down screw-holes, two in the centre line of the casing, and the others, one through each "leg," on each side of the casing. Obviously, ceiling-roses of this pattern can be much more quickly, neatly, and strongly fixed in position than the ordinary. The gap in the base is made to suit various thicknesses and sizes of casing, and they are provided with stop-ends, or non-throughway gaps, to give a finished appearance to ends of casing.

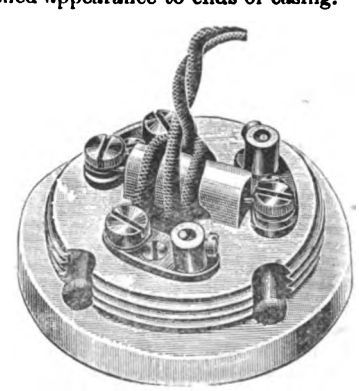

Fig. 2.

The second improvement consists (Fig. 2) in a combined fuse-shield and cord-grip. The base is formed with an arch-piece of porcelain. This arch-piece is pierced longitudinally, and through this is threaded the fuse, while the flexible cord may be twisted round it and all strain taken off the terminals. The arch-piece, or porcelain tube, affords a mechanical protection for the fuse, and, in the event of the fuse "going," prevents the metal from getting on to the cord. These "Beanco" ceiling-roses are made in various sizes, and with either or both of the improvements combined.

LEGAL INTELLIGENCE.

GASKELL AND ANOTHER v. GOSLING AND ANOTHER.

This case came before the Lord Chief Justice, without a jury, in the Queen's Bench Division. It was an action brought by the plaintiffs, a firm of manufacturers of electrical apparatus, carrying

Digitized by Google

on business in Longport, in the Potteries, to recover £488. 9s. 3d, balance of account for goods sold and delivered to a person named Kelly, who was receiver for the debenture-holders in a London company, named Poole and White, who dealt in electrical apparatus. The defendants denied liability. Mr. H. Reed, Q.C. and Mr. Ansell were counsel for plaintiffs; Mr. Jelf, Q.C., and Mr. Hamilton for defendants.

Mr. Reed said that though the action appeared on the face of it as one simply for goods sold and delivered, yet it actually raised as important a question to the commercial public as could well be conceived—namely, whether trustees for debenture-holders who had appointed a receiver to carry on the business of a company which was in liquidation were themselves liable to pay for goods supplied to the receiver to enable him to carry on the business. The defendants were members of a London firm of bankers—Messrs Gosling and Sharpe—who were holders of some £3 000 worth of second debentures issued by the firm of Poole and White which had gone into liquidation. One often heard, said counsel of cases where persons supplied goods to companies, and, on applying for payment, were met by the debenture-holders' claims; but here there was something of a converse case for goods supplied to a receiver acting for debenture holders, and when payment was applied for the plaintiff was told that the goods were supplied to the company, and he must apply to the company for payment, it being well known that the company at the time was in liquidation and had no means of paying its debts. It appeared that in July, 1892, it being reported that the debenture-holders' securities were in danger, the defendants, as trustees for the debenture-holders, took possession of the property of White and Co., and appointed a receiver named Kelly, who conducted the business for the benefit of the debenture holders. Subsequently the company went into liquidation, but the liquidator could not touch the debenture-holders' property, and Kelly continued to carry on the business The plaintiffs supplied Kelly with £700 worth of goods, which sum was reduced by creditors to the amount now claimed; and counsel submitted that the debenture-holders were bound to pay for these goods which Kelly ordered for the purpose of enabling him to complete electrical apparatus in stock, so that he might dispose of the apparatus for the benefit of the debenture-holders.

The **Lord Chief Justice** said it was in his opinion a question of fact, though to be determined by considerations of law. He had to ask himself who were Kelly's principals. It was clear that after the winding-up order the company, *qud* company, ceased to have any actual existence, and it could not be doubted that the defendants were the real parties carrying on the business. He had to determine simply whether the plaintiffs had made out satisfactorily to his judgment that this was a case in which from December 25, 1893, to January 31, 1895 the present defendants were, in fact, undisclosed principals. He thought they had, and, accordingly, judgment must be for the full amount claimed, with costs. Execution was stayed pending an appeal.

JEFFRIES v. THE BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

This was an action in the Queen's Bench Division, before Mr Justice Hawkins and a common jury, for damages for personal injuries caused by the alleged negligence of the defendant company.

There appeared for the plaintiff Mr. Kemp, Q.C., and Mr. Cagney; and for the defendants, Mr Tindal Atkinson.

The **Plaintiff** (Mr. George Fish Jeffries) said that he was 73 years of age. He sold tea, champagne, and reversions, earning £2 or £3 a week. On January 8, 1895, he was in the City road, near the Artillery-ground, about seven in the evening. He tripped against a board covering a hole in the pavement, in which the defendant company were laying wires. He fell and became insensible. His eye and head were much damaged, and he had since been attended for his injuries. Next day he went to look at the place, and the boards had been bevelled off at the edges. He had since suffered much with his eyes, and from nose bleeding and giddiness He could no longer walk much, and had been unable to attend to his business. Up to the time of the accident he could walk 25 miles a day.

In cross-examination he said: Very likely he bought 20lb. of tea the week before the accident. He did not buy on commission but bought and retailed it. Perhaps it was 40lb. or 50lb He blended teas, 10 or 12 tons in the year, and made a profit of 6d. a pound. He had no list of customers, and he kept no books.

Witness, continuing, said that he tried to get a bed at several places after the accident, as he could not go home, but they would not take him in, as they thought he was a fighting-man, and he had to sleep in a common lodging-house. He did not tell a servant of the company just after the occurrence that he would give him a bottle of champagne if the company paid him 30s. compensation. Before the accident he carried glasses, but only as an ornament. They were a great set-off to a man, but afterwards he needed them for use, and very strong ones.

The jury ultimately awarded the plaintiff £50 damages.

CHELSEA ELECTRIC SUPPLY COMPANY.

In the actions of Sanden and Fowler against the above company counsel moved for a sequestration order for disobedience or breach of an injunction granted in respect of vibration caused by the defendants' machinery. After some discussion the motions were directed to stand over until to-day (Friday) in order that witnesses might be cross-examined in court.

HERCULITE AND ELECTRICAL MANUFACTURING COMPANY.

The *Financial Times* says that, on the petition of the Harburg and Vienna Indiarubber Company, a supervision order has been made in the voluntary winding up of the Herculite and Electrical Manufacturing Company, Limited.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Cleator Moor.—Tenders are invited for an electric light installation in the central stores of the Cleator Moor Co-operative Society. Particulars will be found in our advertisement columns.

Betanzos.—Tenders are invited by December 28 for the concession of the electric lighting for 25 years of the town of Betanzos, Spain. Conditions of La Direccion General de las Administraciones Locales, Madrid.

Ploesti.—The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town. Conditions from La Mairie de Ploesti Roumania.

Saarbruck.—The Railway Telegraphs Inspection invite tenders by December 16 for the supply of 28 standard Morse apparatus. Conditions for one mark from Die Eisenbahn-Telegrapheninspection, Saarbrücken, Germany.

Manchester.—The Markets Committee desire tenders for the supply and erection of accumulators, columns, lamps, and wiring for the lighting of the Foreign Animals Wharf, Mode Wheel. Particulars will be found in our advertisement columns.

London, S.W.—The Secretary of State for India is prepared to receive tenders for caissons, air-compressing and electric light plant. Particulars are to be obtained from the Director-General of Stores, at the India Office, S.W., and tenders must be delivered by December 10.

Aussig.—The communal authorities propose to have built a seven-mile single-line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Leyton.—The Leyton Urban District Council invite tenders for electric lighting works as follows: Contract No. 1, central-station buildings; (3) gas-engines, travelling cranes, piping, etc.; (4) dynamos, switchboards etc.; (5) storage batteries; (6) five miles of mains, including laying Particulars will be found in our advertisement columns

Belfast.—Messrs. P. and F M'Glade invite tenders for supplying and fixing an electric plant for lighting their new premises, The International, corner of York-street and Donegall-street. Copies of specifications can be had, and plans inspected, on application to Messrs. George Coombe and Co., consulting engineers, Castle-lane-place, Belfast.

Charkow.—The Mayor of Charkow is prepared to receive tenders for the supply of steam and electrical engines for lighting, as well as apparatus and essential parts necessary for an installation of electric lighting of 6 000 incandescent lamps and 500 arc lamps. Illustrated catalogues and price lists, with lowest quotations, to be sent to the Mayor of Charkow, Russia.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.—The Administration des Télégraphes require tenders by December 18 for the supply of various large lots of pine telegraph poles. Special cahier des charges No. 26 at the Brussels Bourse.

Transvaal.—The General Consul of the South African Republic asks tenders for the delivery of 5 000 k.g. 2 mm hard-drawn copper wire for the Government telegraphs Tenders which are not in American Hotel, Leidsche Plein at Amsterdam, before the 20th December, 1895 will not be taken into consideration. The conditions for the delivery can be furnished on demand by Brothers Belinfante, Paveljoensgracht, The Hague, at the price of 1s.

Leicester.—The Corporation invite tenders for the supply and delivery of the necessary cast-iron pipes and connections, from 2in. to 24in. in diameter, required during 12 months ending December 31, 1896 for the Gas and Electric Lighting Committee. Specification and form of tender to be obtained from Mr. Alfred Colson, M.I.C.E., engineer and manager, Millstone lane, Leicester. Tenders, addressed to Alderman Lennard, chairman and endorsed "Tender for Cast-Iron Pipes, etc.," are to be delivered by 11 a.m. on December 7.

London, N.—The Great Northern Railway Company invite tenders for the supply of new and the purchase of old stores for 12 months from January 1. A list of the contracts and separate forms of tender for each contract may be obtained upon application to Mr. Martin, the stores superintendent, Doncaster, by whom every information will be furnished, and the patterns of telegraph and electric lighting material will be exhibited at the telegraph stores, Retford. Tenders, addressed to the Stores Committee, marked on the outside with a description of the stores tendered for, must be sent to the company's offices, King's Cross, in the envelopes specially provided, so as to be received by 10 a.m. on December 7. Mr. William Latta, secretary, King's Cross Station, London, N.

Digitized by Google

Durban (Natal).—The Corporation desire tenders for the supply, for delivery at Durban, and fixing at Durban, of steam and electrical plant for the lighting of the borough by electricity. The work will be executed under the direction of Mr. Fletcher (borough engineer) and Mr. Hadfield (electrical engineer) at Durban. The plant required includes high-speed engines, dynamos, cables, arc and other lamps, accumulators, etc. Specifications and plans can be obtained from Mr. W. H. Radford, C.E., Angel-row, Nottingham, consulting engineer to the Corporation, on deposit of £5. 5s., which will be returned on receipt of a bona fide tender. Sealed and endorsed tenders, in duplicate, must be delivered at the offices of Messrs. Webster, Steel, and Co., agents to the Durban Corporation, 5, East India-avenue, Leadenhall-street, London, E.C., by 28th inst.

RESULTS OF TENDERS.

Cordova.—The contract for the electric lighting of the town of Cordova, Spain, has been awarded to Señor Francisco Caballero, who quoted 78 pesetas per 10-c p. lamp per annum.

Tunbridge Wells.—Mr. F. Bruce, of Castle-road, Hastings, has secured the contract for installing the electric light throughout Messrs. Metcalf and Kirkpatrick's establishment in Wellington-place and also at the Kentish Hotel, Tunbridge Wells.

Brussels.—For supply to the Municipality of Brussels of pipes and apparatus for electrical distribution: MM. Denis, à Forest, 10·80fr. per 100 kilometres; Forges de Clabecq, 10 98, 10·98, 10·98, 12·48, 12·48, 12·48, 14·48, 14·48, 14·48, and 14·48 francs, in the order of the cahier des charges.

Eccles (Manchester).—The Town Council are recommended to accept the tender of the Manchester Edison-Swan Company, Limited, for the carrying out of the works of electric lighting according to specifications at the sum of £13,792, and subject to the Local Government Board granting to the Council borrowing power adequate for the execution of the whole scheme of electric lighting.

Clacton-on-Sea.—The following were the tenders for a complete installation of electric light at the convalescent home, for the Weekly Board of the Middlesex Hospital. Mr. Adrian Collins, A.M.I.C.E., 61, Old Broad-street, E.C., was the consulting engineer:

	Generating plant.	Wiring.
Siemens Bros., Limited	£3,153 0 0	£850 0 0
Mather and Platt	3.164 15 0	568 0 0
Johnson and Phillips	2,333 19 0	1,246 19 0
Crompton and Co., Limited (accepted)	2,370 17 0	697 0 0

Paris.—The adjudication for the supply to the municipal authorities of Paris of two 35 kilowatt dynamos capable of working at 110 or 160 volts has resulted as follows:

	Price.	Guaranteed efficiency, per cent.
Sautter, Harlé et Cie	12.500fr.	90
Maison Breguet	12,280fr.	87
Société Alsacienne	11,800fr.	90
Etablissements Cail	11,500fr.	90
L'Eclairage Electrique	9,500fr.	90
Compagnie Electro-mécanique	8 600fr.	91 at 110V. 89 at 160V.
Compagnie de Fives-Lille	7 685fr.	90
Société Gramme	7,390fr.	93
Postel-Vinay (accepted)	6,600fr.	90

BUSINESS NOTES.

Stafford.—The Town Council have decided to put up two arc lamps in the Market-square.

Eastern Telegraph Company.—The receipts for the month of November were £69,461, against £64,095 for the corresponding period of 1894.

Direct Spanish Telegraph Company.—For the month of November the receipts were £2,414, against £1,738 for the corresponding period of 1894.

Die Aktiengesellschaft fur elektrische Unternehmungen in Berlin (Union) has resolved to increase its capital from 15,000,000 marks to 30 000,000 marks.

Eastern Extension Telegraph Company.—For the month of November the receipts show an increase of £7,361 as compared with the corresponding period of 1894.

Bury St. Edmunds.—The Electric Lighting Committee have decided to entrust Mr. Medhurst with the preparation of a report on the electric lighting of Bury St. Edmunds.

Walthamstow.—The District Council have received letters from four firms with reference to a scheme for lighting the district by electricity, and have referred them to a committee.

Stockton.—The Stockton Town Council have agreed to appoint a committee to confer and visit other towns with respect to the provision of an electric lighting installation for the borough

Commercial Cable Company.—A quarterly dividend of 1¾ per cent., payable on January 2, has been declared. The transfer books will be closed on December 20 and reopened on January 3

Paper-Mill Lighting.—Messrs. Roger Dawson, Limited, of 53, Berners-street, London, W., have received instructions to instal nearly 500 lights at the London Paper Mills, Dartford, with plant.

Barnsley.—The Town Council have decided to fix the price of electric energy for motors at 3d. per unit.

Manchester.—The special meeting of the Town Council has been held to authorise the applications for a provisional order to extend the area of electrical supply and also for tramway extension.

Blackpool.—The Town Council have adopted a recommendation from a departmental committee to instruct the electrical engineer to prepare a scheme for the extension of the electric light works.

Bath.—The City Council have passed a recommendation of the Lighting Committee that the electricity company be asked to extend the hours of lighting half an hour each morning for three months.

The Telephone in East Anglia.—The National Telephone Company have notified their subscribers in Norwich, Ipswich, and Great Yarmouth of a reduced scale of rates for local communication in those towns.

Hamburgische Elektrizitatswerke.—This Company proposes to increase its capital by 6,000,000 marks and to acquire from the Elektrizitäts-Gesellschaft Schuckert the electricity works in the town of Altona.

Chelmsford.—In connection with the Arc Works fire, the subscription list started on behalf of the men temporarily thrown out of employment has been headed by 100 guineas from Messrs. Crompton and Co.

Royal Electric Company of Montreal.—Application has been made to the Stock Exchange Committee to allow the further issue of £34 000 sterling 4½ per cent. first mortgage debentures to be quoted in the official list.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended December 1 amounted to £1,020, as compared with £902 in the corresponding week of last year, being an increase of £118

Electric Lighting of Railway Carriages.—The Furness Railway Company have decided that, as an experiment, two of their passenger trains shall be fitted with Messrs. J. Stone and Co.'s system of electric lighting

Western Union Telegraph Company.—In its past financial year, the Western Union—one of the greatest of the American telegraph companies—added 11,859 miles to its wire lines, and 10 000 miles of that length added were of copper.

City of London Electric Lighting Company, Limited.—With reference to the issue of £100,000 5 per cent. debenture stock, applications for £522,335 debenture stock have been received, and letters of allotment and of regret have been posted.

Merthyr Tydfil.—A correspondent writes: "There is a possibility that Merthyr will in due season become as advanced as Abercanaid in the matter of electric lighting, notices having been given of an intended application to the Board of Trade for a provisional order."

Uddingston (Lanark).—"The gas in the village of Uddingston again gave out before seven o'clock on Tuesday night The evening schools, which are largely attended, had to be closed." So says the *Scotsman*. No wonder the residents are talking of introducing the electric light.

Waterloo (Liverpool).—The District Council have received a letter from the Liverpool District Lighting Company giving notice that they intended to apply for a provisional order to light Waterloo and Crosby with electricity. A committee was appointed to oppose the application.

Electrolytic Research Syndicate, Limited.—This Company has been registered with a capital of £1,000 in £1 shares. Object: to acquire any patents or inventions relating to the production of chrome and other metals by electrolysis or other kindred methods and to develop and work the same.

Allgemeine Elektrizitats-Gesellschaft.—We gave an abstract of the annual report of this Company in our issue of November 22, p. 601. We should add that the Electrical Company, Limited, of 122 and 124, Charing Cross-road, London, W.C., are the sole representatives for Great Britain and the Colonies of the German firm.

City and South London Railway.—The returns for the week ended December 1 were £987, compared with £928 for the corresponding period of 1894, being an increase of £59. The total receipts for the half-year 1895 were £19,549, compared with £19,576 for the corresponding period of 1894, being a decrease of £27.

Peterborough.—The engineer has produced before the City Council plans and descriptions of the proposed scheme of electric lighting and explained them He was instructed to prepare an estimate making provision for street lighting by electricity, and showing what would be the difference between the cost of electricity and gas.

Appointments Vacant.—The Vestry of St. Mary, Islington, require three electricians, one switch-room attendant, four engine drivers, four stokers, one foreman fitter, one timekeeper and storekeeper, two arc lamp trimmers, and one messenger in connection with the electric lighting station. Further particulars will be found in our advertisement columns.

Neston (Cheshire).—The electric light question continues to be the prevailing topic of conversation in the district, and the feeling in favour of adopting a well matured scheme appears to be growing as the various problems are threshed out. Some of the more important residents in the neighbouring districts have approached the promoters with a view to taking current from the proposed works if practicable.

Digitized by Google

Sale of Electrical Apparatus.—The London Salvage Association, acting for the Thames Conservancy, intend to sell on December 9, at the London Commercial Salerooms, Mincing-lane, E.C., two Willans high-speed engines and a quantity of electric light fittings and stores, ex s.s. "Durham." Messrs. R Lyon and Co. are the auctioneers. Particulars will be found in our advertisement columns.

Dover.—At the last Town Council meeting it was remarked that several gas lamps, including the light in the Market square, were blown out by the gale which had disarranged the electric lighting. A letter from the electric light company, asking that the terms "dusk" and "dawn" should be substituted for "sunset" and "sunrise" in the agreement, was referred to the Lighting Committee for consideration.

Mevagissey Electric Lighting Company, Limited.—This Company has been registered with a capital of £1,500 in £1 shares. Object: to enter into an agreement with Veale and Co., Limited, for the establishment of an electrical installation (and the necessary machinery) in the town of Mevagissey, Cornwall, and to carry on the business of electrical engineers and suppliers of electricity (for all purposes) in all its branches

Birmingham.—Commercial prospects in Birmingham and South Staffordshire district are exceptionally bright. Enormous orders for axles and wheels, it is stated, as well as 10,000 iron telegraph poles, have been placed for the new Uganda railway, and a contract for £9,000 worth of iron and steel work has been signed with the Midland Railway. One Birmingham cycle firm, it is added, has advertised for no fewer than 1,200 extra hands.

Torquay.—Mr. F. J. Crocker has proposed that the Town Council should consider the question of acquiring and working the property of the Torquay Market Company, pointing out that the market buildings would be an admirable site for a central electric lighting station, and that the slaughter-house site at Upton would serve for the location of the proposed refuse destructor. The matter was referred to a committee of the whole Council.

Bangor (N.W.).—The *Observer and Express* of November 29 says that at Bangor the air is strongly charged with electricity, and the question of the suppression of gas by the electric light continues the main topic of discussion in the university city. "The resolution passed at the hastily-summoned meeting of ratepayers, held at the Penrhyn Hall on Friday night, was tantamount to a vote of censure upon the Town Council; but whether they regard it as such remains to be seen."

Bangor (Antrim)—With regard to the scheme for the improved lighting, it is now generally believed that the greater number of the ratepayers of the town are opposed to the large extension of the gasworks contemplated by the Commissioners, at a cost of between £5,000 and £6,000, in view of the recent improvements in electric lighting. It is believed that the electric lighting scheme now under the consideration of the Board will to a large extent take the place of the proposed gas extension.

Halifax.—An electric installation of 300 incandescent lights has been erected at Stones Mill by Mr. C. F. Fox, electric engineer, Halifax. Mr. Fox has also been entrusted with the electric lighting of Messrs. J. Crabtree and Sons' cotton mill, Salterhebble. The Trades and Labour Council are going to send a deputation to the Town Council asking them not to permit a private company to lay down a system of electric trams. If tramways were laid, it should be by the Town Council and under their control.

Buxton.—The Chairman of the Urban District Council said at the last meeting that they had received a letter from the Board of Trade in reference to the draft *re* the Electric Lighting Act. He did not know whether they had advanced enough to discuss that question. If left in the hands of the Electric Lighting Committee they could give the Council the cream of it in their report. This was agreed to, Councillor Cooper remarking that he was going to call a meeting of the committee early next week.

Dundee.—The Gas Committee of the Dundee Town Council have received an application for a supply of electric energy from a firm in Tindal's-wynd The application was granted, and the committee authorised the necessary agreement to be entered into. It was reported to the Gas Committee that coal was being supplied at the electrical station to the extent of about 40 tons a week without contract. The clerk was instructed to advertise for tenders for a supply of coal for the station until April 30.

Cork.—The minutes of the Electric Lighting Committee of the Corporation show that the town clerk was authorised to obtain additional expert advice as to the probable cost of lighting the city by electricity. The town clerk explained that he had arranged with the engineer of the electric light works in Dublin to furnish an estimate at the cost of 10 guineas. This had been done in order to fortify the Corporation in applying for a provisional order, as the estimate of Mr. Smith had been questioned in certain quarters.

Brierley Hill (Staffs.).—The Lighting Committee of the Urban Council have recommended that electrical engineers be engaged, at a fee of 30 guineas, to advise the Council as to the adoption of the electric light. Some members urged that the gas company should be approached as to a reduction of price and increase of illuminating power before any information was obtained as to the electric light. Ultimately the subject was adjourned for a month, and the report referred back to the Lighting Committee.

Shrewsbury.—A local paper says: "Our enterprising tradesman, Mr. L. Scholz, hairdresser, Pride-hill, has recently added another novelty to his establishment; besides having his premises illuminated by the electric light, he has had an apparatus fitted up by which the shafting from which the brushes are propelled is driven by electricity Anyone who has been operated upon under the new system cannot but recognise its superiority over the old hand power. The apparatus has been fitted up by Messrs. Lea and Son, electricians, of this town."

Edinburgh—The dome of the proposed new observatory on Calton Hill will be worked by an electric motor. The Town Council have decided to set up a new standing committee for the electric lighting, and it was remitted to the committee to consider and report as to what extensions should be made to the machinery and mains in view of the probable demand for next winter. Mr. Mackenzie explained that they had now wired on to their system 43,000 8 c.p. lamps, in addition to the street lamps. That, in seven months, was more than Prof. Kennedy expected them to have in three years.

Coventry.—The newly constructed electric tramways have been officially inspected on behalf of the Board of Trade by Major Cardew, who was accompanied by the Mayor (Alderman Loudon), Alderman Marriott (chairman of the General Works Committee), Alderman Worwood (vice-chairman General Works Committee), Councillor West, Mr Lewis Beard (town clerk), and Mr. E. J. Purnell (city surveyor), the tramways company being represented by Baron Turquoin and Mr. W. Sebastian Graff-Baker, directors. The system is the overhead conductor system, and the trial trips have proved very successful.

East Grinstead — The General Purposes Committee have reported to the Urban District Council that, having met Messrs. Lucas and Pike, electrical engineers, they cannot advise the Council themselves to undertake the installation of electric lighting, but recommend the Council to give an undertaking for 10 years to use electricity for street-lighting, providing the proposed company will undertake to supply arc lamps of 2,000 c.p, at a cost not exceeding that now paid for three ordinary street lamps, burning no less than the same number of hours, the whole arrangements to be subject to an agreement approved by the Council.

Copper.—The *Financial News* says that although the stocks of copper in England and France and afloat thereto are 4,652 tons smaller than they were at the end of October, the price of Chili bars on November 30 was exactly £2 lower than on October 31. The total supplies last month only came to 9,145 tons, while the deliveries amounted to 13,797 tons, and as consumption in the United States has more than kept pace with the increase in production, it is strange, the journal adds, that the fall in price should have taken place. At present the visible supply only amounts to 45,731 tons—figures which have had no parallel for the last seven years.

Gravesend.—The Town Council have received a letter from Messrs. L V. Riley and Co., stating that it was proposed to apply for a provisional order, and, if granted, they would be prepared to guarantee to supply electricity in Gravesend at a charge not exceeding 6d. per unit; to complete an installation equal to a supply of not less than 2 000 16-c p. incandescent lights within a year of the date of the order, and to enter into an agreement giving the Corporation the option of purchasing the installation at the end of seven years and within 14 years at a price equal to 10 per cent. advance on the capital outlay. The letter was referred to the Finance and Works Committees conjointly.

Aston (Birmingham).—The Highways Committee have reported to the Urban District Council that, as authorised, they had had the electrical appliances at the baths examined by Mr. Vaudrey, C.E., of Birmingham, who stated that the fittings were in a fair condition, and the committee stated that in view of Mr. Vaudrey's recommendations they had instructed the clerk to give Messrs. Fowler and Lancaster notice requiring them to put in new accumulators in accordance with their contract and, failing compliance therewith, they had requested the Baths Sub Committee to obtain tenders for the necessary renewal of the plant and alterations at a cost not exceeding £200 The report was adopted.

Lancaster.—Mr. Jackson, in moving the adoption of the minutes of the Lighting Committee at the last meeting of the Town Council, said there had been one or two important matters. They had decided to erect new lamps in different portions of the town, and these lamps were not only necessary but they would get some revenue from them They would have been glad to do more, but their funds would not allow them. They had proved this year the cost of electric light as compared with gas, and he might say that it had taken rather more than one-sixth of their revenue to light the portions of the town that were so excellently lighted by electricity. The minutes were confirmed.

Cheltenham.—The Town Council have received a letter from the directors of the gas company declining the suggestion of the Lighting Committee for a conference on the question of the sale of their undertaking, and stating that their determination was to oppose to the utmost the Corporation's proposal to purchase. Alderman Norman remarked that the number of 8-c.p electric light lamps for which applications had come in was 5,120 4,300 of which had already been wired, and the remainder of which it was hoped would be wired within the present week. He added that the success of the light had exceeded his anticipations, and the undertaking was now in a condition to bear all the expenses connected with it.

Kingswood (Bristol).—The Chairman of the Urban Council said at the last meeting that he did not know whether they had seen the announcement of the electric light company's intention to apply for a provisional order for supplying public and private electric lighting in the districts of Kingswood and St George. He would like to point out that if that provisional order were granted it would give the company authority to supply the

Digitized by Google

electric light to private consumers throughout the district of Kingswood, as covered by the Urban Council. As the matter was one that interested them a good deal, he thought it would be as well to get legal advice thereon. The chairman's suggestion was eventually adopted.

Newcastle-on-Tyne.—At Wednesday's meeting of the Town Council Mr. Forster asked if anything had been done towards calling a statutory town's meeting for the consideration of the lease for the cable tramways. The Mayor said he thought it might be possible to hold such a meeting about the first week in January. Mr. Forster intimated that as the matter was causing a good deal of interest in the city he had decided to go to Bristol next week to see the different systems at work, and he would be glad if any gentleman would accompany him. Several special members were elected to the standing committees of the Corporation, and it was agreed to appoint a special committee to consider the desirability of the Corporation undertaking the provision of electricity.

Hendon (Middlesex).—The Works Committee of the Urban Council have reported the receipt of a letter from the secretary of the General Post Office intimating that if the Council were prepared to waive their stipulation that iron telegraph poles should be used for the extension of telegraphs to The Hyde, the Department were now in a position to provide the desired communication, the line to be constructed from Chapel path along Burroughs-lane and Edgware-road. Having regard to the great need for the proposed telegraphic communication, the committee recommended that, provided iron poles be used in the line of telegraph from Chapel-street to Edgware-road, the Council would waive the stipulation for their use in the remaining length. The recommendation was approved.

Prudential Assurance Company.—Although the plant for generating the current at this Company's London premises is still in excellent working order after 10 years' work the rapid increase of the Prudential Company's business has made it necessary for the Company to instruct Messrs Drake and Gorham to remodel the general apparatus throughout, substituting plant of a more compact nature. Owing to the results which have been attained by the use of slow-speed apparatus, Messrs. Drake and Gorham have decided to keep to this class of plant, but to dispense with all belt and gearing. The engines and dynamos, built on one shaft, will run at 85 revolutions per minute. The engines will be of Messrs. Marshall's horizontal type, and the dynamos are being built by Messrs. Crompton.

Grimsby.—Telephony in Grimsby seems to be in a bad way just now, according to a local writer: "Subscribers to the telephone seem to be in a suicidal state just now. No power that can be brought to bear upon the local managers of the company seems to affect those immovable pieces of responsibility—not even mild swearing along the wires. The sort of thing that goes on might be almost classed as tragic, for those who rent the instruments are at their wits' end to know what is to be done next. Threats have been used, gentle persuasion has been used, curses have been indulged in, love messages and sweet words have been sent to the fair voice at the exchange, everything in creation has been tried, but the telephone still hangs upon the wall to all intents and purposes a mockery—so say the unhappy subscribers."

Fareham (S. Hants).—Thus a local journal: "What will be done in regard to the Fareham electric lighting works? The judgment given in the Court of Queen's Bench means that the District Council must either pay the electric light company £3,800 damages for breach of contract or proceed to carry out the undertaking entered into by the defunct Local Board to take over the works, which undertaking was, after all, binding upon the Council. To the majority of the councillors, whose repudiation of the contract has brought about this condition of affairs, it is but a choice of evils. Some of them are already expressing an opinion that it would be cheaper in the long run to pay the £3,800 damages and leave the electric light alone. The matter is one in which it would be wise to consult the ratepayers, who will have to pay the piper in either case."

Hull.—The Electric Light Committee has been considering the possibility of extensions in connection with the Board of Trade's new regulations. The Corporation have already spent in Hull in mains nearly £19,000, and if the use of the new higher voltage lamps is not permitted by the Board of Trade, another sum equal to this will have to be expended very shortly in order to double the size of the mains to meet the requirements of new consumers, whilst if the Board permit the use of such lamps, double the quantity of lamps may be used without one farthing extra being spent on mains; and also all future extensions in the town will participate in similar savings, the amount of which in the future must be several thousands of pounds saved to the town. Twenty applications for the supply and extension of the light to consumers were also dealt with.

Bromley (Kent).—The Urban Council have received a letter from Messrs. Waterer and Dickins, declining, on behalf of the syndicate, to pay any portion of the enquiry fees as to the electric lighting, and asking for certain plans. The Chairman said, as he understood the letter, it meant that if the Council would make them a present of £300 they would do certain things in connection with the opening of the roads. The syndicate really asked that the provisional order be handed over to them to carry out, and this he thought objectionable. Mr. Davis thought there might be a competing set of ratepayers who might be aggrieved at the order powers being handed over to this syndicate. The Chairman said the better plan might be to ask the syndicate to nominate a deputation to meet the Electric Lighting Committee of the Council, and this was agreed to.

Ipswich.—The Town Council have considered a communication from the County of London and Brush Provincial Electric Lighting Company, Limited, Mr. Paris, the representative of the company, attending. The Mayor said the application from the company was that the Council would consent to a provisional order for powers to light the town of Ipswich, but neither the Council nor any committee appointed by the Council could possibly have had sufficient opportunity for considering the order or the advisability or inadvisability of consenting to the application. After some discussion, it was decided that a special committee should be appointed to make full enquiries as to the best course to be adopted for the electric lighting of Ipswich, and to report at an early date.

Llandudno.—At the annual meeting of the Llandudno Marine Drive Company a heated discussion took place on a recommendation in the report of the directors for the sale of their undertaking to an electric tram company for £12,500. The report added that the gross receipts for tolls during the year amounted to £663, and a dividend of 11s. per share was recommended. The chairman (Mr. T Williams) moved the adoption of the report. He said he was in favour of selling the drive, because he thought another company would make their famous drive more beneficial to the district. The report of the directors was carried by a large majority. As we intimated last week, the District Council have received several applications from syndicates to lay a system of trams in the town and district, and have decided to get the report of an expert as to lighting Llandudno by electricity.

York.—The City Council have adopted a resolution that the services of Prof. Kennedy, F.R.S., be retained as electrical engineer to the Corporation, the professor (1) to submit a comprehensive scheme for the lighting of the city, with estimates of costs, annual expenses, and probable income, to confer, when necessary, with the committee, and to support the scheme before the Local Government Board, for a fee of 100 guineas and out-of-pocket expenses; and (2) the professor to accept the appointment of engineer of the Corporation electric lighting undertaking, and to prepare detailed plans and specifications, and to supervise the execution of the work, for a commission of 5 per cent., and the fee of 100 guineas to merge in the same commission. Alderman Agar, in moving the adoption of the minutes, stated that the terms for the engagement of an electrical engineer had been accepted by Prof. Kennedy.

Gloucester.—Alderman Langley-Smith, referring to the scheme for electric lighting in the city, said at the last City Council meeting that he noticed that it was only proposed to take the electric light from the Cross as far as Hare-lane in Northgate-street; from the Cross to the Shire Hall in Westgate-street; and from the Cross down to Commercial-road in Southgate-street; and a short distance along Eastgate-street. He supposed that the Council in adopting such a course were actuated by good reasons, but it seemed to him that if such a schame was carried out it would be a waste of money. If they were going to have electric lighting at all, why not light the whole city? The Mayor said that before they got a provisional order they must state the minimum distance they were going to cover. They were naturally anxious to keep their responsibilities as small as possible until they had obtained the provisional order, when, if they thought it expedient, they could light the whole city.

London and Provincial Traction Company, Limited.—This Company has been registered, with a capital of £100,100, divided into £10,000 7 per cent. cumulative preference shares of £10 each and 100 ordinary shares of £1 each. Objects: to enter into or acquire by purchase or otherwise and carry out contracts or concessions or other grants in Great Britain or in any part of the world for constructing or purchasing and working of rail or tram roads, telegraphs, telephones, electric, hydraulic, or other works; and for the equipment of any such undertakings or works, with electric or other plant, stock, and apparatus; and generally to carry on business as general contractors in any part of the world. The signatories are: D. Parrish, 2, Copthall-buildings, E.C.; A. Parrish, 2, Copthall buildings, E C.; T. Wernher, 128, Bishopsgate street Within; T. R. Harris, 15, St. Swithin's-lane, E.C.; S. Neumann, Warnford court, E C.; L Hirsch, Warnford-court, E.C.; H. R. Batin, 6A, Austin Friars, E C.

Tunbridge Wells.—"Shopkeeper" writes to a local paper regarding the electric light: "I have just received the account for lighting my shop for quarter ending September 29, which comes to the sum of 4s 9d. May it ever be thus proportionately moderate!" It is stated that applications are coming in so rapidly for the electric light that the capacity of the central station is already nearly taxed to its utmost limits. It has, therefore been decided to at once proceed with the enlargement, ann the borough surveyor has been instructed to prepare plans for an additional building, and the orders for another boiler, engine, and dynamos have this week been given to be pushed forward with all speed. A good deal of misconception as to the new light is being removed, and it is now being generally understood that the electric light fittings are as cheap as, and in many cases considerably cheaper than, gas fittings, while the light itself is as cheap as gas, and by careful use proves more economical in actual cost. It is understood that the electric lighting of the Pantiles will be put in hand by the Town Council before long.

Wakefield.—Mr. G. W. Willocks, M.I.C.E, has held an enquiry at the Wakefield Town Hall relative to an application to the Local Government Board by the City Council for permission to borrow £25,000 for providing electric lighting. There was no opposition. Mr. Robert Hammond, of London, has been consulted by the City Council, and is to superintend the erection of the

Digitized by Google

proposed works. The site is at Calder Vale, and they are to be carried on in connection or combination with the proposed sewage works. The high-tension current generated in the works is to be conveyed by cable in 5in. cast-iron culverts through Calder Vale-road, Kirkgate. Westgate, Silver-street, Northgate, etc. The estimated cost of the plant is £15,280. It is expected that when the works are completed the County Council will introduce the electric light into their new offices, the asylum authorities into that institution, the Board of Guardians into the proposed new infirmary at the workhouse, the School Board into the proposed new schools in Ings-road, and it is believed that the cathedral the theatre, and opera house, and other public buildings will use it.

Electrolytic Zinc Production.—At the statutory general meeting of the Smelting Company of Australia, the *Financial News* says, Mr. Alfred Fowler stated that the operations of the company would produce a revolution in the treatment of refractory ores. It is proposed to treat all classes of ore, but more particularly the refractory sulphide ores of which there is practically an inexhaustible quantity at the Broken Hill and other mines. Various processes will be used, including the electrolytic process for the recovery of zinc and the preparation of zinc oxide. With reference to the latter, before purchasing the patent rights Messrs. Siemens Bros., and Messrs. Siemens and Halske, of Berlin, had erected plant in Berlin to treat zinc ores and sulphide ores from Broken Hill on a commercial scale The Smelting Company of Australia, therefore, has purchased a process which has to some extent been demonstrated, and has only got to erect exactly similar appliances to those now in use in Berlin. The problem of producing metallic zinc from refractory ores is said to be solved by this invention, and the future of the company will therefore be watched with some interest

Lead-Powder Accumulators have recently been brought on the market by the Elektrizitäts-Gesellschaft Gelnhausen, m b. H. In these the active material of the electrodes consists of a mixture of mechanically-produced lead powder with neutral bodies of porous structure. As electrode supports patented strips of compressed lead are used. The admixture of the porous bodies has the result that the conversion of the lead peroxide into lead sulphate is quickly and uniformly effected throughout the whole material of the electrode, and therefore all deposits of the active material on the delivery of the current are brought into chemical work. It is claimed that through this more uniform conversion into lead sulphate, not only is crumbling of the active material prevented and the potential fall delayed, the efficiency being therefore increased, but also the accumulator is made indifferent to deep discharges and discharges at high intensities of current. For this reason the firm state that the lead-powder accumulator is particularly adapted for portable purposes in which deep discharges and discharges with considerably increased current strengths are frequently unavoidable. The firm is licensed to utilise the Faure patent.

Huddersfield —Mr. G. W. Willcocks, M.I.C.E., has held an enquiry at the Council-chamber, Huddersfield, into an application of the Corporation to the Local Government Board for permission to borrow £50,000 for the purpose of extending the system of electric lighting. The Town Clerk (Mr. F. C. Lloyd) stated that the Corporation had already borrowed £50,000 for the construction of works and supplying electricity in a prescribed area. With the exception of £3,000 which would complete works on hand, the whole of the money had been spent. There were at present 256 consumers and 36 applicants requiring supplies. The lights required by consumers and applicants amounted to 22 050 8 c p. lamps. There was a large demand for the electric light from districts outside the prescribed area, and it was estimated that altogether provision should be made for 50,000 8-c.p. lamps, to secure which the present application was being made. The Mayor (Alderman J. L. Walker) supported the application, and said he believed it would be found remunerative to supply the residential districts with the electric light, because of the night consumption. Mr. A. B. Mountain (the borough electrical engineer), Alderman Calvert, Mr. C. Adkinson, and Alderman J. J. Brook also gave evidence.

Eccles (Manchester).—The last minutes of the Town Hall and Electric Lighting Committee of the Town Council contained the following references to the electric lighting scheme and resolutions passed by the committee; "That in this Council's opinion it is not desirable to allow any company to come into the borough for the purpose of establishing electric lighting, and that the Council, therefore, be recommended to themselves proceed with the scheme rather than risk the possibility of power being granted to a company, as has occurred in other places where the Council have not taken that course"; and "that the Council be recommended to accept the tender of the Manchester Edison-Swan Company, Limited, for the carrying out of the works of electric lighting therein described, according to the specifications thereto annexed, at the sum of £13,792, and subject to the Local Government Board granting to the Council borrowing power adequate for the carrying out of the whole scheme of electric lighting." The committee also sent up a resolution recommending the Council to apply to the Local Government Board for power to borrow £20,000 for the purpose of carrying out the scheme At the termination of the other business the Council resolved itself into a General Purposes Committee in order to confer with the electrical engineer on the subject, and agreed to consider the suggestions and resolutions of the committee at a future meeting.

Bristol.—The Bristol Chamber of Commerce have discussed the National Telephone trunk line tolls. With reference to the joint memorial signed by the Cardiff, Newport, Swansea, Birmingham, and Bristol Chambers of Commerce, addressed to the National Telephone Company, Limited, it was reported that the general manager of that company had had an interview with the Newport Chamber and had explained that their trunk-line traffic had so largely increased that, in order to obviate the complaints of the public as to delay in getting through, the company had had to pay the Post Office charges. These were higher than their own, and had in turn to be charged to the public, and it was easy to see how the complaint arose. However, yielding to the representations of the chambers interested, Mr. Gaine was prepared to go back at once to the old charges, and abandon the use of the Post Office trunk line, if it was to be understood that the public would no longer complain of any delay arising from the crowded traffic, although Mr. Gaine thought that any change now would not be worth while, as the Government were to take over all the trunk-line business of the company on January 1. It was also reported that the Newport Chamber did not consider it worth while to press the matter further, but preferred to wait the incoming of the New Year. Upon the suggestion of the president, it was resolved to concur in the opinion of the Newport Chamber, and defer further action for the present.

Cardiff.—A deputation has attended from the Castle Arcade Company for the purpose of urging that the Corporation, through the Public Works and the Lighting Committees, should defray two thirds of the cost of repaving with stone the Arcade upon the laying of the electric light cables. It was pointed out that the company already paid rates and taxes in respect of their property, but did not get the same return as the ratepayers in St. Mary-street. The property was assessed to its full value, yet the company paid for the maintenance of the pavement and kept its own constable. Mr. Morgan said the company were anxious to get the electric light into the Arcade. That would necessitate a large amount of cutting up the existing cement pavement, and the expense of repair would therefore be heavy. They were anxious to relay the Arcade with stone, and the company would be able to utilise one-half of the Arcade while in the other half the work was in hand Councillor Morgan said it depended upon the amount of return the Corporation were likely to receive from the tenants of the Arcade whether they would be prepared to expend any public money there. It was resolved that the matter be laid by Councillor Morgan before the Lighting and Electrical Committee. The town clerk has reported to the Finance Committee that the Local Government Board had issued an order giving their consent to the Corporation borrowing £12 885 for the purposes of electric lighting, to be repaid with interest within 25 years.

Belfast.—On the report of the Electric Lighting Committee coming up in the Town Council, Councillor Masterson said reports were in circulation that the electrical machinery was not in a very good order—that, in fact, it was dangerous; and Councillor Woodside remarked that the electric plant was driven by gas-engines, and he did not think that was the most economical way. Councillor Wm. M'Cormick understood that no more current would be available when some orders which were in hand had been filled up. Alderman Pirrie, in reply to Councillor Masterson, said the machinery was recommended by Prof. Kennedy, who was one of the ablest electricians they had got. The contract was quite clear, that the engine was to be worked for 12 months, with a guarantee that at the end of the year, if not satisfactory, proper machinery should be put down. Any defects there were were mechanical, and they need not feel the least danger of their being short of light owing to the plant. As to the point raised by Councillor M'Cormick, he had to say that the committee were hampered and confined to a piece of ground hardly larger than that Council-chamber. They had not up to the present failed to supply any customer, and he hoped the committee would put before them such a scheme which would show that they were prepared, not only to keep the electric light before the public, but to make the Gas Committee give them, as they were now doing, better light. The report was carried.

Killarney.—Mr. J. Calvert, the auditor, has given his decision in reference to the payments made by the Commissioners under the heading of public lighting to the gas lessees and the Killarney Electric Lighting Company respectively. In the course of his judgment the auditor said: "Mr. Huggard, on behalf of the electric lighting company, made a very strong point in reference to the proceedings that Mr. Santry's tender should have been accepted by the act of affixing the Commissioners' seal, and further that only Mr. Santry's amendment was put to the meeting. I quite agree with Mr. Huggard that this would have been the correct thing to do; but I cannot agree with him in his contention that it renders the acceptance of Mr. Santry's tender null and void. A contract is an agreement between the parties that one of them shall do or perform some act or acts, or shall abstain from doing some act or acts. In this case Mr. Santry tendered or offered to do a certain thing—to light the town of Killarney for three years—and the very fact of the Commissioners accepting that tender, as I hold it was legally accepted, by the record of their proceedings at their meeting on September 18, 1893, binds them to Mr. Santry irrevocably for a period of three years, so long as he, on his part, carries out his contract. I therefore hold that Mr. Santry's tender was legally accepted, and that any further contract that was entered into by the Commissioners for lighting the town was illegal and unwarrantable, as a contract was already in existence."

Ogwen (N.W.).—The District Council have received a letter from the town clerk of Bangor stating that it was the intention of the Corporation to include in their license for the electric lighting scheme portions of Llandegai and Pentir, and in order to enable the Corporation to do so it was necessary that the Ogwen District Council should consent to the application. The Chairman, in reply to Lady Penrhyn, said that it would be no expense upon

Digitized by Google

the parish. Mr. Richard Griffith, Cororion, proposed that the matter be adjourned for a month so as to give them time to consider it. The Chairman said that the town clerk of Bangor had enclosed the following formal resolution, which the District Council should adopt: "That the application to the Board of Trade by the mayor, aldermen, and burgesses of the borough of Bangor for a license under the Electric Lighting Acts of 1882 and 1888 having been considered and approved by the Ogwen Rural District Council, being the legal authority having jurisdiction within the parishes of Pentir and Llandegai, which form part of the proposed area of supply, the consent of the said Council is hereby given to the application." Mr. W. Roberts, Maesygroes, considered they would be stultifying themselves by giving such consent, as it would debar any other promoters from starting a scheme in the parishes, and perhaps by such competition the electric light would be supplied cheaper. The motion was then carried, and it was decided to communicate with Colonel Sackville West, the chief agent of the Penrhyn estate, as being one who would be largely interested in the matter, saying that the question had come before the Council, and inviting his observations thereon.

Hampstead (London).—The Lighting Committee of the Vestry have reported that it was not desirable at present to light High-street, Rosslyn-hill, and Haverstock-hill with either electric arc or incandescent gas lamps. The report was adopted. The same committee also reported that, pursuant to the authority delegated to them they had given instructions for a distributing main to be laid in Holly-hill, from Heath-street to The Grove, at an estimated cost of £56.—Approved. The Lighting Committee recommended that the necessary mains and transformers for the supply of electric current to provide consumers be laid down in the undermentioned roads, as shown on plans submitted—viz., Frognal, from Arkwright-road to Frognal House, at an estimated cost of £258; Fellows-road, £548; Willoughby-road, £143; Dennington-park-road, £128; Fairhazel-gardens Goldhurst-terrace to Greencroft gardens, £152; Chislett road, Priory-road (from Chislett-road to Canfield-gardens), Canfield-gardens (from Priory-road to Fairhazel-gardens), and Fairhazel gardens (from Canfield-gardens to Greencroft-gardens), £916; and Greencroft-gardens (from Fairhazel-gardens westward to Gleniffer). £128.—Adopted. The chief engineer was authorised to fix circulating water-pipes on the engines for the purpose of cooling the crank chambers, at an estimated cost (including a tank under steps in boiler-house, connections to water-pipes, suction ditto, and pumps) of £95; and he was also empowered to obtain house-connecting cable, T-joint boxes, and sundry articles required at the station, as provided for in the estimates for the year 1895 6, at an estimated cost of £98. 0s. 6d., and to obtain, and keep on stock, a spare arc armature. The Vestry Clerk said that he had received a letter from Mr. Robson, the Willesden surveyor, stating that the Willesden District Council were not at present prepared to consider the subject of lighting the High-road, Kilburn, by electricity. The letter was referred to the Lighting Committee.

Dublin.—Deputations from the Dublin United Tramways Company and the Southern District Tramways Company have been received by the Corporation. Dr. Carte read a statement as to the desires of the Dublin United Tramways Company. The time had now arrived when they should still further pursue the policy of extensions, and, as no doubt they were on the eve of a revolution in the system of traction by electric power replacing horses, the moment had come to propose for consideration a scheme of extension which should satisfy the needs of the city and suburbs of Dublin for some time to come. Dr. Carte then went through the proposed lines seriatim. Mr. Clifton Robinson then addressed the Council on the part of his company. They were an electrical company, and had control of a main line from which they proposed to conduct lines to four cardinal points in the city. They would do this without in any way interfering with their neighbours or duplicating their lines. They offered electrical lines unattended by the detriment and disadvantage of converting an existing horse line and the interruption of public traffic that would be thereby occasioned. Their lines would go through streets which had been hitherto unoccupied and neglected. They believed there was a great future in store for electricity as a motive power; but they did not want to force any particular method of traction on the citizens. They proposed to introduce the transfer ticket system, which had been in use for years in America and on the Continent of Europe. Alderman Meade moved that the letters received from the two companies and the statement read by Dr. Carte be referred to a committee of the whole house with power to confer with the representatives of the companies, the committee to report to the Council, and this was adopted Last Saturday a numerous company, including several members of the Corporation, assembled by invitation at the works of the electric tramway company, in Shelbourne-road, for the purpose of having a run to Kingstown on the electric tramway and of judging for themselves of the extent of its accommodation and of its adaptability for its purpose. The car was in charge of Mr. J. Clifton Robinson, C.E., managing director. The trip was a distinct success.

Sheffield.—In connection with the scheme of the London and Provincial Tramways Company the formalities consequent upon the application to Parliament for powers to take over the tramways in Sheffield and to extend the service into the neighbourhood have been complied with. Copies of the plans of the lines and sections have been deposited with the clerk of the peace for the West Riding, with the town clerk of Sheffield, the parish clerk of Sheffield, the town clerk of Rotherham, the parish clerk of Rotherham, the clerks of the Rawmarsh District Council and of the authorities in Handsworth, Ecclesfield, Greasborough, Tinsley, and Brinsworth. Copies were also lodged with the city surveyor, Mr. C. F. Wike. In London similar copies were deposited with the Board of Trade, at the Private Bill Office in the House of Commons, and in the parliamentary offices. Since the question of traction for tramways has been under discussion in the *Sheffield Telegraph*, the attention of one of the representatives of that paper has been drawn to a system of electrical propulsion patented by Mr. W. Aldred, of Brightside Bank, Sheffield. The fundamental idea of the system is that of the third rail, but it is modified by the substitution for the live rail of contact points, upon which a bar brush, suspended beneath the car, acts for the completion of the electrical circuit, and the production of the consequential motion. The abridgment of the patent gives this brief description of the system: "The two rails, one of which is electrically bonded to form a continuous rail, and the other of which has its sections insulated from each other, are used in combination with a central rail insulated in sections for the purpose of transmitting the current from the dynamo to the car. For every section there is a switch which, when closed, connects the mains from the dynamo to the rail from which current is taken by the car. The switch is closed by means of an electro-magnet excited from a battery carried on the car, the battery being connected to the electromagnet of each switch in succession through the centre rail and one of the side rails" Mr. Aldred exhibited to the representative a number of documents in connection with his patent, including a complete provisional specification. It is numbered 5,391, of 1894, the date of the application was March 15, 1894 the complete specification was left on December 17, 1894, and was accepted on April 13, 1895. He also called the attention of the reporter to two recent issues of the *Electrical Engineer*, containing an account of the Westinghouse underground system for electric traction. This system, Mr. Aldred said, was identical with his in its essentials.

The South Staffordshire Tramways—Mr. W. Somers S. Schuster, chairman of the South Staffordshire Tramways Company, Limited, has addressed the following letter to the *Birmingham Daily Post*: "Sir,—Up to the present time the attacks upon the South Staffordshire Tramways Company which have appeared in the columns of certain papers circulating in Birmingham and its suburbs have been anonymous, and have been therefore disregarded by the Board, although in various instances the name of the contributor and his real objects were well known to them. Now, however, a letter has appeared signed by Messrs. Duignan and Elliott, and addressed to the various local authorities, the object of which is apparently to secure the refusal of the renewal of the company's steam license, a refusal which would have a prejudicial effect upon the prospects of the company. It would be interesting to know the names of the 'people' who, according to Messrs. Duignan and Elliott, are anxious to come forward and put down unlimited funds, not only to equip the lines, but to pay all the liabilities of the tramway company. Messrs Duignan and Elliott have never forwarded to the Board any such proposal. The directors have only one object in view—viz, to do the best they can for their proprietary and the travelling public. One thing, however, I do desire to make clear, and that is that a refusal of the steam license, so far from forcing the hands of the directors, will only have the effect of complicating matters generally, of further damaging the credit of the tramway company, of turning out of work a large number of hands at a season of the year when bread is most needed, of causing a vast and needless amount of inconvenience to the travelling public by stoppage of the cars; and those who have considered the question from an engineering point of view know that it would be quite unreasonable to commence work of the character required at this season of the year. As the safety of our engines has been called into question in previous letters, I desire to take this opportunity of stating that, so far from their being in any way in a dangerous condition, those portions of the boiler which showed signs of wear have recently been renewed at considerable expense, and are certified as safe by the insurance company at full pressure. It is also gratifying to the directors to be able to state that since the appointment of their new manager the traffic receipts have increased, and the expenditure decreased, so that the general prospects of the line are daily improving." The Stoke Town Council have received a letter from the Board of Trade enclosing a copy of a communication which the Board had received from Mr. H. C. Godfray, solicitor, and stating that in the circumstances mentioned the Board had decided to consent to the use of steam power for a further period of six months. The Highways Committee, having read the joint report of the surveyors of Burslem, Fenton, and Stoke, reported that they were of opinion that the system of overhead traction proposed by the North Staffordshire Tramways Company was the best means of traction which could be adopted at present in this borough, but before giving formal consent thereto recommended that the town clerk be instructed to put himself into communication with the other authorities with a view to a combined course of action being taken, and that the question of the settlement of the terms of the proposed agreement with the tramways company stand over. This was agreed to, and a sub-committee appointed.

PROVISIONAL PATENTS, 1895.

NOVEMBER 25.

22505. **Active material for electric accumulators.** Fritz Dannert, Hermann Windolff, and Johannes Zacharias, 40, Chancery-lane, London. (Complete specification.)

Digitized by Google

22480. **Improvements in dynamo-electric machines.** Henry Chitty, Hogarth Works, Chiswick, London.

22506. **Electric accumulator.** Fritz Dannert, Hermann Windolff, and Johannes Zacharias, 40, Chancery-lane, London. (Complete specification.)

22511. **Improvements in the production of bulbs for incandescent lamps.** Otto Max Constantin Heyl, 37, Chancery-lane, London.

22519 **Improvements in or connected with electric railways or electric transport.** Frederick Carleton Esmond, Norfolk House, Norfolk-street, London. (Date applied for under Patents, etc., Act, 1883. Sec. 103, April 26, 1895, being date of application in United States.)

NOVEMBER 26.

22543. **An improved carbon-holder for electric arc lamps and projectors.** George Wilson, Bryntirion, Glandare-road, Aberdare.

22569. **Improvements in or connected with electric bell-pushes.** James Withers Creasey and Thomas William Breach, 23, Coleman-street, London.

22574. **Improvements in the manufacture of insulating compositions for electrical purposes.** Charles James Grist, 55, Chancery-lane, London.

22586. **Improvements in single-phase alternate-current motors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

22600. **Improvements in and relating to a system of telegraphic communication.** Isidor Kitsée, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

NOVEMBER 27.

22660. **Apparatus to protect against danger from overhead electric wires.** William Thomson (Baron Kelvin), 154, St. Vincent-street, Glasgow.

22661. **Improvements in apparatus for indicating and recording electric supply.** William Thomson (Baron Kelvin), 154, St. Vincent street, Glasgow.

22679. **Improvements in the construction of electric light fittings.** George Wadely, 19, Southampton-buildings, Chancery-lane, London.

22686. **Improved automatic electromagnetic interrupter for protecting electrical installations.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (Compagnie pour la Fabrication des Compteurs et Materiel d'Usines à Gaz, France.

22696. **Improvements in alternating-current arc lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Wilhelm Mathiesen, Germany). (Complete specification.)

22717. **Improvements in telephonic apparatus.** Maxymilian Kotyra and Charles Milde, 45, Southampton-buildings, Chancery-lane, London.

NOVEMBER 28.

20925A. **Improvements in or relating to incandescent electric lamps.** Edward Burnet, 6, Lord-street, Liverpool. (Date claimed under Patents Rule 19, November 5, 1895.)

22732. **Improvements in a process and apparatus for the electrolytic production of metallic zinc from ores of zinc, and metallic zinc and metallic copper from zinc ores containing copper, and the production of oxygen gas in the cases specified.** Charles Anthony Burghardt and Gilbert Rigg, 35, Fountain-street, Manchester.

22736. **Improvements in electrical separators.** Silvanus Phillips Thompson and Miles Walker, Morland, Chislett road, West Hampstead, London.

22783. **An improved attachment for telephone receivers.** John Danaher Greene and Benjamin Warne-Browne, 2, Newcastle-street, Strand, London.

22793. **Improvements in and relating to electric vapour engines for vehicle and launch propulsion in particular.** Walter Rowbotham, 52, Wheeley's-road, Edgbaston, Birmingham.

NOVEMBER 29.

22846. **Improvements in and connected with automatically-operated electrical switches.** Frederick George Robinson, 10, St. George's-crescent, Liverpool.

22860. **Telephone communicating system for expediting messages.** Peter Ferguson, Fish Mart, North Hamilton-street, Kilmarnock.

22864. **Improvements in or relating to telegraphic receivers, especially applicable for submarine telegraphy.** Alfred Piedfort, 323, High Holborn, London.

22866. **Improvements in the extraction of copper from its ores by electrolysis.** Alfred Francis Bilderbeck Gomess, 9, Warwick-court, Gray's-inn, London.

22898. **Improvements in the manufacture of electrical fuse-boards and other like articles.** Richard Thomas Grocott, 18, Southampton-buildings, Chancery-lane, London.

22899. **Improvements in and connected with secondary batteries.** John Ebenezer Bousfield (of the firm of G. F. Redfern and Co.), 4, South-street, Finsbury, London. (G. Dorville and Co., France).

NOVEMBER 30.

22936. **Improvements in and connected with electrical commutators and collector rings and collectors therefor.** Thomas Frederick John Truss, 10, St. George's-crescent, Liverpool.

22939. **Improvements in electrical sounding apparatus.** Francis Gwyn Griffith, 22, Southampton-buildings, Chancery-lane, London.

22985. **A contact device for the transmission of electric current.** Carl Bremer, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22987. **An improved electrical lamp and battery, especially applicable for use in bedrooms, but applicable for various other purposes.** Mary Margaret Harris and Gerald Guthbert, 16, Lollard-street, Lambeth, London.

SPECIFICATIONS PUBLISHED.

1882.

224. **Electric lighting etc.** Lake. (Williams.) (Second edition.)

1892.

5652. **Conduits.** Lake. (Thomson-Houston International Electric Company.) (Second edition.)

1894.

15192. **Electric, etc., railways.** Sayers.

21489. **Electrical apparatus for working railways.** Deming.

22866. **Telegraph instrument.** Morriss.

23529. **Electric switches.** Lyon and Bevis.

23825. **Arc lamps.** Brockie.

23854. **Electrical distribution.** Wood.

24907. **Arc lamps.** Blackburn and Fairall.

1895.

298 **Electric vehicles.** Claret and Vuilleumier.

351. **Arc lamps.** Gwynne and Kennedy.

523. **Lightning arresters.** Belfield. (Westinghouse Electric and Manufacturing Company.)

1714. **Electric glow lamps.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

1717. **Electric accumulators.** Pirsch.

2650. **Electric bells or gongs.** Quincey.

3003. **Regulating electric motors.** Thompson. (Lauhoffer and others.)

NOTES.

The New German Safety Rules will shortly be published. The commission entrusted with the task of drawing up the measures has completed a portion of its labours.

The Verband deutscher Elektrotechniker discussed at its meeting on December 7, in Berlin, the question of word-marks in connection with the German Merchandise Marks Act.

Royal Scottish Society of Arts.—At the last meeting of this society, Prof. Armstrong, president, occupying the chair, a communication was read by Lord Kingsburgh on "Electricity in the Household."

A New Cable Across the Yangtze.—It is stated that the Chinese Telegraph Administration has recently laid a cable across the Yangtze to Tsungming, and that telegraphic communication with that important island will shortly be opened to the public.

Electric Cooking and Heating.—At the last meeting of the Hanover Elektrotechnischer Verein, Herr Ingenieur Dr. Hartmann, of Berlin, read a paper on "The Application of the Electric Current to Cooking and Heating Purposes in the Household and in Industry Generally."

Electric Fans for the Navy.—The Admiralty have, it is stated, decided to experiment with electric fans, which will be fitted to the cruiser "Pearl" at Devonport. If the experiment prove satisfactory, it is understood that the "Phœbe" and "Philomel," on the Cape station, will be similarly fitted.

Acetylene.—At the last meeting of the Liverpool section of the Society of Chemical Industry, at University College, Dr. Campbell Brown illustrated the illuminating properties of acetylene, and pointed out various difficulties in the way of using the gas as an illuminating agent; and Dr. Kohn repeated an experiment illustrating some of the causes of the illuminating power of hydro-carbon vapours.

Electric Fog Signalling.—A party of gentlemen, including Captains Wilson and Parke, of the Board of Trade, and Lieut.-Colonel Martindale, has inspected on board the steamer "Dungeness" at the St. Katherine's Dock, London, the improved form of an arrangement designed by Mr. F. H. Berry for automatically giving the bell and whistle signals required of a ship in a fog. The apparatus, by means of electricity, not only sounds the bell or blows the whistle at the necessary intervals, but also leaves a permanent record in red and black inks on a strip of paper of the times at which these operations were performed. Both the frequency and the duration of the signals can be easily regulated.

The Pacific Cable Scheme.—It is announced that the representatives of New South Wales, Victoria, and Queensland, assembled in Sydney, have decided to appoint delegates to the Pacific Cable Conference, probably the Hon. Duncan Gillies and Sir Saul Samuel, the Agents-General in London of Victoria and New South Wales. New Zealand, it appears, was not represented at the meeting, but expressed her assent. It is expected that South Australia and Western Australia will acquiesce in the arrangement. It is stated that the Australian representatives now in Sydney are divided on the question whether the proposed Pacific cable shall start from Queensland or New Zealand.

An Unusual Central-Station Accident.—The *Electrical World* says that at 7 a.m. on the morning of Friday, November 14, an 8in. steam-main burst in the Elizabeth-street Brush Station, New York City, filling the whole station with scalding steam before it could be shut off, which was not until 15 minutes later. The boiler pressure was 110lb., but fortunately the plant had just shut down and the fires were banked. Even in the brief interval during which the steam was escaping havoc was played with the belts, which were scalded so badly as to practically ruin them, only a few which were completely saturated with oil escaping. The leather was in such a brittle condition that it could be fractured by a blow, and all the glued joints came apart or had become so treacherous that it was unsafe to run with them.

Possible Cause of Flat Wheels.—A number of large electric traction companies find that the renewal of flat wheels involves considerable expense. Among the causes which lead to the shortening of the life of the wheel may be the severe arcing that not infrequently occurs between the wheel and the rails. The resulting heating tends to anneal the chilled rim, with the consequence that flat surfaces are produced when the wheel skids. It has been suggested that as a possible remedy for this evil a steel brush pressing on the head of the rail might be used to reinforce the wheel contact. If such a device could be made practicable it would serve a double purpose; it would keep the contact surface clean and reduce the arcing at the wheels by taking a considerable proportion of the current, and at the same time a saving in power would be effected.

Railway Telegraph Routes.—An important judgment has been delivered in the Supreme Court of the United States by Mr. Justice Harlan, who has decided that the contracts and agreements between the Union Pacific Railway Company and the Western Union Telegraph Company, by which the latter was given the sole right to maintain its telegraph lines on the right-of-way of the railroad company, are null and void, and cannot be enforced. The learned judge said that any telegraph company which accepted the terms of the Act of 1866 had the right to place its poles on any postal route of the United States, provided it did not interfere with the railroad company in the operation of its line. The Union Pacific Company, under the terms of the decision, must, he averred, undertake the management of its own telegraph line along the route of its railroad.

Electrical Nomenclature.—Mr. Frederick Walker, C.E., F.S.P.A., read a paper before the Society of Patent Agents at the general meeting of that body on Wednesday on "Electrical Nomenclature and the Classification of Electrical Patents." The main object of the paper was to point out the extension of the general terms used in electrical science, and protest against the classification of the printed specifications at the Patent Office, which were, it was stated, based upon obsolete systems, and rendered what should be a simple search a formidable and harassing undertaking Mr. Horn, F.S.P.A., after the discussion, moved: "That there should be special divisions of the subject-matter indices relating to inventions, and more particularly to electrical inventions, similar to what prevails in the United States and Germany." The paper and this resolution which was carried, form together the subject of a memorial to the Board of Trade.

Accumulators v. Resistance Coils.—M. Albert Nodon, writing in *L'Electricien* of November 30, remarks that the introduction of resistance coils into a circuit must always produce a waste of energy, and in some cases of arc lighting the proportion lost is a serious one. He suggests, therefore, that where it is desired to lower the potential, accumulators should be used and the energy recovered from them. For instance, with two arcs in series on a 110-volt line there would be 30 volts with a six or eight-ampere current available for charging the accumulator.

Digitized by Google

In the case of an alternating current, he suggests that a rotary transformer should be used, and states that this has been done experimentally at Havre with success. It is, however, added that the continual attention that must be given to accumulators would probably prevent their adoption by most people, and that there are, unfortunately, numerous practical inconveniences in the way of their use. Probably, if this were not the case, M. Nodon would not have had an occasion for the suggestions he makes in his article in our contemporary.

The Polarisation of the Light of Incandescent Bodies.—The polarisation of the light emitted by incandescent bodies has not yet been fully investigated. Arago, indeed, made some experiments on incandescent iron, platinum, and glass; but these were only qualitative, and did not extend to liquids. Mr. R. A. Millikan publishes, in the *Physical Review*, an account of some careful tests of light emitted by glowing solids and liquids, with a view to discovering the laws of its polarisation. This phenomenon is exhibited strongly by incandescent platinum, silver, and gold, and by molten iron and bronze. A somewhat feebler polarisation is shown by copper, brass, lead, zinc, and solid iron. The most significant result is that polarisation is minimum with rays emitted normally to the surface, and maximum at a grazing emission. This indicates that the vibrations take place in a plane at right angles to the emitting surface. To show the phenomenon at its best a smooth surface is essential. Glass and porcelain also emit polarised light, but to a less amount. Fluorescent bodies do the same; so that evidently a high temperature is not necessary.

Accumulator Patent Disputes in Germany.—The action which the Akkumulatorenfabrik Aktiengesellschaft in Hagen brought against the Neue Berliner Elektricitätswerke und Akkumulatorenfabrik Aktiengesellschaft (vormals Hirschwald, Schäfer, and Heinemann) for infringement of patent has resulted, it is stated, in a Berlin court deciding that the accumulators of the latter firm fall under the Faure patent, and that the Hagen Company is justified in prohibiting the firm from producing further accumulators of the kind in dispute. The Berlin firm has appealed against the decision, alleging that it can only apply to its predecessors, Herren Hirschwald, Schäfer, and Heinemann. In this connection it is interesting to note that under the title of Internationale Elektricitäts und Akkumulatoren-Gesellschaft, Berlin, a company has been formed, with a capital of 4,200,000 marks, which proposes to exploit 10 foreign accumulator patents, besides the patents of Herren Hirschwald, Schäfer, and Heinemann, according to which, as binding medium of the active material, pure glycerine mixed with butyric acid is used.

Electro-Pneumatic Continuous Brakes.—M. G. Lesourd has described in a paper read before the Socié é des Ingénieurs Civils de France on November 22 the Chapsal electro-pneumatic brake. With continuous brakes worked on either the pressure or vacuum system, when the train is very long, the distribution of pressure will take some time to effect itself, and the braking action will not be simultaneous all along the train. Various devices have been adopted to obviate this, with more or less success. That of M. Chapsal is an electrical apparatus. Two wires for putting on and taking off the brakes run the whole length of the train. These work valves under each carriage, and in the case where the system is applied to the Westinghouse brake the upper part of the triple valve is modified. M. Lesourd illustrated his description by models worked with a cylinder of compressed carbonic acid, but the *Bulletin* gives no detailed description of the apparatus. It was claimed, however, that it was exceedingly efficient, and at the close of his demonstration M. Lesourd was complimented by the president. The Chapsal apparatus, with some modifications, can be applied at comparatively small expense to almost any existing system of continuous brakes.

Storage Batteries v. Gas-Engines.—The communication of Mr. Nelson W. Perry, presented before the last meeting of the American Institute of Electrical Engineers (the New York *Electrical Age* of November 30 says), states in plain terms the author's opinion regarding the use of storage batteries for the purpose of relieving electrical systems of the strain due to sudden and violent fluctuations of load. Mr. Perry prefers the gas-engine to accomplish the desired results where the question of economy is the dominant one. Even where it is necessary to use gas from the street mains, he maintains, it would be more economical to use a gas-engine to take the peak off the load than to instal a storage battery plant for the same purpose. The gas-engine industry in the United States, according to Mr. Perry, is managed in a very incompetent and unintelligent manner. He claims that American manufacturers do not really know what their own engines are capable of doing, and so unsatisfactory is the condition of things there, with respect to these engines, that "recent large orders for gas-engines have gone abroad, where the business is conducted on business principles." Our contemporary considers that this is a serious charge to make, and that if there is the slightest semblance of truth in it, American gas-engine interests should be alive to the situation.

Visible Radiation and Temperature.—A new determination of the lowest temperature at which a hot body becomes visible is published by Signor Pettinelli, in the *Nuovo Cimento*. He heated a cast-iron cylinder 30cm. long and 14cm. broad, in a wrought-iron jacket over a Bunsen burner to a temperature of 460deg. C., as indicated by an air thermometer, and then observed its flat end in a dark room from a point 60cm. above it. When it had cooled to about 415deg. the red heat vanished and gave way to an indefinite hazy glow. This glow completely disappeared at 404deg., and repeated observations gave an error of only 3deg. High emissive substances, such as the mantles made by Auer and others for incandescent gas lighting, became visible at the same temperature, but reflecting surfaces had to be heated 20deg. higher before they appeared to the eye, and glass still more. These low-temperature rays were found to traverse glass and water like ordinary light rays, but they suffer a comparatively greater absorption. Different eyes differ slightly in their capacity for seeing them, the maximum divergence being about 6deg. But the extent of surface must be the same. Signor Pettinelli found that if he screened off all but $\frac{1}{10}$th of the surface, the body had to be heated 6deg. higher than before to become visible.

The Incandescent Lamp Question.—The *Elektrotechnische Zeitschrift* of December 5 contains the full report of the commission which was appointed by the Union of Representatives of Electricity Works in Germany (Vereinigung der Vertreter von Elektrizitätswerken) to investigate the incandescent lamp question. The report is not very satisfactory from several points of view. It states that "the complaints of consumers that the incandescent lamps are bad—good for nothing—are justified." As the causes of this regrettable condition of things it gives: Imperfect sorting, false marking, little economy, and too short life of the lamps. In 70 lamps supplied by eight makers, which were given as 16 standard candle-power, and whose rate of consumption should have

Digitized by Google

been 3·25-3·50 watts per candle-power, the illuminating power fluctuated between 7·82 c.p. and 22·85 c.p. and the rate of consumption between 2·8 and 6·3 watts per candle-power. One of the very first German firms supplied 20 incandescents specially for the investigations. In these 20 the illuminating power fluctuated between 10·21 c.p. and 21·6 c.p., while the consumption in watts averaged 4·1 per candle-power. In 10 16-c.p. 3·5-watt lamps from another first-class firm the illuminating power decreased in the course of 48 hours' burning by from 40 to 60 per cent., while the consumption in watts per candle-power rose on the average to 5·6.

The Hatch Storage Battery.—An exhibition of the Hatch storage battery recently took place in Philadelphia, and the results are said by the *Electric Railway Gazette* to have been entirely satisfactory to the members of the exploiting company. It is stated that the batteries have been successfully used for street car propulsion, and that a car equipped with them has been run continuously for months. The battery was invented by Mr. George E. Hatch, of Quincy, Mass., in 1890, and is covered by United States patents. Since the invention continuous experiments have been made with the battery, both in the laboratory and in practical work. Mr. Hatch uses light, porous earthenware plates, and places the active material upon them, clamping and binding the plates together by means of light wooden boards and flexible rubber bands. Between the earthenware plates are very thin lead sheets provided with lugs at the top which serve to form electrical connection between the elements. The advantages claimed for this method of construction are greater strength, lightness, elasticity—to allow for expansion and contraction—and the positive security and stability of the active material. It is claimed that the battery is entirely unaffected by the jolting of street cars and railway trains, and that extremely heavy discharge rates do not affect its life or cause its depreciation.

Preventing Electrolytic Corrosion.—A correspondent in an American contemporary says that the old scheme of connecting pipes to the negative pole of the dynamo, as advocated by some, gives but slight and temporary protection to the pipes, for electrolytic corrosion will take place when the pipes are even a hundredth of a volt positive. Such advice, he remarks, would cause great loss to any large railway company adopting it, and would be of little permanent value to any gas or water company. It might possibly help the operation of the telephone exchanges, but such help could be obtained in a less expensive and wasteful manner. He fully agrees with Mr. Edison in stating that he knows of but one practical method of stopping the destruction of the pipes, which, at the same time, effects a large saving of power to the railway company adopting it, for, of course, the work expended in reaching, corroding, and leaving the pipes is entirely lost. This is the process used by the Board of Street and Water Commissioners at Newark, N.J., U.S.A. Here the outgoing or positive current is carried to the trolley wire, but the negative terminal of one dynamo is disconnected from the rail return wire and joined to a wire leading to the points on the pipes which suffer the greatest amount of corrosion. The electrical pressure of this dynamo is then increased until the pipes are made two or three volts negative to the rails at the points which were previously positive, and were therefore corroded. As long as the pipes are kept negative to the rails there can be no more corrosion of the pipes, and the problem is solved.

Power Required for Electric Traction.—In an article in the *Sibley Journal of Engineering*, Mr. James Lyman gives the results of a number of tests made in different cities of the power required for electric traction. At Rochester, where the first of Mr. Lyman's records was obtained, there are about 20 miles of track, which was in good condition at the time of the test. The number of cars on the road was 40, each weighing about eight tons, and provided with a 15-h.p. geared motor. In general, the road was level, but in the heart of the town there were some gradients of from 3 to 4·7 per cent. Moving on the level, the necessary tractive power averaged 38lb. per ton of car, and for the whole run over the four principal routes, at 6·5 miles per hour, the average horse-power was 1·4 per car, and the maximum 6 h.p., this latter only being used momentarily. At Buffalo the same average power was required, but the maximum was 6·6 h.p. In a large Western city a car with the axles coupled direct to the motor, without the intervention of gearing, took 0·92 h.p. per ton on the average, with a maximum of 4·7 h.p. In wet weather the tractive power required is reduced, the rain acting as a lubricant. Wetting of the rails round curves is said to be particularly effective, the requisite traction power being thereby reduced by one-third. Comparative experiments made at Ithaca, N.Y., showed that on gradients the tractive force required exceeds that on the level by more than the theoretical amount.

Electrical Opportunities in Japan.—In a recent article in a Chicago newspaper Mr. William E. Curtis states that he has been assured by the Japanese Minister of Agriculture and Commerce that the Government is decidedly against granting to foreigners concessions for any form of transportation or communication, or for any public improvements or conveniences. The Minister explained that the friction between the telephone, electric light, gas, water, railway, street car, and similar companies and their patrons was already becoming troublesome, and that Parliament would very soon be compelled to enact laws similar to those in the United States for the regulation of such enterprises. It would, he added, be much easier to control and restrict them if they were owned by citizens of Japan. Foreigners would naturally appeal for protection to the diplomatic agents of their governments, and perplexing complications might ensue. Therefore, the Ministry, which had given the subject long and serious consideration, had decided not to allow the control of any public works to be placed in the hands of foreigners. There was no objection to the investment of foreign capital in their stocks and bonds, but the management must be strictly native, and laws would probably be passed requiring all directors of such corporations to be subjects of the empire. Numerous companies have been organised for the construction of electric railways in Japan, and many of them will doubtless carry out their plans in the immediate future. One proposes a trolley line in Yokohama, another an extensive system in Osaka, the most enterprising city in the empire and the second in population. Another contemplates the extension of the present trolley line in Kyoto, which is the only one in Japan. Similar enterprises are on foot in Nagoya, Kobe, Nagasaki, and other places. There are also applications before the Government for electric lines between Yokohama and Tokyo, a distance of 18 miles, and between Kobe, Osaka, and Kyoto, a distance of 48 miles.

The Murphy-Pierce Sub-Trolley System.—The electrical railway system devised by Messrs. John M. Murphy and Albert F. Pierce, of Danbury, Conn., is described in the New York *Electrical Engineer* of November 27. It dispenses with the overhead wires and the conduit underneath the car. The surface only of the road is used, and the car takes the power from the section of

Digitized by Google

rail directly beneath it. Between the rails on which the car runs is a third rail, laid in short sections, each section being perfectly insulated from every other section. The car, in passing, automatically engages the section of this third rail directly beneath it, and from it takes the power. This is done by one wheel of the car which touches a push-pin, thus operating mechanism placed underneath the rail, which in turn makes the connection with and charges the section of rail over which the car is passing. As the car moves forward and touches another pin, the section in the rear is cut out the same instant the one forward is charged. The main or feed wire, insulated, is buried along the outside of the track. From this feed wire, insulated wires run to each section of the rail from which the car derives its power. These wires pass to the section through the mechanism by which the connection is both made and broken. The mechanism is simple, consisting of a lever, a pawl, a wheel, a shaft, and an electrical switch. All of this mechanism is encased in a box cast especially for it, watertight as well as dust-proof. There is a fuse-box between the wire and every section of rail, which makes it impossible to charge the rail up to the danger point. Any more than the required voltage burns the fuse and makes the rail dead. The charged rail is never exposed from underneath the car. All the mechanism used is cast in the foundry, making it comparatively inexpensive, and also possible to replace any part at a moment's notice. The electrical connection is made and broken by mechanical means. There is no magnetic switch device. An experimental section has been laid at Westport, Conn. It will be seen that this system has much in common with others brought out.

The Hargreaves-Bird System of Electrolysis.—A paper on the Hargreaves-Bird system of electrolysis was read on Monday before the London section of the Society of Chemical Industry. The paper was illustrated by one of the cells used at the experimental works at Farnworth. The author showed that by the use of diaphragms a degree of purity could be obtained superior to that yielded by the Leblanc process without the use of such a dangerous and poisonous material as mercury. The possibility of obtaining such results had been denied, and theoretical data given to justify the denial, but, nevertheless, the author said, it was now an accomplished fact. His experiments had led him to the conclusion that ionic migration was not bilateral, but unilateral. To perform the chemical work by direct electrolytic action required less fuel and labour than by the use of a succession of processes requiring the intervention of secondary reagents. The seeming absurdity of yesterday was now becoming a serious competitor to the older system. In the discussion, Sir Henry Roscoe complained of the course taken by Mr. Hargreaves in depreciating the Castner process. His accounts of the mercury lost and the sanitary effects of its employment were gross exaggerations. Dr. Hurter also complained of the spirit in which Mr. Hargreaves had criticised a paper read by him in Liverpool in 1888, and showed that the accepted theories were quite sufficient to account for the results obtained in the cell then exhibited. In reply, Mr. Hargreaves said he had condemned a mercury process of his own, after spending considerable time upon it, for exactly the same reason that he condemned all other mercury processes. The final result, however, was that they had not only done without mercury, but obtained a greater value of products from a given power. The mercury losses quoted were less than those given by Mr. Castner himself. His description of the evils produced by mercury could be supported by volumes of evidence. As to migration theories, the whole question was too nebulous to build any secure hypothesis upon. He gave his own ideas as nothing more than scientific guesses, which might or might not be confirmed in future.

Technical Education.—The Duke of Devonshire presided on Tuesday at the annual meeting of the National Association for the Promotion of Technical and Secondary Education, held at the United Service Institution. The report, which was presented by Sir H. Roscoe, was adopted. The Duke then opened a conference of representatives of technical education committees of county and borough councils. He explained the circumstances which had led to the holding of the conference, and said that its postponement from July had been attended with the effect of converting him from a private and irresponsible individual into a member of the Government, responsible both to his colleagues and to Parliament. This circumstance compelled him to abstain from offering any suggestions which might be construed into an announcement of the intentions of the Government. He hoped, he said, that the conference might give them something in the nature of a review of that part of the question of secondary education which was concerned mainly with technical instruction from the point of view of those concerned in its administration. The conference then proceeded to discuss the subjects of evening continuation schools, scholarships, and trade and technical classes. Lord Playfair, in closing the discussion, said that advance in technical instruction was important to the progress of this country. The prices of almost all machine-made commodities had fallen by 30 per cent. during the last 25 years. This had produced dislocation of labour and want of employment. Depression had been due to the fact that the world had not been able to adjust itself to the wonderful changes science had made in production and distribution. Since 1856 aluminium had fallen in value from 360s. to 2s. per pound. The cost of transport had been so far reduced that the flour in a quartern loaf was brought four or five thousand miles for a halfpenny. We must, he remarked, enable our people to adapt themselves to these changes and so to maintain the position of this country.

The Cantor Lectures on Horseless Carriages.—Mr. W. Worby Beaumont gave the second of his Cantor lectures on "Mechanical Road Carriages," at the Society of Arts, on Monday. After suggesting that among the reasons why in the earlier part of this century steam carriages, in spite of the success achieved with them from a mechanical point of view, failed to establish themselves in this country were the facts that the available capital was being absorbed in railways and the people were not really ready for them, the lecturer proceeded to deal with the development of steam road locomotives and traction engines. It had been thought that the attention paid to these in what might be called the second period of the nineteenth century mechanical carriage enterprise had delayed the development of steam carriages. However that might be, it was true that for many years very little was done towards the production of a comfortable carriage, the energy of inventors being all devoted to the construction of traction engines. The lecturer then described some of the machines which were designed by such men as Worby, I. W. Boulton, Tangye, Aveling, and others. In conclusion, he remarked that at present there was a demand for vehicles to carry goods and passengers, and there was every reason to believe that a really good carriage of not too expensive and complicated a design would be taken up by capitalists willing to invest in its manufacture. In the adjourned discussion on Wednesday evening on the paper read by Mr. H. H. Cunynghame on "Locomotive Carriages for Common Roads" at the Society

Digitized by Google

of Arts, Mr. J. Wolfe Barry, C.B., F.R.S., being in the chair, Mr. Alexander Siemens said that if engineers had a chance they would be able to effect great improvements, provided that the public took the matter up. He instanced the great advances that were made in the supply of electricity after the removal of the comparatively severe restrictions. He thought the problem of constructing heavy vehicles should first be attacked, and suggested the substitution of mechanical omnibuses for the present vehicles. Mr. Yeaman, again, in the light of experiments that had been carried out, saw no reason why electrical omnibuses should not run from Hammersmith to Liverpool-street with accumulators of the types now in use, without relying on some problematical light accumulators not yet on the market; while Mr. Beaumont said it seemed to be assumed that we should easily get existing restrictions removed, but he thought that unless everyone did his best, it was not improbable that a Bill would be rejected.

Electric Mains and Roadways.—At last Friday's meeting of the Institution of Junior Engineers, held at the Westminster Palace Hotel, Mr. H. B. Vorley in the chair, the paper read was on "Urban Roads and Footways, with Notes on Gas, Water, and Electric Mains, etc., in connection therewith," by Mr. J. Julian, of the borough engineer's office, Cambridge. After a few preliminary remarks as to the original laying out of roads, the author considered their formation as executed principally by local authorities before taking them over. In macadamised roads, it was more economical to strengthen the foundation than to use a thick layer of other material between foundation and surface. The materials employed for foundation and, to a somewhat lesser degree, for surface were shown to be governed by local circumstances. Examples of cost in three localities amounted to practically the same per yard super—4s. 3d.—but the problem in most places was, perhaps, to produce a road as good as possible for a fixed figure, the various items varying considerably. Details were also given of the total cost per yard super of pavings on concrete foundations—viz., granite 11s. 9d., hard wood 15s., and asphalte 11s. The limiting gradients in ordinary cases were—asphalte 1 in 60, wood 1 in 25, macadam 1 in 20, and granite 1 in 15, but there were instances of macadam roads as steep as 1 in 6. Channelling, kerbing, and paths were then dealt with, and the common roadwork section of the paper concluded with some figures as to the covering capacity of stone and quantities of granite to the ton. Proceeding then to consider the laying of tramways, it was shown how great was the proportion which the roadwork bore to the other expenses of tramway track construction. A brief description followed of the overhead and conduit electric and the mechanical cable systems, and the underground works of a road were then reviewed. Various modes of laying electric mains were described, and particulars were given as to cost and of methods for determining the size of conductor and other data. Water and gas mains were then noticed, and with reference to them the author presented several formulæ for obtaining first approximations. Details of joints were illustrated, while an estimate for laying a pipe main showed the importance of taking into account the cost of restoring the road surface. Attention was finally directed to hydraulic, pneumatic, and steam power mains. In the discussion which ensued, Messrs. R. W. Newman, E. A. Berry, C. Mittelhausen, S. Boulding, F. Fisher, W. R. Beckton, W. Cooke, and the chairman took part.

Mechanical Road Carriages.—There was a large attendance at the meeting held at the Cannon-street Hotel on Wednesday of those interested in self-propelled traffic and horseless carriages, in order to consider "the advisability of forming an association to deal with a subject which closely affects agricultural, trade, and private interests." Sir David Salomons, Bart., who presided, said that in 1875 he started making an electrical bicycle, but as there was no accumulator the matter fell to the ground. Referring to the recent exhibition of self-propelled vehicles, he stated that he received in connection with it an enormous mass of correspondence. He had collected cuttings on the subject from about 300 newspapers, and 90 per cent. of them were in favour of the new mode of traffic, 8 per cent. were practically neutral and said "wait," and 2 per cent. were adverse on sentimental grounds. If he had been a manufacturer, he could easily have sold many hundreds of these carriages. Opposition to the movement, he asserted, would of course come from two classes—those who would deplore the disappearance of the horse, and those who said that the new vehicles would not want oats. At the present time, however, the foreigner competed with this country as regarded horses, and as to oats, more than nine-tenths of the quantity used was brought from abroad. The money thus expended would be retained for the benefit of our own countrymen if these self-propelled carriages could be made in England. He felt sure that the present Government would look favourably upon the movement. By the introduction of this means of traffic the streets would be clearer and cleaner, and there would not be the present continual demands for new and wider streets, as the block of traffic which caused such demands would disappear. He concluded by moving a resolution expressing the desirability of forming the Self-Propelled Traffic Association, and incorporating it with £1 liability under the Companies Act. Mr. Cumming Macdona, M.P., who seconded the motion, remarked that he went to Paris purposely to see how these motors were made, and he found no fewer than nine large manufactories in full work. A great country like ours ought not, he affirmed, to be in the background in such a matter, but this would depend on Parliament removing the obnoxious Act which prevented us from having the same facilities in this country as those which existed in France, Germany, and America. Mr. Bertram van Praagh said that when they saw those carriages going through the most crowded streets and boulevards in Paris without frightening a horse or disturbing the traffic in any way they must recognise that, sooner or later, they would have an equal hold here, and that if England were not to be left behind they must bestir themselves here. To show what the new machine was capable of he mentioned that the carriage had been driven from Marseilles to La Turbie, and had been got along rough roads, through snow, and up inclines without difficulty. The motion was carried unanimously. The chairman then proposed a resolution appointing an executive, consisting of a president, four vice-presidents, and 30 members, and, on the motion of Mr. G. N. Hooper, Sir David Salomons was appointed president; Lord Winchelsea, Sir F. Bramwell, Mr. Alexander Siemens, and Mr. John Philipson were elected the four vice-presidents if they would serve; and the following gentlemen were appointed members of the council: The Hon. Evelyn Ellis, Sir Albert Rollit, M.P., Sir H. T. Wood, Colonel Mellor, Prof. Boyd, Mr. Jacobs (vice-president of the Institution of Carriage Manufacturers), Mr. Shipton (Cyclists' Touring Club), Mr. Marshall (Gainsborough), Mr. George Stephenson (Newcastle), Sir Richard Tangye, Sir Benjamin Brown, Mr. William Cross, Mr. M'Naught, Mr. Rucker, Mr. Lawson, Sir Benjamin Richardson, Mr. Irving Courtenay, Mr. Knight, and Mr. Walter Hancock.

LECTURE XIX.

(Specially Contributed.)

The Mirror Galvanometer.—Before describing the instruments used with large currents, which are mostly modifications of the tangent galvanometer, it will be best to point out that in the early days of telegraphy the currents used were very small indeed, as they are in many of the experiments made in laboratory work. The instruments required for these delicate experiments are altogether different from those required in an electric light station. We in these latter days have to do with amperes; the workers in those days thought and spoke of and used milli-amperes, or less current. Some of the instruments used in laboratory work are of the astatic form, and have coils of many turns, with resistances of thousands of ohms. Even with the many coils and their cumulative action upon the needle, it would be difficult to read the needle point upon the scale with the desired accuracy; hence means were devised to increase the size of the scale divisions, and so allow of more accurate reading. In fact, the galvanometer, like any other measuring instrument, must be modified to suit the particular class of measurements for which it is to be used. Thus, for large currents we must have wires to carry such currents without fusing or heating, and coils of a few turns will probably suffice; while with very weak currents we may have very many coils of fine wire, the total resistance of such fine coils sometimes reaching to 10,000 or 12,000 ohms. It is unnecessary to dwell upon these simple things; the common-sense observations of the student informs him of them. We do not measure miles with inch tapes, nor weigh bridge girders with ounce weights. Thus, while describing a number of instruments it must be remembered these are but a few from a large number in which the principles are the same, but the details may be widely different according to the purpose for which they are intended. The mirror method of reading, which prevails in most modern instruments, was originally suggested by Poggendorff, and carried out in practice by Gauss and Weber on the Continent and Lord Kelvin (then Sir W. Thomson) in this country.

Light Rays—Incidence—Reflection.—Luminous bodies are those which are seen by the light they themselves give out. Other bodies are seen by means of the light they receive and reflect from the luminous bodies. For our purpose we may define a ray of light as a line of light. A ray of light will proceed in a straight line unless interfered with by a change of medium through which it passes. A transparent body is one that allows light rays to pass through it, while an opaque body does not allow the light rays to pass through. However, there is no body perfectly transparent or perfectly opaque. More scientifically, we might say that when a ray of light falls upon a body it is either—

1. Reflected.
2. Absorbed.
3. Transmitted.

In no case is there total absorption or transmission; there is always a portion reflected or thrown back. Any body that absorbed or transmitted the whole of the light falling upon it would be invisible, for, as I have stated, we see things by reason of the light reflected from them to our eyes. Again, if any body perfectly reflected the light falling upon it, that body would be invisible except to eyes in the path of the reflected rays. Therefore, there is no body which is a perfect reflector, for we know that the best reflectors can be seen from almost or quite all directions. This simply means that reflectors are not perfect, but the laws may be stated as if they were perfect.

A ray of light striking a reflecting surface is reflected or thrown back in a direction depending upon the angle at which it strikes. Suppose the reflecting surface to be that of a perfectly plane mirror, and suppose a series of lines be drawn perpendicular to the plane of the mirror. Let A B, Fig. 1, represent such a mirror and C D a perpendicular. Now, if a ray of light falls upon A B from D in the direction D C, it will be reflected back again along the perpendicular C D; but if the ray of light falls upon A B from some other point, I, along the line I C, it will be reflected in the direction C R, a direction in which the angle I C D is equal to the angle D C R.

The angle I C D is called the angle of *incidence*;
„ „ D C R „ „ „ „ „ *reflection*;
and the *angle of incidence is equal to the angle of reflection.*

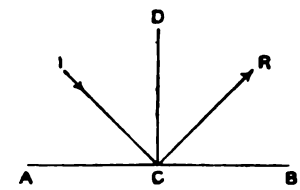

Fig. 1.

This law has proved of great use in the construction of electrical instruments. It can easily be understood that when using very small currents the weight that can be given to a needle moving under the influence of the current must also be very small, and the motion of the ends of such a small needle could not be read with any accuracy upon the scale it would be necessary to use. To overcome this difficulty, Lord Kelvin (then Sir W. Thomson) designed a galvanometer to the needle of which was fixed a very light mirror. In this instrument, as the needle moves, so the mirror moves. If then a ray of light is made to fall perpendicularly over the mirror, when the needle stands at zero it will be reflected straight back. If, however, the needle, and hence the mirror, be moved through any angle, the reflected ray will no longer be reflected along the perpendicular, but in some other direction determined by the magnitude of the angle through which the mirror moves. I have already given you the law of incidence and reflection, but with this apparatus you can see its truth clearly.

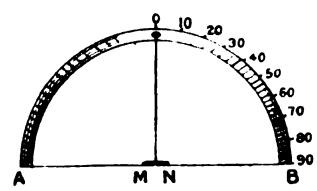

Fig. 2.

A B O (Fig. 2) is a semicircular scale. At O is a small hole through which a small beam of light passes and falls perpendicularly on to a mirror, M N. Instead of the mirror, M N, I will use this pointer (Fig. 3), to which is fixed a

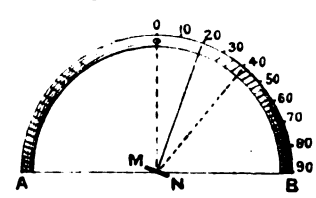

Fig. 3.

similar mirror. When used with the pointer pointing to zero, the light falls perpendicularly on to the mirror, and is reflected back to O; but when I put the pointer in any other position, the mirror it carries is moved through the angle indicated by the pointer—say, 20deg.—but you see the spot of light is reflected to the division marked 40deg.

The mirror being rigidly fixed to the position, the top of the pointer is always perpendicular to the plane of the mirror, and in the position shown the *angle of incidence* is 20deg.; but according to the law given the *angle of reflection* is also 20deg., hence the spot of light is seen on the division marked 40deg. However I move the mirror and pointer, this is always seen to be the case; hence *the angular deflection of the reflected ray is double that of the mirror which deflects it.* From this you see a second advantage in using a ray of light as pointer:

First, it has no weight.

Second, its angular motion is double that of the moving needle and attached mirror, admitting larger scale divisions, and so more accurate reading.

D'Arsonval Galvanometer.—Fig. 4 shows the principle of this instrument, in which a moving coil takes the place of the small moving magnet in other instruments. M is a strong permanent magnet, between the poles of which, to shorten the air-gap and so decrease the resistance of the permanent magnet's magnetic field, is a soft iron core, F. A light rectangular movable coil, C, is suspended above by the fine wire, W, of silver or phosphor bronze, carrying the mirror, G, and also used to conduct the current from the positive terminal to the coil. The current is conducted from the coil by a similar wire, W, terminating in the mercury-cup, A. The mercury is connected by a conductor to the negative terminal of the instrument. In the adjoining illustration the coil, C, is shown deflected for clearness sake; in the normal position it is practically at right angles to the position shown. We shall see from subsequent chapters that this instrument is similar to an electric motor, the coil or armature carrying the current revolving in the surrounding magnetic field. In

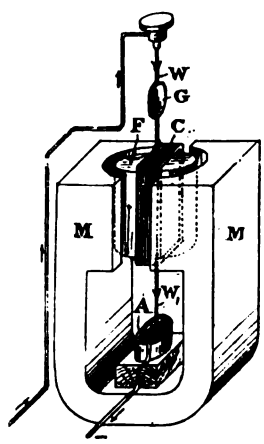

FIG 4.

this instrument the field of the permanent magnet is made very strong compared to the field of the coil, so that the turning speed of the latter is very small, and so the spot of light from the mirror on the scale moves slowly to its furthest point, and then, instead of oscillating, comes quickly to rest. Instruments of this kind, where the motion of needle or coil comes to rest quickly and without oscillations, are called *dead beat* instruments. We are in too great a hurry nowadays to want to waste time waiting for oscillations to cease, hence dead-beat instruments that come to a full stop quickly are well adapted for general use.

Holden-d'Arsonval Galvanometer.—This galvanometer, as shown complete in Fig. 5, and with its cover

FIG. 5

removed in Fig. 6, is a development of the well-known d'Arsonval dead-beat zero instrument. In the improved galvanometer we have a powerful laminated permanent magnet of circular form, and placed horizontally. The poles of this magnet are brought round to face one another, and are turned out so as to encompass the moving coil. In the centre of the magnetic field and midway between the poles, a cylindrical rod of very soft iron is placed, serving as a medium for concentrating the lines of force, and making the magnetic field quite uniform. The moving coil is built upon a light silver frame, and is wound with No. 40 silk-covered copper wire, and when mounted with its suspending wires it has a total resistance of about 16 ohms. The current is led into the coil by means of the suspended platinoid or phosphor-bronze wire, starting from a spring at the top of the instrument and passing out through another wire fixed at the bottom and attached to a mill-headed screw. The spring holding the top wire serves to give the necessary tension. The bottom screw-nut is used to produce the desired torsion to bring the mirror to the zero mark. A special point about this instrument is an arrangement for lifting out the coil and its enclosed iron core, and thereby affording a ready means of renewing the suspension wires or mirror, and making other adjustments. By simply unscrewing a clamping screw, and removing one connecting wire from a binding

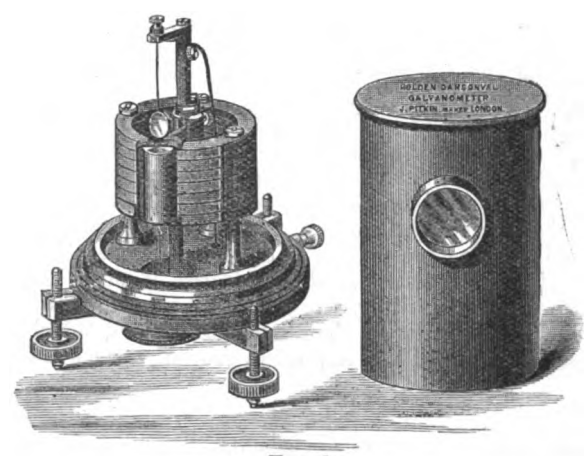

FIG. 6.

clamp, the whole coil system can be removed. The advantage of this arrangement is apparent, as a number of different resistance coils may be supplied with each instrument, and at the same time it reduces the chances of damage in transit. With a coil having a resistance of 16 ohms and an added resistance of 100,000 ohms, a deflection of the coil equal to an angle of 1deg. may be obtained with a pressure of one volt. As the scale is found to be of practically equal divisions, the instrument may be used as an ampere or voltmeter by the addition of suitable shunts or resistances.

Damping.—Dead-beat instruments are obtained by decreasing the extent of the oscillations of the magnetic needle. Naturally, there is a damping action arising from the dissipation of energy through the resistance of the air, also from the action of currents induced in neighbouring metallic circuits, and from the viscosity of the suspending fibre, etc. These, however, do not usually produce a dead-beat instrument, so that other means of damping are employed. The late C. Varley immersed the needle in a cell filled with a liquid. In older instruments, pieces of copper were put around the magnet. It can easily be seen that the resistance to motion of a liquid is greater than that of air, so that with Varley's method the needle would be sooner brought to rest. The action of the copper will be explained later on. Wiedemann makes the needle of his tangent galvanometer ring-shaped to swing in a ring-shaped cavity, but much larger than itself in the midst of a mass of copper. Lord Kelvin puts magnet and attached mirror in a flat cell, in which it can just move freely to the required extent. The damping due to the pumping of the air backwards and forwards round the edges of the mirror is so great that the needle swings off to its position of equilibrium and remains there without oscillating at all.

A Tall Chimney.—We learn from the New York *Electrical Review* that the Edison Electric Illuminating Company, of Paterson, New Jersey, have just completed a chimney 230ft. high at their works. The chimney took only about 40 days to build.

CROMPTON IMPROVED BIFILAR D'ARSONVAL GALVANOMETER.

The researches of Mr. R. E. Crompton into the advantages of the potentiometer method of measuring currents and electromotive forces naturally led to the enquiry as to what limited the accuracy of these measurements. The ruling principle being a determination of equipotential points, the sensibility of the galvanometer is a most important factor, and hence an attempt was made to break the record in this direction. The instrument of the D'Arsonval type now under consideration is certainly the most sensible of its kind to small deflecting forces. Of course, the instrument is not designed to give a proportional scale, as a deflection from zero one way or the other is all that is required. When adjusted for maximum sensibility, one-millionth of a volt will produce a centimetre deflection on a scale 200 centimetres from the instrument. This voltage is obtained by placing one-hundredth of an ohm in series with 20,000 ohms across an accumulator and attaching the galvanometer leads to the two ends of the small resistance.

This instrument is illustrated by the figures adjoining, which give some idea of the construction. The permanent magnets are of the horseshoe type, built up of four laminations which are secured to the base by the clamping-bolts. The bolts are hollowed out to receive a circular coil, A (Fig. 1), and a circular core, C, helps to reduce the resistance of the magnetic circuit. The base is made of solid brass, and the levelling screws are of a somewhat novel type. They consist of ebonite-headed screws, the ebonite being cone shaped and stepped to prevent surface leakage.

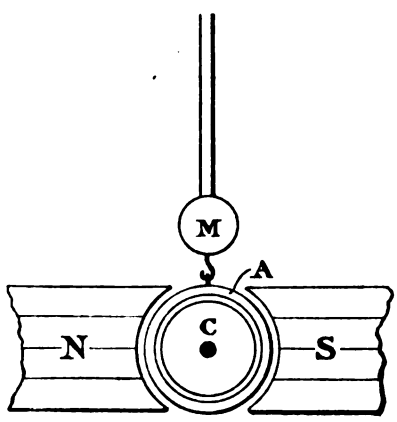

FIG. 1.—Front View of Coil and Mirror.

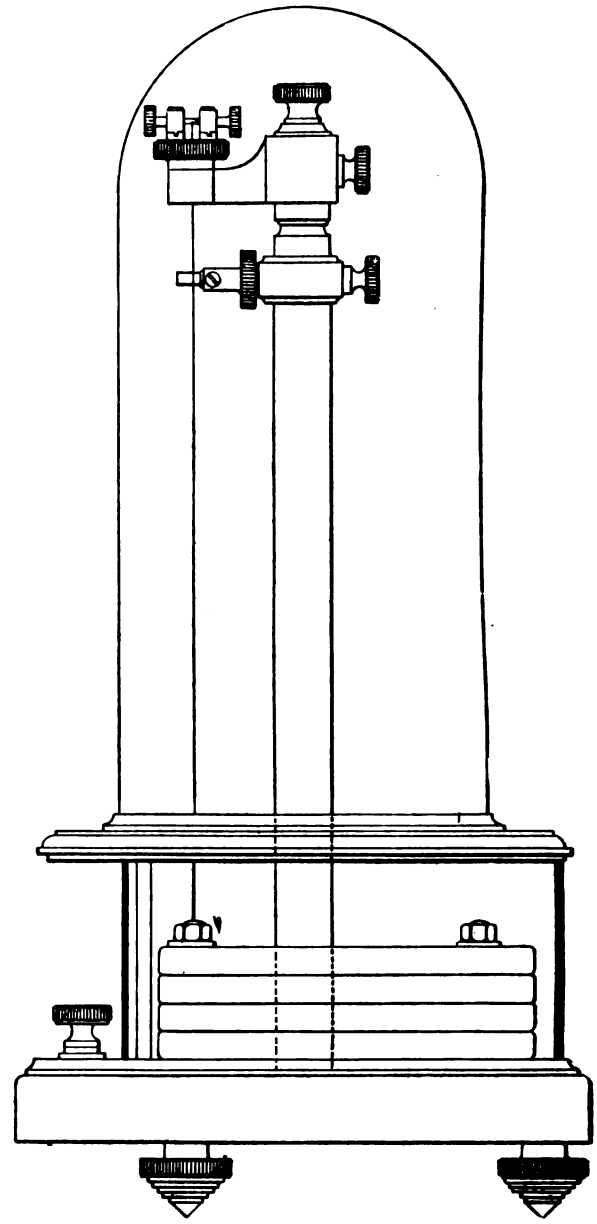
The pillar forming the support for the bifilar suspension is made of a stiff tube screwed into the centre of the brass base. The suspension is effected by means of two phosphor-bronze strips made by rolling out flat a wire of one mil diameter. The strips are attached to two pins working in conical holes of the fiddle-peg type, which are placed on the ebonite sleeve carried at the upper end of the pillar. This circular ebonite sleeve has a milled rim, and a fine slot is cut into the central hole, so that the suspension strips can be passed through it after the conical pins have been attached. The sleeve is then rotated into the correct position, which closes this slot. The projecting arm carrying the bifilar suspension is fixed to the central pillar by a long sleeve, which allows of vertical adjustment. An adjustment in the active length of the bifilar suspension is also provided by a thin strip of insulating material, which also slides on the pillar. This flat strip projects between the two suspension wires, and when parallel to them it does not touch the wires. When rotated, however, it touches them both, and thus shortens the effective length of the suspension. In this way the period of the coil and the sensibility of the galvanometer is altered (Fig. 3).

The coil is of the ring type. It is wound upon a wood former, which is subsequently removed, and is suspended by means of two metallic loops at the front and back to two hooks attached to the suspension under the mirror. The removal and fixing of a new coil of different turns or resistance is hence an easy matter. The clamping device for securing the coil for transit is attached to the core, which also is supported from the central pillar by an arm.

FIG. 2.—Elevation of Crompton's D'Arsonval Galvanometer.



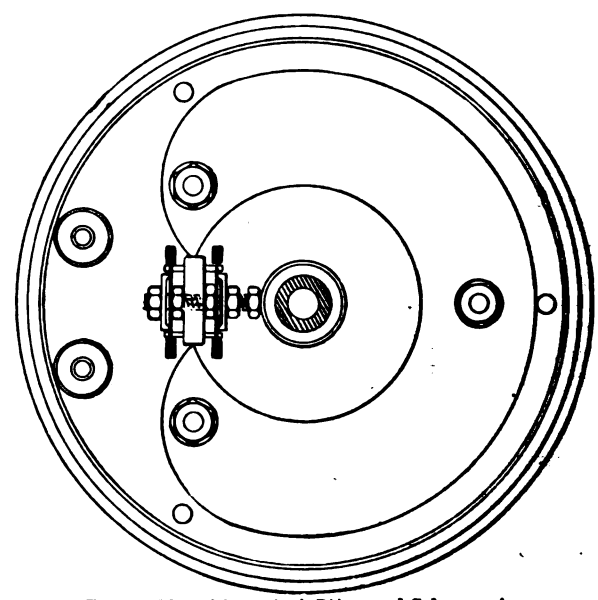


FIG. 3.—Plan of Crompton's D'Arsonval Galvanometer.

It is set in position on the arm by means of two nuts, one at back and one at front. Outside the nuts are two light springs tipped with rubber, which are kept in position by

Digitized by Google

pins in the core. They clamp or limit the movement of the coil by means of the undercut washers moved up by nuts. The washers bend the springs, and by adjusting the nut any desired limit can be given to the movement of the coil. These washers and springs can be seen in the plan (Fig. 3).

The terminals are insulated by insulating collars and discs from the base, and are connected by leads running up centre of pillar to the bifilar attachment. The whole is protected from injury by the brass guard shown, which has a portion cut away in front of the mirror. A sheet of pure plate glass is placed there in order to obtain a well-defined image. A portion even of this glass screen is in some instances cut away, and a disc of microscopic film glass, about one-hundredth of an inch thick, cemented over the opening. The whole is surmounted by a French glass shade.

The periodic time of the coil with the full length of the suspension is 6·5 seconds. The real object of the whole design is to obtain a strong magnetic field where the coil is placed, so that an extremely small current will give a deflection. This strong field, however, as shown by the careful research of Messrs. Ayrton and Mather, tends with the ordinary coil to set up a secondary effect, which prevents great sensibility being obtained.

Referring to an article on the subject in our issue of October 5, 1894, we then said: "Great difficulties were, however, found to arise when the extreme sensitiveness sometimes required in the laboratory were attempted, though a good working instrument could be made to give 100mm. deflection with a millionth of an ampere. The difficulties were chiefly due to the traces of magnetism found to exist in the silk and other parts of the coil usually considered non-magnetic, and to the fatigue of elasticity or sub-permanent set of the fine suspension required in this case. A great number of trials was made at the Central Technical College, which showed that magnetism could be detected in almost all bodies by suspending them and noting the times of vibration within and without a magnetic field. The purest wire of electrolytic copper or of fine silver, specially drawn and covered, still showed traces, and a method of treating the coils was at length devised which has practically solved this difficulty. The non-magnetic property of the new coils allow a magnet to be used whose field is four times as strong as those originally used in this type of instrument."

This phenomenon was first noticed by Mr. Mather in December, 1891, and the magnitude of its influence can be gathered from the above test on a coil of a similar type to that referred to above. The coil to be tested was suspended in the earth's field, and the period of a complete oscillation was found to be 25·2 seconds. It was then placed in a field of 1,500 C.G.S. lines per square centimetre, and the period there was only 3·5 seconds. The coil thus made more than seven times the number of oscillations in a given time corresponding to a controlling force 50 times greater than before. The action can only be accounted for by the assumption that parts of the coil became magnetic, and it can easily be seen that this secondary effect is magnified in the D'Arsonval type of galvanometer, when, with the object of gaining sensibility, the magnetic field is strengthened so that a small value may be given to the ampere-turns in the deflecting coil—in fact, the magnetic action of the coil will defeat this attempt. We understand, however, that Mr. Crompton has adopted the means devised by Messrs. Ayrton and Mather of rendering the coils practically non-magnetic.

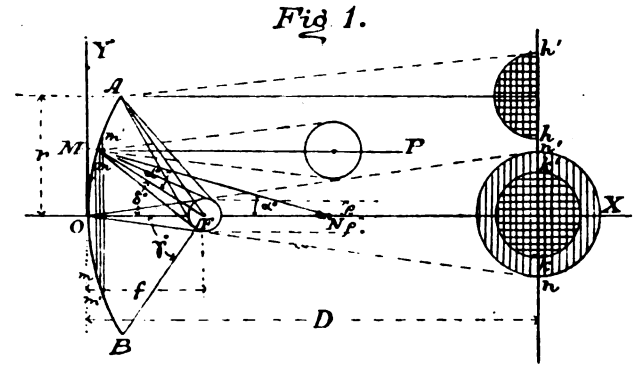
ON THE ILLUMINATION PRODUCED BY A PARABOLIC MIRROR BY MEANS OF A SPHERICAL AND OF A PLANE SOURCE OF LIGHT.

BY JEAN REY.

I. *The Source being Spherical.*—Let A O B, Fig. 1, be a parabolic mirror having its focus at F. Let M be a point on the mirror, M P the reflected ray coming from the focus, ρ the radius of a spherical luminous source placed in the focus, δ the angle made by the ray with the axis, and α the angle made by the normal either with the radius vector or with the axis. It is supposed that the luminous source follows Lambert's law, which need not be here enunciated. By virtue of this law, a luminous sphere appears to the eye as a plane disc, and a luminous spherical source is equivalent to a plane disc of the same diameter and the brilliancy of which is uniform. The luminous source under consideration has then an intensity which is constant in all directions. This intensity is equal to the surface of the plane disc multiplied by the intrinsic brilliancy—that is to say, by the brilliancy per unit of surface.

In order to facilitate these calculations, it is necessary to make an hypothesis which is perfectly legitimate—viz., that the size of the source is negligible in comparison with that of the mirror, or, in other words, the angles made by the rays leaving the edges of the source with the normal to a point on the mirror are to be considered as equivalent and equal to the angle made by the luminous ray coming from the centre of the source with the normal to the same point.

Fig. 1.



To evaluate the illumination produced in the central zone of the beam, it is necessary to calculate separately the illumination produced by each part of the mirror. If x and y be respectively the abscissa and ordinate of the point, M, the equation to the parabola when its vertex is taken as origin is $y^2 = 4fx$, f being the focal length. Let F M = l (the radius vector), and let us consider the surface of the elementary zone containing the point, M. If $m m'$ be an element ($d s$) of the parabola, then the surface of this zone is $2\pi y\, d s$. It receives light of which the intensity is "I," "I" being the constant intensity of the spherical source.

To obtain the flux of light falling upon the zone under consideration, we must multiply the intensity which it receives in the direction of the radius vector by the solid angle of this zone. This solid angle is the projection of $m m'$, in the direction of the luminous ray, divided by the square of the distance. (This from definition of a solid angle.) The value of this angle is therefore $\frac{2\pi y\, d s \cos a}{l^2}$

The flux through this solid angle is then $\frac{2\pi y\, d s \cos a}{l^2} \times \mathrm{I}$.

We must now find the illumination produced by this flux. Each of the points, M, reflects a luminous cone having as its base the image of the luminous sphere—that is to say, a plane disc of the same diameter as such a sphere. Each reflected cone has therefore a circular base. At a distance D the radius of the section of the reflected cone is $\rho \frac{D}{l}$, and the sectional area of the conical elementary beam is $\pi \frac{\rho^2 D^2}{l^2}$. Since now the elementary reflected conical beams proceeding from all points of the zone cross in space at even a moderate distance and form themselves soon into a single beam, we may consider that the zone under consideration produces at distance D a circle of illumination, which illumination is the flux received by the zone divided by the sectional area of an elementary beam calculated as above. This illumination is therefore:

$$\frac{2\pi y\, d s \cos a \,\mathrm{I}}{l^2} \div \pi \frac{\rho^2 D^2}{l^2} = \frac{2\,\mathrm{I}}{\rho^2 D^2} y\, d s \cos a.$$

As we approach the edge of the mirror, the luminous cones reflected from the elementary zones become more

Digitized by Google

acute. The elementary zone at the very edge of the mirror produces the smallest circle of illumination, $h\,h'$. It is precisely this circle which governs the dimensions of the central zone, $k\,k' = h\,h'$. As all the other zones produce larger circles of illumination which superimpose themselves on the circle, $h\,h'$, it is only this latter circle which receives light from all the zones of the mirror. On the other hand, the centre of the mirror produces a large circle of illumination, the edge of which, $n\,n'$, receives light only from the centre of the mirror itself. To obtain, then, the illumination of the central zone of the beam, it becomes necessary to find the sum of the illuminations produced by all the elementary zones of the mirror—that is, it is necessary to integrate the expression $\frac{2\,I}{\rho^2\,D^2}\,y\,d\,s\cos\alpha$ and between the limits $y=0$ and $y=r$ (the semi-diameter of the aperture of the mirror). It is clear that $d\,s\cos\alpha = d\,y$, and the illumination of the central zone becomes :

$$\frac{2\,I}{\rho^2\,D^2}\int_{y=0}^{y=r} y\,dy = \frac{2\,I}{\rho^2\,D^2}\times\frac{r^2}{2} = \frac{I}{\rho^2\,D^2}\,r^2.$$

If i be the intrinsic brilliancy of the source, then $I = \pi\rho^2\,i$, and if we call the illumination of the central zone E,

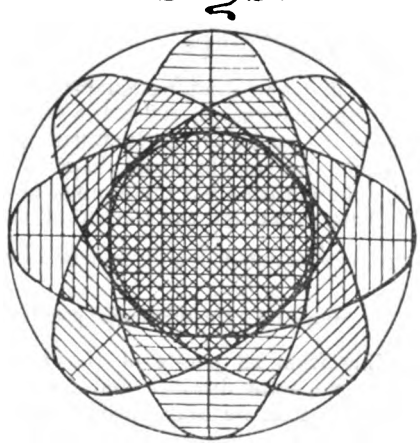
$$E = \frac{\pi\,\rho^2\,i}{\rho^2\,D^2}\times r^2 = \frac{\pi\,r^2\,i}{D^2} \text{ or } \frac{i\,S}{D^2},$$

where S is the area of the aperture of the mirror. We may say, then, that the optical power of the mirror, $E\,D^2$, is $i\,S$, or the intrinsic brilliancy of the source multiplied by the area of the aperture of the mirror. For a spherical source of given intrinsic brilliancy, the optical power of a parabolic mirror is therefore constant, and is independent of the focal length.

II. *The Source being Plane.*—If the luminous source be plane, and follow the law of Lambert, the intensity in a direction making an angle δ with the axis is $I_0\cos\delta$, where I_0 is the intensity normal to the plane source. This is exactly what happens with electric arc lamps, and be it well understood there exists no such thing in reality as a spherical luminous source.

Let us now consider a point of our parabolic mirror illuminated by a plane source. The point is illuminated by a cone of rays having the plane circular source as its base. The right section of this cone through the focus is, however, no longer a circle, but an ellipse, the major axis of which is 2ρ and the minor axis of which is $2\rho\cos\delta$. The point, M, reflects a luminous cone, the right section of which in space is a similar ellipse. Now, the dimensions of the mirror are small compared with those of the circle illuminated, at any considerable distance, and we may therefore suppose, as far as the illumination of such a circle be concerned, all points of any one zone of the mirror to be

Fig. 2



concentrated at the centre of the mirror. These points will consequently produce a series of elliptical reflected cones, the right sections of which have the same dimensions, but which are situated with regard to one another as indicated in Fig. 2. We see, then, that all the elliptical cones of which the whole beam of the zone is built up have one common part, which is a right cone having for diameter of base the minor axis of these ellipses.

Let us now calculate the illumination produced by the circular zone, $m\,m'$, $m\,m'$. Its solid angle is, as we have seen, $\frac{2\,\pi\,y\,d\,s\cos\alpha}{l^2}$. The flux received by this zone is now, however,

$$\frac{2\,\pi\,y\,d\,s\cos\alpha}{l^2}\times I_0\cos\delta = \frac{2\,\pi\,y\,d\,y\cos\delta}{l^2}\,I_0.$$

This flux, after reflection, falls upon an ellipse whose axes, at a distance D, are $2\,\rho\,\frac{D}{l}$ and $2\,\rho\cos\delta\,\frac{D}{l}$. The area of such ellipse is $\frac{\pi\,\rho^2\,D^2\cos\delta}{l^2}$. The illumination is therefore

$$\frac{2\,\pi\,y\,d\,y\cos\delta\,I_0}{l^2} \div \frac{\pi\,\rho^2\,D^2\cos\delta}{l^2} = \frac{2\,I_0\,y\,d\,y}{\rho^2\,D^2}.$$

This expression is exactly the same as that obtained in the case of the spherical source, and if we again integrate between the limits $y=0$ and $y=r$, we obtain the value

$$E = \frac{I_0}{\rho^2\,D^2}\,r^2 = \frac{\pi\,r^2\,i}{D}, \text{ or } \frac{i\,S}{D^2}.$$

Thus, in this case also, the luminous power of the mirror, $E\,D^2$, is the product of the area of its aperture multiplied by the intrinsic brilliancy of the source. In fact, whatever be the form of the source, the focal length will not enter nto the expression for the luminous power. For an ordinary lens, or for a Mangin mirror, it would be necessary to ascertain for each successive zone the exact divergence of the reflected cone ; the formulæ become very complicated, and integration becomes impossible.

The above will appear shortly in M. Blondel's new "Mémoire" on projectors ; it is rigorously exact as long as the size of the source may be considered negligible as compared with the size of the mirror. If the brilliancy of the source be not uniform all over, the value of the intrinsic brilliancy in the ultimate formula would be a mean which it would be necessary to evaluate also by the aid of the integral calculus ; but this would not change the basis of the reasoning.

THE REVISED REGULATIONS OF THE BOARD OF TRADE.

The following is the report of a committee appointed by the Board of Trade to consider whether it is desirable that the limit of low pressure as defined by the Board of Trade electric lighting regulations for the protection of public safety should be altered. The report is to be presented to the Right Hon. C. T. Ritchie, M.P., President of the Board of Trade. The committee, having duly considered the question referred to them, are of opinion—

1. That it is expedient to alter the definition of pressure in the above-mentioned regulations as follows—viz., first, omit the following words : "Pressure on any alternating-current system being taken to be the equivalent of pressure on a continuous-current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament." Secondly, in place of paragraphs (*a*) (*b*) and (*c*) substitute the following—viz, (*a*) "Where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3,000 volts whether continuous or alternating, the supply shall be deemed a high-pressure supply" ; (*b*) to be worded as existing ; (*c*) omitting "or the equivalent of 3,000 volts."

2. The committee further advise that the following amendments should be made in the proposed regulations—viz, (*a*) Regulation 1, to read as follows : "Save, as hereinafter provided, the pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals." (*b*) Regulation 31, add "No such conductor shall be at a higher pressure than 300 volts from earth." (*c*) Regulation (6) for supply omit the words, "or less than 45 volts if continuous, or the equivalents thereof respectively if alternating." In place of "150 volts" read "250 volts." Add at the end the following proviso—viz., "Provided

Digitized by Google

that no change shall be made in the pressure of the supply to any consumer in consequence of the issue of these regulations, except with his consent."

3. With reference to the suggested alteration to Regulation (31) for safety, the committee are of opinion that to enable the use of 500 volts continuous pressure between the outer conductors of a three or five wire system with bare conductors laid in conduits, the Board of Trade may give a provisional sanction to an earth connection being applied to one point of the middle conductor in any case in which they are satisfied that a high insulation is maintained on all other points of the system, and that suitable and sufficient means are provided for the immediate detection, localisation, and correction of any fault of insulation.

4. The committee consider that in making the above suggestions they have indicated clearly how, in their opinion, the question of limitation of pressure should be treated to adequately secure the safety of the public and to meet the requirements of electric lighting undertakers and the convenience of their customers.

They do not, however, wish to insist upon the exact wording suggested, and would leave the final drafting of these amendments, and any consequential verbal amendments of the draft regulations, in the hands of the Board of Trade.

(Signed) KELVIN.
" W. H. PREECE.
" P. CARDEW.

8, Richmond-terrace, Whitehall, December 2, 1895.

[Our readers, by referring to our issues of the 22nd and 29th ultimo, will find the clauses referred to and the discussion on them at the recent conference.—ED *E. E.*]

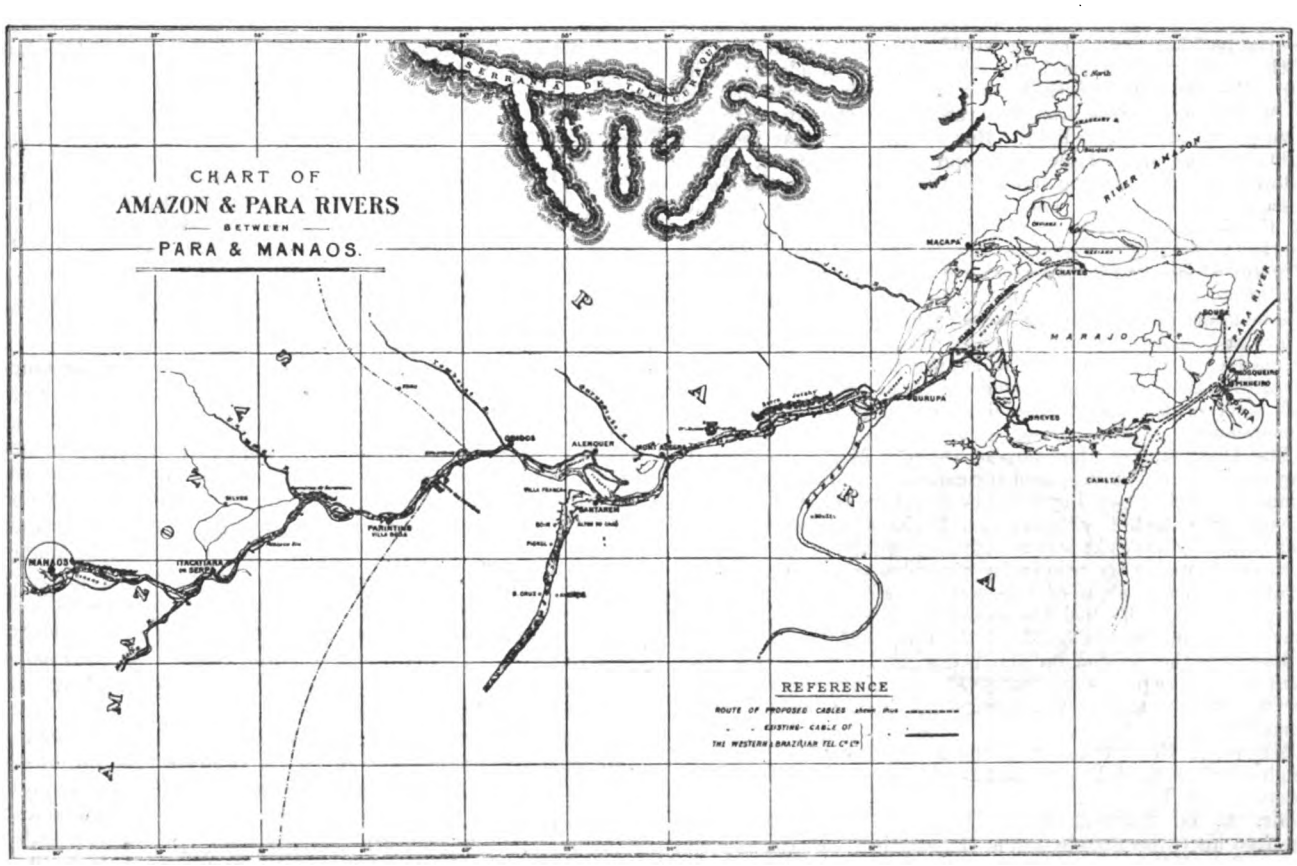
THE AMAZON CABLE.

A new and most interesting scheme for telegraphic communication in tropical countries has practically been commenced this week by the departure of the ss. "Faraday" with the city of Manaos, and also to provide communication with 14 other towns on the river. The map adjoining shows the route by which this cable is to be taken, and the branch lines connecting it to the following towns—*i.e.*, Pinheiro, Mosqueiro, Soure, Cameta, Breves, Gurupa, Chaves, Macapa, Alemquer, Monte Alegre, Santarem, and Obidos, in the State of Para, and Parintins and Itacoatiara, in the State of Amazonas.

In 1893 an attempt was made by the Brazilian Government to establish land lines between these ports, but owing to the difficulties met with in the forests and swamps bordering on the rivers, the lines had to be abandoned, after a great sum of money had been spent.

At Para the cable will join the land lines of the Brazilian Government and the Western and Brazilian Telegraph Company's cables connecting with the rest of Brazil and the Argentine Republic, and by the cables of the Brazilian Submarine Telegraph Company will be placed in communication with Europe and the telegraph system generally.

In order to avoid miscalculations, a preliminary survey was made of the proposed route, under the personal direction of Mr. Alexander Siemens, as representing the contracting firm. From the information gathered, it is stated that there should be no difficulty in placing such a cable in the river-bed, and that there were no reasons for apprehending trouble in maintenance. The great depth of the river will in most places afford protection. The fact that the "Faraday," a vessel of over 5,000 tons burden, and requiring 30ft. of water when loaded, is able to proceed up the river to Manaos, a distance of over 1,000 miles from the mouth, gives some idea of the size of the water-way. The work is being carried out by Messrs. Siemens Bros. and Co., Limited, on behalf of the Amazon Telegraph Company, Limited, which is heavily subsidised by the Brazilian Government for the next 20 years. The subsidy, however, ceases after that period, and in 30 years' time the system will revert to the Government. The contract for the construction and laying of the cables, and provision of apparatus, repairing machinery, etc., and transfer of the work to the company, was made in July last, the system being thus handed over complete and ready for work. The



Map Showing the Route of Amazon Cable.

for Para. The extremely rapid growth of vegetation in Brazil renders the maintenance of overland wires a very costly matter. A scheme was therefore devised of laying a cable in the bed of the River Amazon to connect Para specification for the work was approved by Messrs. Clark, Forde, and Taylor, the engineers and electricians to the company, under whose supervision the cables have been manufactured. The total length of the cables will be

Digitized by Google

about 1,365 miles, and by the terms of the contract they are to be completed and laid by or before March 1, 1896.

The cable is mostly of the deep-sea type, but heavily armoured ends will be spliced on where the cable is brought to the bank, and hence is liable to chafing action. The steamer "Faraday," which is owned by Messrs. Siemens Bros. and used exclusively for submarine telegraphic work, was loaded with a large portion of the cable by the end of last week. Special ventilating arrangements have been fitted up to ensure a good circulation of air throughout the vessel when in the hot climate of the Amazon district. For this purpose a large number of electrically-driven fans have been provided. The expedition will be under the personal supervision of Mr. Alexander Siemens and Mr. J. R. Brittle. A number of distinguished visitors have been invited to witness this interesting departure in telegraph practice.

SHREWSBURY ELECTRICITY WORKS.

The formal opening of the Shrewsbury electric light works—a description of which appeared in our columns last week—took place on Tuesday. A party of the principal townsmen and others, to the number of about 90, assembled as invited guests to a luncheon in the Corn Exchange given by the contractors for the plant, Messrs. Edmundsons, Limited, of Great George-street, Westminster. The Mayor presided.

In proposing "Success to the Shropshire Electric Light and Power Company, Limited," Mr. W. H. PREECE, C.B., F.R.S., in the course of his remarks mentioned that various schemes had from time to time been mooted for introducing the electric light into Shrewsbury, but nothing definite had resulted until a few influential and energetic townsmen and others, constituting the present company, took the matter up. He drew attention to the remarkable rapidity with which electric lighting was coming into favour—only in the last town where he had advised, the number of customers whom he had estimated would be connected up at the expiration of three years' working had been obtained in as many months. He was sanguine that as the light came into more extensive use the cost of production per unit would be very much less than at present—in fact, assuming that the use of electricity became general for lighting and power purposes, he calculated that the cost per unit would be as low as ½d., or equivalent to gas at 6d. It was not at all a certainty that the recent great improvements in the methods of burning gas, and the competition now going on, would not prove in the long run of the greatest assistance to the advancement of electric lighting. For had not the introduction of these improved methods of burning gas demonstrated to the public the advantages of having a beautiful clear light. But a beautiful clear and pure light, without appreciable heat, and no smoke, could only be obtained in the electric light, so that eventually the incandescent gas would, in his opinion, be entirely superseded by the incandescent electric light. He also drew attention to another fact which is sometimes overlooked—viz., the formation of water when a gas-jet is burnt, and the consequent deterioriation of perishable goods in shops owing to the condensation of this moisture on them. This was especially noticeable in cutlers' shops, and cutlers, as a rule, were amongst the first to avail themselves of the advantages which the electric light had over other illuminants. He felt confident, from the good start which had been made, that electric light would prove a success in Shrewsbury.

The CHAIRMAN of the company thanked Mr. Preece for the way in which he had proposed the company. He was rather inclined to criticise the policy of the Corporation in not undertaking the supply of electricity themselves. He instanced many towns in which the electric light was a source of profit to the corporation, and hoped that eventually the Shrewsbury Corporation would see the wisdom of purchasing the undertaking of the company, which he had no reason to doubt would prove a source of income in the hands of the Corporation and a means of lessening the burden on the ratepayers. Meanwhile, rates went up, and regrets were expressed that paying concerns like the waterworks and gasworks were not in the hands of the Corporation.

Mr. W. L. BROWNE proposed the health of "The Consulting Engineer (Mr. A. H. Preece) and Contractors of Works (Messrs. Edmundsons, Limited)."

Mr. A. H. PREECE, A.M.I.C.E., in briefly responding, declared his entire satisfaction at the way in which the whole of the work had been carried out at Shrewsbury. He was sure that the company had got a thoroughly modern and compact little installation, with first-class machinery, mains, etc.

Luncheon over, an inspection was made of the works, the current being switched on to the town circuits by the Deputy Mayor, owing to the unavoidable absence of the Mayor, after which a return was made to the Corn Exchange again, where an electrical exhibition which had been arranged was formally declared open by Mr. W. H. Preece.

THE ELECTRIC LIGHT IN SUNDERLAND.

PROPOSED EXTENSION.

The Electric Lighting Sub-Committee of the Town Council have considered a report from the electrical engineer advocating an extension of the electricity works. The scheme was adopted, the work to be carried out under the initiative of Mr. Brown.

The report submitted by Mr. Brown as to the additional plant required showed that the present plant was divided into two sets. No. 1 can supply (low-tension area) 6,000 lamps, wired, and applications have been received for 6,925 lamps. No. 2 can supply (high-tension) 1,000 lamps, wired, and applications have been received for 600. He proposed an addition to No. 1 system of two dynamos and engines to supply 7,000 lamps wired, or a total of 15,000 lamps in the low-tension area. He did not consider that an extravagant estimate of what the demand was likely to be next winter, considering that within eight months of the station being started the total output had been more than applied for, and it had been the experience of every electricity works so far established that the second year's demand was greater than the first year.

With reference to No. 2 system, he estimated for an engine and dynamo to supply 2,600 lamps wired, feeling sure that this part of the business will grow very quickly, and that many people who have their houses cleaned and repainted in the summer will, on those occasions, instal the electric light. He did not propose that this engine and dynamo should be put down at once, but should be put in the estimate so that the whole loan could be asked for. He also estimated for the approximate amount necessary for additional feeder cables in the low-tension area, as the present feeders are supplying to the extent of two-thirds of their capacity, and also an amount for meters, fuse-boxes, service cables, and small extensions that might have to be made, which should cover the extra customers put on during the ensuing year.

The amount required was £13,750, to which had to be added £2,250 overspent on the original loan due to cables in the residential district, making in all £16,000. Mr. Brown advised, in the event of the Council deciding to memorialise the Local Government Board for this loan, that they should ask that authority to allow the Corporation 30 years instead of 25 in which to repay the loan; and if the Finance Committee could borrow the money at 2¾ per cent. instead of 3 per cent. it would make the difference on 150,000 units (which is practically what this plant could supply) of one fifth of a penny per unit.

When the new plant is in working order, and if the new loan can be obtained on the above terms, the interest and sinking fund charges per unit should not be more than 2d. per unit. In Prof. Kennedy's original report the interest and sinking fund were put at 5¼ per cent., but the Corporation actually pay £5. 14s. 10d. per cent.

When the above extensions have been made, the engineer estimates the cost per Board of Trade unit as 4 20d., and the probable average price obtained per unit as 5d., leaving a profit of 8d. per Board of Trade unit, which on an output of 250,000 units is, roughly, £835. The capital expenditure to September 30, 1895, including all balances retained, is £27,241. 19s. 10d.; the present borrowing powers are equal to £25,000, so that, roughly, some £2,241 have been overspent.

In the course of his report, Mr. Brown stated: "I have further made out a statement showing the probable income and expenditure for the year ending March 31, 1896. The income and expenditure up to September 30 are from actual figures, and the balance is estimated on the results obtained to date; the units sold will certainly be reached, and possibly exceeded, it being impossible to say what will be the actual results, as a dark winter makes a great difference in the output of an electric supply station. (To emphasise this I may say that in the London Electric Supply Corporation the light winter of 1892-3 made a difference of nearly 200,000 units sold as against the previous year, which was very foggy.)

INCOME AND EXPENDITURE.

March 6, 1895, to March 31, 1896.

	£	s.	d.
Estimated expenditure	2,741	19	9
Actual income to September 30, 1895, 19,980 units	£445 4 2		
Miscellaneous revenue	36 19 0		
	482 5 2		
Estimated from October 1, 1895, to March 1, 1896, 60,000 units at 5¼d	1,312 10 0		
Miscellaneous revenue	50 0 0		
	1,844	15	3
Debit balance	897	6	7

"This statement shows a loss of, roughly, £900 on the first year's working, but it must be remembered that only 80,000 units are estimated to be sold, as against what the plant could do—viz, 100,000. If the additional 20,000 units could be obtained the loss would only amount to £450, and if Prof. Kennedy's original estimate of 5¼ per cent. as the annual charge for interest and sinking fund and also his estimated income of 6d. per unit net had been obtained, the loss would have been £75 for the first year."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STREET-LIGHTING WITH INCANDESCENT LAMPS IN SERIES.

SIR,—As street-lighting with incandescent lamps in series is comparatively unknown in England, a few words as to my experience with this system may interest some of your readers. For some two years I had charge of a municipal electric lighting station in one of the largest of our Colonial cities. Before the introduction of the electric light the streets of the borough were illuminated by 407 gas lamps. These were replaced by the same number of incandescent lamp of 25 c.p. each (of the Thomson-Houston pattern). The lamps were suspended from iron brackets attached to machine-turned poles at a height of 15ft. from the ground, and placed from 40 to 50 yards apart. They were enclosed in clear glass globes made for the purpose, but these were afterwards dispensed with, as they were constantly filling with dust and obscuring much of the light; besides this, they necessitated the employment of an extra hand to keep them clean.

At first some complaints were heard, as many of the ratepayers had expected to see arc lamps erected in place of the gas lamps, but a comparison with the gas lighting in adjoining boroughs was sufficient to convince an unprejudiced person that the electric light (even the despised incandescent lamp) was a decided improvement. Some trouble was experienced at first through having to weed out a number of high-resistance lamps, but this, of course, was not allowed to recur, all lamps used subsequently being tested at the station before they were sent out. Only once during the course of two years have I known the Thomson-Houston short-circuiting device to fail, and this was caused by an inexperienced hand having replaced the ordinary film by a piece of thick paper; but even in this instance the paper broke down after a few minutes, and the circuit was restored before the attendant reached the spot. Indeed, so sure is this device that with only ordinary precautions I would guarantee its perfect reliability. The great enemy to this device is damp, but a carefully constructed shade entirely obviates this danger. At busy corners and cross-roads the ordinary 50-c.p. gas lamps were replaced by three-light fittings. The generators employed were alternate-current machines, giving 100 amperes at 1,000 volts. Thirty-seven or 38 lamps were connected in series in each circuit, there being 11 circuits; the loss of pressure on each varying from 5 to 7½ per cent.

The life and endurance of these lamps is simply remarkable. I have known them last 5,000 hours at normal voltage and even then give a light of 12 c.p. (They were constructed to give 25 c.p. with a current of 3·5 amperes at 25 volts.) At 33 volts they would last from one to three hundred hours, giving a light of from 32 c.p. to 35 c.p. At 50 volts they would last from one to two hours, giving a light of fully 75 c.p. or 80 c.p., a slight variation in the resistance of the filament of course making a perceptible difference in the candle-power.

On the switchboard, line ammeters were connected up in each circuit; failure of a lamp in any circuit being indicated by a slightly higher reading on the ammeter connected therewith. This method is, of course, open to considerable improvement, and it would be an easy matter to make the system more perfect. In one street on the boundary of the borough, where both gas and electric lamps could be seen in direct contrast, the gas company replaced the ordinary burners by Welsbach incandescent gas lamps. This, of course, was a severe trial for the electric incandescent lamps, but the removal of one lamp from the circuit in question, and a slight increase in our working pressure, was sufficient to shame the sickly green light of the opposition.

In conclusion, I believe if this system were given an impartial trial in the hands of competent men it would rapidly find favour in many towns in England for lighting the less important thoroughfares.—Thanking you in anticipation for inserting this, yours, etc.,

HENRY J. SPENCER.

Martin's-chambers, E.C., December 9, 1895.

INSTITUTION OF ELECTRICAL ENGINEERS, Dec. 12.

The annual general meeting of the Institution of Electrical Engineers was held last evening in the hall of the Institution of Civil Engineers, Mr. R. E. Crompton in the chair.

After scrutineers had been appointed for the balloting-list, the **Secretary** read the annual report, from which it appeared that during the year the number of additions to the roll of the Institution was 216, comprising 12 foreign members, 9 members, 108 associates, and 87 students; and 38 candidates had been approved for election. The number of losses by death was larger than last year, but below the average—3 foreign members, 6 members, and 6 associates.

Mr. Crompton moved the adoption of the report, which was seconded by **Prof. Perry**, and carried.

Mr. Raworth complained that the two bodies—the Institution and the Council—were two separate entities, each pursuing their own path. He objected to the term "malcontents" being applied to those members who did not agree with the Council. Gentlemen had found the Council exceedingly difficult to approach. He moved that a special committee be formed to represent the views of the members of the Institution, such committee to consist of Messrs. A. C. Swinton, W. P. Fawcus, A. B. Holmes, A. W. Heaviside, and A. E. Mavor.

A discussion then took place as to the admissibility of this resolution at that juncture without notice; but Mr. Raworth and Prof. Perry were supported by a large number of members in their contention that the second resolution proposed was legal. A heated debate then took place, but the voting was postponed to a special general meeting. The **President**, after the usual votes of thanks to retiring officers, intimated that all the gentlemen on the ballot-list were elected.

The following are the new members also elected:

Foreign Member.—J. S. Rasmussen, Christiania, Norway.

Member.—Albert De Linde, A.M.Inst.C.E, Shanghai.

Associates.—Harry Walton Appleby, 10, Church-street, Durham; Walter Charles Bersey, Grosvenor House, Gore-road, South Hackney; Walter Binns, 128, High-street West, Sunderland; Thomas Blackburn, Barmouth, North Wales; Lionel E. Buckell, 98 and 99, Abbey-street, Dublin; James Watson Christie, 5, Electric-avenue, Brixton; Frederick Byerley Hobler, Rockhampton, Queensland, Australia; Alfred Henrick Jackson, 358, Collins-street, Melbourne; Thomas King, Invicta House, Union-street, Maidstone; Samuel George Maddison, Christchurch, New Zealand; Arthur Pettman Patey, 65, St. James's-road, West Croydon; Arthur Pearson 1, Plimsol-street, Poplar; Thomas Abraham Prout, "Goonvrea," 28, Effingham-road, St. Andrews Park, Bristol.

Students.—Arthur James Abraham, George Berry, John Patrick Clark, Charles F. Dyer. Robert Fleetwood Fuller, Nathaniel Hudson Howard, John Vincent Moinet, William Reginald Potter, Leonard Graham Stanger-Leathes, and John Gillard Stapleton, Faraday House, Charing Cross-road, W.C.; Cecil Barber, Elmfield, South Norwood Park, S.E; Reginald Charles Clinker, 89, Cliftonhill, St. John's Wood, N.W.; Arthur F. R. Curteis, Welby House, The Avenue, St. Margarets; W. E. Ferguson, 9, Brunswick-square, W.C.; Herbert Douglas Hodges, 28, Larkhall-rise, Clapham, S.W.; Sydney George Redman, 60, King's-road, Chelsea, S.W.; Charles Renton, Eastern Telegraph Company; John C. Vaughan, Wraxall, near Bristol.

WHAT, WHEN, AND WHERE.

Society of Arts.

December 16, 8 p.m.—Cantor Lectures, "Mechanical Road Carriages," by W. Worby Beaumont, M.I.C.E. Lecture III.

December 17 4.30 p.m.—Foreign and Colonial Section. "Jamaica in the Past and Present," by Frank Cundall.

Royal Meteorological Society.

December 18, 7 30 p.m.—At 25, Great George-street Westminster. Ordinary meeting. "Notes on Some of the Differences between Fogs, as related to the Weather Systems which accompany them," by Robert H. Scott, M.A., F.R.S. "Analysis of Greenwich Barometrical Observations from 1879 to 1890, with Special Reference to the Declination of the Sun and Moon," by Major H. E. Rawson, R.E., F.R Met Soc. "Meteorological Observations taken at Mojanga, Madagascar," by Stratton C. Knott, F.R.Met.Soc.

Institution of Civil Engineers.

December 17, 8 p.m.—Ordinary meeting. "The Design and Testing of Centrifugal Fans," by Hammersley Heenan, M.I.C.E., and William Gilbert, Wh.Sc., A.M.I.C.E.

North-East Coast Institution of Engineers and Shipbuilders.

December 17, 7.40 p.m.—At the Lecture-hall of the Subscription Literary Society, Fawcett street, Sunderland. Third general meeting. 1. Minutes of last general meeting. 2. Ballot for new members. 3. The discussion on W. Cross's paper on the "Surface Condensing Plant at the Newcastle and District Company's Electric Works, Forth Banks, Newcastle-on-Tyne," will be resumed. 4. The discussion on J. Denholm Young's paper on the "Application of the Law of Similarity of Marine Propellers," will be resumed. 5. Paper on "An Investigation into the Forces Tending to Produce Vibration in High-Speed Engines," by J. M. Allan. 6. Discussion.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

VOTE OR NO VOTE.

We can commend the *Journal of Gas Lighting* for again calling attention to the right of gas shareholders to vote upon electric lighting questions. Speaking solely from the standpoint of electric lighting interests, we ought perhaps to feel grateful that the great legal luminaries who have been consulted on the subject have in the majority of cases decided against the validity of gas shareholders voting. Of course, the *Journal* in its crusade against electric lighting would prefer the votes of the gas shareholders, and, strange as it may appear, we should prefer them to give their votes. It is assumed that because a man is interested in gasworks he is unable to give an independent vote at the council table. It is assumed that each gas shareholder has so great a pecuniary interest in gas that he will not jeopardise his income, or a part of it, by voting against gas. Is not this view a modern English view, and against the spirit of the nation? Do we not boast that a man is held to be innocent till he is proved guilty? Why should we assume that a man elected to serve the interests of his town should put his own interests first, and be unable to give an honest opinion? Under existing circumstances, if a number of the members of the local authority hold only one share each in the gasworks, they are interested, and held to be unable to vote upon an electric lighting question. There are black sheep everywhere, and no doubt if all votes were taken the electric light would, for the moment, be lost to some towns; but we do not believe the evil would be of long duration. At an early election the question would be made a test one, and the candidates would either have to agree to what their constituents required or give place to other men. We assume that in the majority of cases the constituents do want the electric light. We cannot assume aught else, because its superiority to all present competitors is overwhelmingly great. We cannot for one moment consent to believe that the future of electric lighting would be jeopardised by the voting of all the men on a council. Who have in many instances been the leading men to the introduction of electric lighting? In Bradford, if we mistake not, the leading spirit was the chairman of the Gas Committee. He was perhaps not interested in the same way as a gas shareholder might be interested, but we may take it for granted that he would not risk his reputation as the chairman of a prosperous town gasworks by the introduction of a competitor that would ultimately destroy the gasworks. He must have been convinced as to the superiority and inevitableness of electricity before urging his colleagues to adopt it. Look, again, at Leicester. Here we find the manager of the gasworks designing an electric light station. His interest, again, was not that of a gas shareholder, but surely his interest was to get the best return from the works in his charge, and he would not be likely to take up *con amore* an opposition works without he saw that the change must come, and preferred it in his own hands than in the hands of an outsider. Plenty of other cases might be cited where it would

Digitized by Google

at first sight be thought that the interest of the man was overwhelmingly in one direction, yet we see him earnestly advocating action in another direction.

Our view of local authorities is that the members are elected to do the best for their constituents, and that the holding of one, two, or ten shares, or a directorship, in a company is not a sufficient inducement to make the majority unfit to enquire into the merits of some scheme that will compete with the one in which they are shareholders. We imagine that the fear of rejection at the polls would be a stronger incentive to act in the direction of the wishes of their constituents than the pecuniary question would be to act against it. If the general public do not want the electric light, the difficulties in the way of its adoption will be far, far greater than if the constituents want it and a few gas shareholders don't. We do not believe there is a constituency in the United Kingdom but would, if the question of gas or electricity be properly brought before them, decide in favour of the latter, and where this is done the opposition of gas shareholders is but a small matter, and will soon be brushed aside.

CONCENTRIC WIRING.*

BY SAM. MAVOR, MEMBER.

Considering the importance of the subject of electric light wiring, it does not seem to have had an adequate share of the attention of this Institution. This is the more unfortunate as the tendency now is to allow the business of wiring to drift out of the hands of experienced electrical engineers into the hands of the legion of plumbers, gasfitters, and others who, often with small claim to the title, write "electrical engineer" upon their signboards. It is inevitable that wiring shall fall more and more into the hands of tradesmen of this class. They will follow more or less closely the methods of their predecessors, by a highly-trained and skilled tradesman. For such work as the mason's, the bricklayer's, the joiner's, cabinetmaker's, etc., a man requires the training of a long apprenticeship, which entitles him to the wages of a skilled craftsman, but the mere laying of wires already manufactured in grooved wood casings erected by a joiner, and fixing ready-made switches on bases also prepared by the joiner, do not require the serving of a long and laborious apprenticeship. On the contrary, any man who can use his hands may, with very short experience, learn to joint wires and fix switches and then call himself a wireman. The inevitable result is that such labour can, and always will, be cheaply purchased. Much wiring work is really done by irresponsible amateurs of this kind, who are ignorant of the consequences which might result from their carelessness or lack of experience.

A further reason why electric light wiring is often not carried out by first-class labour lies in the intermittent nature of the employment. There are certain seasons of the year when the wiring contractor has little of such work, and must then discharge men. Indeed, wiremen are many times taken on at the beginning of a job and paid off at the end of it. Workmen of skill and intelligence soon find this out, and they seek employment in branches of the business where their qualifications find a better and more steady market. We all know how demoralising it is for men to be idle for months at a time, and how apt they are to drift into lazy and careless habits. The accompanying diagram shows the number of 8-c.p. lamps connected to the Glasgow Corporation mains during each month from January, 1893, till the present time. The curve illustrates the fluctuations in the demand for wiring, and you will see that the wireman's load-factor is decidedly unsatisfactory.

You cannot expect a man to have a thorough interest and sense of responsibility in his work who knows that he will be paid off at the completion of the job. As wiring jobs often last only a few weeks, the poor wireman may have been in the employment of half-a-dozen masters in the course of a season, with intervals of enforced idleness. In the case of joiners and plumbers and kindred trades, when outside work is slack, the men may be employed in the shop at preparing material or in manufacturing; but not so with the wireman. The material is all already prepared for him by skilled hands—his business is only to erect it. The larger firms who have a variety of electrical work can find employment for the best of their wiremen in other branches when internal wiring is dull. But they, too, when business is brisk, have to fall back upon the shiftless creatures who often present themselves as "wiremen." The proportion of "improvers" and apprentices employed at wiring is very much larger than in any similar trade.

The business—if it may be called a business—of electric light wiring has thus several features peculiar to it making for

and defects in existing practice will thus be widely propagated. This is a question which seriously affects the whole industry, and hence the importance of this Institution setting an example by aiming at and endeavouring to secure a high standard of excellence in wiring work. It is a characteristic of the business of electric light wiring that it is peculiarly liable to the risks attending bad workmanship. Internal wiring—that is, the laying of insulated conductors in grooved wood casings, the jointing of these conductors, and the fixing of switches, fuses, etc.—is a comparatively simple matter. Apart from the distribution of lights and arranging the circuits and their routes, it is not work which must necessarily be done unreliable workmanship, which, in the absence of competent supervision and careful inspection, lead to defective work and resulting fire risk.

The plumber's and the gasfitter's work are to a great extent self-testing. If a water-pipe leaks we see the water, and if a gas-pipe leaks we usually smell the gas; but we have no sense—no physiological sense—to enable us to find hidden defects in our electric wiring. A building may be wired in the most dangerously slipshod style, yet the lamps may for years burn none the less brightly, until the latent faults have opportunity to discover themselves.

Insulation tests after the completion of the work, if in dry and well-seasoned buildings, are of little value. The insulation tests of the wiring of an old building might show results three or four times higher than the most stringent rules require, and

* Paper read before the Institution of Electrical Engineers, November 28.

Digitized by Google

yet there might be a score of dangerous defects only awaiting opportunity to develop. No tests can be applied for the detection of these defects after the work is completed and covered in. On the other hand, in a new and damp building the insulation might be far below the requirements of the rules, and yet be absolutely safe. The important thing is that the work shall be carried out in such a style that the insulation attained shall be permanent, and tend to increase, rather than decrease, with time. Wiring has to be carried out in situations so different, and must comply with conditions so varied, that it is impossible to formulate rules which can in all cases be adhered to. Modifications must be allowed to meet special requirements, and the extent of these must be left to a great extent to the discretion of the contractor. That such discretion ranges over very wide latitudes is indicated by the large discrepancies between the tenders of different contractors for the same wiring work. When the prices of experienced contractors estimating for wiring work to a carefully drawn up specification vary as we know they do, it is not strange that inexperienced contractors tendering in the absence of a specification, and without the prospect of any supervision, should quote prices which would not purchase suitable materials alone. These are matters of primary importance to the fire insurance companies, and they are much too lax in looking to their interests in this regard. Bad work is being carried out every day, and the insurance companies are complacently taking the risk. Several offices have issued wiring rules, and it is a very good thing for them to have rules; but what is the use of rules if they are not enforced? At present they are really only recommendations, and anyone who is so inclined may evade or ignore them. It is common knowledge that this is constantly done.

The present procedure of the insurance companies is most ingenuous. They send a schedule to the contractor who is carrying out the work—or, rather, who has done the work, for it generally arrives after the job is completed—and they then request the contractor to oblige them by giving replies to a list of questions. They receive the document filled up by the contractor, who has no responsibility beyond a moral one, and file it away, and presumably are satisfied that the thing is all right. They thereby exhibit a trust in human nature very flattering to the wiring contractor, but of the wisdom of which some of us may have our doubts. Until the insurance companies have organised a thorough system of inspection they will not have taken the steps necessary for their own protection. It seems to me that in every considerable town there ought to be a permanent official (in the pay of the fire offices collectively) whose duty it would be to inspect all electric light wiring while in course of erection, and to ruthlessly condemn defective workmanship or material. If such a staff of well-chosen, reliable, and sufficiently well-paid inspectors were scattered over the country, they would soon put a stop to jerry work. The moral influence of their presence in the town would be a wholesome check upon the cheap jack. The cost when spread over all the companies would be trifling, and would be amply repaid by the reduction of fire risk. The insurance companies already have one man in their collective employment in each of several of the larger cities. This man is an *attaché* of the Salvage Corps, and his duties are confined to the warehouse district. His functions are to familiarise himself with the positions of main switches, fuses, and cables, etc., in the warehouses, with a view to his being of service to the fire brigade in case of emergency.

Before leaving this subject it may be noted that Lloyd's Register of Shipping some years ago issued a set of recommendations for the guidance of shipbuilders and owners in fitting electric light on their vessels; but as they took no steps to ensure that effect was given to their suggestions these remained a dead letter. The large number of electric fires on board ship during recent years, chiefly due to inferior work resulting from the practice of accepting the lowest tender, has impressed upon Lloyd's the imperative necessity for supervision. They have, therefore, issued a new set of rules, and they are now arranging for such a system of inspection as will ensure these rules being followed. The fire insurance companies would do well to profit by the dearly-bought experience of Lloyd's. If they do not, they will assuredly have to learn the lesson at their own expense. Although the insurance companies are primarily interested in this question of fire risk, the matter has a direct and important bearing upon the electric lighting industry. We must all recognise the desirableness of ensuring that wiring shall be carried out in a style which shall be fireproof, electrically and mechanically good and durable, and shall not be offensive to the eye.

There is a steadily-growing dissatisfaction with the generally-adopted practice of enclosing the conductors in wood casings, and a steadily-growing conviction that something better might be done. In most factories and warehouses it is possible to have the casings laid upon the surface, but in dwelling-houses or in good hotels or clubs it should not be tolerated. Everyone is familiar with the unsightly wood cases and clumsy crockery ware which disfigure so many of the best hotels and other buildings in this country. How often we hear that electric light is not adopted because of the dread of the wood casings, and the cutting about and disturbance which their erection involves! Those casings are a standing reproach to the people who erect them. One has only to see the interior of a good building which a contractor has dared to wire on the prescribed lines with wood casing to realise how utterly unsatisfactory is the system. Those hideous casings are entirely out of harmony with their surroundings, and offend the eye at every turn. They blunder across ceilings and cornices, intrude upon decorative panels, and push their ruthless way through frieze and dado; while out of sight beneath the floors the joists are cut away to clear the casings until the margin of strength is often perilously low. The truth of the matter—and we all know it—is that we cannot carry out the wiring of, for example, a private residence in compliance with the recognised rules for double wiring and wood casing without excessive cutting of floors and plaster work, and disfigurement of walls and ceilings. At every turn we have to compromise between the decorations of the house and the fire insurance rules, and the concession must needs be generally in favour of the decorations. In short, the modifications of the rules require to be so many and important that this system of wood casing is one which cannot be consistently and thoroughly carried out.

When the usual double wiring is carried out in situations where moisture charged with acid from cemented or plastered walls of interiors, or in such buildings as paper-mills, wet spinning mills, dye-houses, breweries, distilleries, chemical works, and the like, the destruction of the insulation is only a matter of time, and the casing, by harbouring the moisture around the conductors, hastens the process. After the insulation has broken down, electrolysis, assisted by the acidulated moisture, takes place, and deposits away the copper of one of the conductors, with the consequent risk of heating, and ultimately of sparking. The presence of moisture being a necessary condition of the development of such faults, the dampness of the surroundings of the conductors greatly reduces the danger of fire, but that the risk is not absent is proved by the charred and burned casing or woodwork found at such places. It must be remembered, however, that heating due to diminished section of the conductor may occur at a time when the moisture which caused the fault has disappeared, and this is a danger which no amount of fuses will modify. How can you ensure that your wood-cased conductors shall never be subjected to such conditions? And how many of your average wireman's joints would stand 24 hours' immersion in water or soaking in moisture? The miserably futile expedient of attempting to waterproof the casings with putty and varnish is sometimes resorted to; such makeshifts are too childish. Lead-covered conductors are occasionally used where much moisture has to be encountered. But these for double wiring are a mistake, unless the positive and negative wires are both enclosed in the same lead sheathing. The objection to separate lead-covered conductors is that if there should be an earth or leak on the negative wire, and the lead and insulation of the positive wire becomes punctured at a damp situation, the lead becomes charged positively, and will be deposited away over its whole length where moisture is present to assist electrolysis. This remark has no application to lead-covered conductors on board ship, where the lead sheathing is throughout in intimate contact with the hull of the ship, nor to lead-covered concentric conductors. This liability to injury from moisture is the fatal weakness of the ordinary wood-cased system. It is of much greater consequence to obtain a moderately high insulation which may be relied upon to be durable, than to have—as can easily be had in a dry building—an insulation resistance of many megohms which will disappear on the approach of the charwoman and her wash-bucket, or is at the mercy of the first loose slate or leaky water-pipe. What a common experience it is to discover wiring faults in the fungus-grown casings in damp and mouldy basements, or upon the "sweating" surfaces of cemented walls or ceilings! A fault which developed a few weeks ago in the writer's office is a good illustration of the weakness of the present double-wiring practice. The walls are covered with a light-green paper, which on one side of the room is pasted to a wooden partition, and through this partition and paper the conductors are led to a switch. Behind the base of this switch sparking was observed. On examination it was found that in our humid climate the paper had absorbed moisture from the atmosphere, and this moisture, charged with an acid held in the paper, had attacked and destroyed, first the insulation of the conductors, and then the copper, until of the latter only a green sulphate remained, and the circuit was interrupted. As only one lamp was in circuit the spark was small and the heating effect slight, but under other conditions the results might have been serious. This is an interesting example of a fault developing in an apparently dry and well aired and warmed room, and under the eyes of one whose business it is to avoid such faults, and to whom a spark was the first intimation of anything being wrong.

After wood casing, with its perviousness to moisture and other

Digitized by Google

attendant disadvantages, the biggest blot on existing practice is the indiscriminate use of fuses. Some insurance people and wiring contractors, too, imagine that the risk of fire varies inversely as the number of fuses. The contrary is more near the truth. Fuses are not only a nuisance, they are apt to be a positive source of danger. The smaller number of fuses used the better; but they must be absolutely reliable, well mounted, and well placed. Most of the leading wiring contractors have adopted the distributing-box plan of wiring, in which the branch fuses are grouped at the distributing centres. This system should now be compulsory. The use of isolated fuses should be strictly prohibited. The only inducement to use them is a trifling saving in the cost of conductors. The number of fuses should be kept down by keeping up the section of conductors. The larger expenditure on branch conductors entailed is amply repaid by the simplicity and uniformity secured. The dangers of diminishing the section of conductors and scattering fuses through a building are that the crockery fuse bases and cases are liable to breakage; the terminal screws are liable to become loose, and so cause heating; and last, but most important, the danger of a conductor of too large area being used by an inexperienced or careless person instead of a *bonâ fide* fuse, in which case the "fuse" is a delusion. This last danger is so real and so imminent that the insurance companies ought long ago to have prohibited the use of such fuses. The writer was recently in competition with a firm of contractors of large experience who do a great amount of wiring, and were in this case estimating for wiring about 200 lamps of 16 c.p. each. Samples of the conductors, etc., quoted for were invited along with the estimates, and our double-wiring friends submitted a sample of each of the nine sizes of insulated cables and wires, with their corresponding wood casings, and of each of the several sizes of fuses which they proposed to use. Nine different sizes of cables and wires were certainly not essential to the double wiring of this building, but they were part of the method of a much-experienced contractor, and his method is common to many others.

Switches have been greatly improved during the last few years, both in mechanical design and in external form. The clumsy switches, with the ugliness of their porcelain covers embellished by gilt lines or floral decorations, have now nearly disappeared. They are superseded by switches of neat appearance, with suitable metal covers. The working parts of the switches are of a much more mechanical type than formerly, but there still remains ample room for improvement. There are far too many parts, too many screws, and too many contacts. The practice of dispensing with binding screws and soldering the wires directly to the contact-plates should be highly commended. How often one sees the attempt made to secure the ends of conductors—frequently of considerable size—under paltry little cheese or round headed screws and washers absurdly too light and inadequate to the purpose!

The ceiling-rose is also a weak spot in double wiring. There are far too many contacts in it. To begin with, there is the usual crockery base, and upon this base are three little brass plates, with twice that number of brass screws. Each of these six little screws binds to a contact the end of a conductor or fuse, and every screw of them is liable to become loose, and every contact to become oxidised. Where vibration or moisture are present the development of trouble is only a question of time. Do those who so freely erect these little collections of screws and contacts ever consider the harvest of petty troubles and annoyances which will be reaped by-and-by?

We must now pursue our painful path of adverse criticism to the lamp-holder. The double-contact lamp-holder, especially when attached to flexible pendants, is the frequent seat of short-circuit and minor troubles. In this little piece of apparatus there are two contact-plates, carrying the buffer springs and the inevitable binding screws. Each of these contact-plates must be insulated from the other, and both from the surrounding metal tube. When this is done, small space remains for further intrusion. But the flexible conductors are still to be brought in and pinched under the binding screws. Stray strands from these flexibles, where they are not most carefully soldered, are frequently responsible for short-circuits and the melting of many fuses. The risk would be reduced if here also binding screws were dispensed with and the wires brought straight through the insulating disc into holes in the plates and soldered therein.

It is with a sense of relief that one turns from double wiring and all its attendant ills to the simple mechanical and straightforward methods of concentric wiring with an uninsulated outer conductor. So far as the writer is aware, no system of concentric wiring in which both the inner and outer conductors are insulated has ever been used for indoor work. It appears probable that the difficulties in the way of designing junctions, switches, and other accessories which shall meet the electrical and mechanical requirements within moderate dimensions and at reasonable cost, will prevent the introduction of such a system. Two and three wire concentric cables with each conductor insulated are largely used as mains in connection with two and three wire systems, but in such cases there is no difficulty in providing junction-boxes of adequate size. The only system of concentric wiring which has been adopted for internal use has an uninsulated outer conductor, and it is this system that is known as "concentric wiring." It is important that it be clearly understood that concentric wiring is not "single wiring," but is something essentially different. This distinction between concentric wiring and single wiring is necessary, because the two have been frequently confused. No method of wiring merits the title "concentric" which is not consistently concentric throughout. In a concentric system the central conductor must be everywhere surrounded over its insulation by a metallic sheathing of conductivity equal to or greater than the core. The switches and fuses should be in the central wire and enclosed in metal cases. These cases or boxes should be electrically and mechanically jointed to the outer conductor, and so form part of the continuous metallic envelope in which the central conductor is enclosed.

It must be pointed out here that, under the existing Board of Trade regulations referring to the insulation of electric light supply mains, concentric wiring is not admissible where connection has to be made to a source of public supply in this country. This is a matter to which we shall recur, and shall meanwhile consider the question of concentric wiring with regard to installations supplied with current from independent plants. The adoption of concentric wiring is the royal road out of the difficulties and dangers which beset double wiring. It seems to be difficult for those who have been accustomed to devote so much pains to attain good insulation of both conductors to realise that there is no necessity for doing so. The adoption of concentric wiring dispenses with this necessity, and abolishes risks which make a high standard of insulation of both conductors in a two-wire system so desirable. Much misunderstanding and prejudice, due to lack of information, exist with regard to concentric wiring; but there is complete absence of valid objections to its use, and prejudice against it is soon dissolved by an acquaintance with the system.

Some of the fire insurance companies were at one time rather suspicious of concentric wiring, probably because they feared its adoption would lead to the abolishing of their cherished rules regarding the width of fillets in wood casing, etc. The insurance companies are, however, now unanimous in their favourable verdict on the subject, and have recognised the advantages of concentric wiring from their point of view. More extended experience and appreciation of its fireproof qualities must confirm the preference many of them now have for concentric wiring.

It has been stated that, owing to one conductor being already earthed, the liability to complete breakdown of the insulation is doubled. This might be true of double wiring, but is certainly not true of concentric. The outer conductor being already at earth potential, there cannot be any risk whatever of shock or spark being experienced from it. There is thus only one vulnerable conductor, and this, with its insulation being encased throughout its entire length in the metallic sheathing formed by the outer conductor, is well protected against injury. The consequences of injury to concentric and to double wiring are essentially different. In the case of the concentric conductor, if it should be crushed or a nail be driven into it, the instantaneous result is a dead short-circuit and the melting of the fuse. If the insulation should be punctured and moisture gain access, the distance across the insulation between the conductors is so small that the fault immediately develops into a short-circuit, and the spark passes from the centre conductor to the inner surface of the metallic sheathing, and being entirely within the sheathing it cannot communicate fire to its surroundings. Concentric conductors are thus self-testing. Faults cannot endure. They cut themselves out automatically. Or, rather, this is what they would do if faults were experienced, but we never have faults in lead-covered concentric conductors. How different is the case of ordinary double-wire conductors laid in the separate grooves of a wood casing! The casing which is provided for mechanical protection may become a positive source of danger, and may be ignited by leakage across the fillet—a danger which the fuse is powerless to prevent. In concentric wiring there is only one cable to handle instead of two, and this carrying its own protection the necessity for wood casing is abolished.

Perhaps the most conspicuous advantage of concentric wiring is that it may be so easily and so effectually made waterproof. The cables may be enclosed in lead sheathing laid under or over the outer conductor, and hermetically sealed to the various apparatus into which the cables are led. This must appeal to all those who have had a varied experience of wiring. If moisture—the arch enemy of good insulation—can be permanently excluded, it means the permanent maintenance of a high standard of insulation, and consequent freedom from trouble.

The next important advantage to be claimed is the large reduction in the number of fuses. The drastic method of abolishing fuses is to maintain the section of the conductors. This can readily be done in concentric wiring to an extent impracticable in double wiring. Conductors of much larger

Digitized by Google

section may be conveniently and safely led into C.C. lamp-holders, ceiling roses, and wall sockets, than is possible in double wiring. And thus, by maintaining the section of conductors right into the lamp-holders, many of the objectionable fuses are abolished. The fuses when reduced in number are more easily centralised and arranged in groups of standard size. It may be objected that if the number of fuses is diminshed a larger number of lamps are affected in the event of a fuse being melted by a short-circuit. This is a very natural objection for one experienced in double wiring to offer. But it has no application to concentric wiring. We never have short-circuits. It is in double-contact lamp-holders, and double-wire flexibles, ceiling roses, and the like, that short-circuits occur. Compare a central-contact and a double-contact lamp-holder. A 7/16 concentric cable may be led into the former more easily, and with greater safety, than two single No. 16 L.S.G. wires or their equivalent can be led into the latter. It is not necessary to lead 7/16 cables into concentric lamp-holders, but the possibility suggests the large margin of safety in favour of the C.C. holders. The difficulty of avoiding mishaps in double-wire lamp-holders will be emphasised by the introduction of 200-volt lamps. While on the subject of lamp-holders, it may be noted that, there being only one buffer spring in the C.C. lamp-holder, and that exactly in the centre, there is less risk of twisting lamps out of their collars while inserting or removing them. Concentric lamp-holders, ceiling roses, and such fittings, having only one—and that a central—contact to be insulated, may be made of better mechanical design than where within the same space two contacts have to be insulated, each from the other, and both from the containing case. The benefit of the great reduction in the number of parts can hardly be exaggerated, the liability to derangement is so very greatly reduced.

In regard to fittings, the comparison is again in favour of concentric wiring. The flexible conductors of which the pendants are made are of such large section that they are mechanically strong. The pendant terminates at either end in a screwed brass nipple with insulating plug and central contact—an arrangement which is substantial without being clumsy. No loose strands are possible. The top nipple of the pendant is screwed into the junction or fitting base, and the nipple at the lower end is screwed into the lamp-holder. The brackets are similarly wired to screwed nipples with central contacts. The erection of fittings is therefore an extremely simple operation, and the labour so employed is reduced to a minimum.

The method of concentric wiring illustrated by the patterns before you is based upon a full recognition of the fact that electric light wiring, in order to be permanently durable and reliable, must be impervious to moisture. So far as the writer is aware, this is the only method of wiring which provides a continuously waterproof metallic sheathing over the insulation from the main switchboard to the lamp-holders. The main switchboard has the usual single-pole switch and fuse arrangement, and the board is surrounded by the negative omnibus bar, which receives in sockets attached to it the outer conductors and sheathings of the concentric cables. The main cables—which are lead-sheathed throughout, and are generally armoured with galvanised iron wires laid over the lead on a cushion of jute—are carried without break or joint direct to their respective distributing-boxes, where the central conductors are soldered to the omnibus bars, and the outer conductors terminate in gunmetal sockets secured to the boxes. The distributing-boxes are of cast iron or cast brass, enamelled white inside, and fitted with fuses, or switches and fuses, as required. These boxes have close backs and hinged fronts closing upon an indiarubber ring, thus rendering them proof against dust or moisture. The concentric branch cables which radiate from these boxes are under all ordinary circumstances of uniform section—namely, 7/21½—equal in area to 0·005 square inch. The outer conductor of the cable has the same section of copper as the core, and the whole is enclosed in a solid-drawn tube of lead. Wherever a joint is to be made, or the cable led into a switch or fitting base, the centre wire is soldered to its contacts, and the outer conductor and its lead sheathing are received and terminate in a jointing pocket cast upon the switch-box or junction. The central wire and its insulation are thus enclosed throughout their length in a hermetically-sealed metallic sheathing. The section of the branch conductor 0·005 square inch is carried into every switch and into every lamp-holder, no reduction being made. There is no necessity for any fuses other than those in the cast-iron fuse-boxes, and these are all uniform and interchangeable. It is very rarely that occasion requires any departure from this plan. Many large installations have been carried out on the lines indicated, some of these amounting to several thousands of lamps, where only two sizes of fuses—main and branch, respectively uniform and interchangeable—have been used. The simplicity and reliability of such a system must be too obvious for emphasis.

The branch cables are led through buildings like flexible gas-pipes, but they are not liable to damage as composition gas-pipes are. The conductors and the insulation within the lead sheathing serve as a backing for the lead, so that it is not at all easily damaged. It has been the custom of the writer's firm for years to have their concentric conductors and joints embedded in the plaster of new buildings, and they never known a single instance of a fault developing in conductors so treated. It is sometimes objected that where the conductors are so buried they are not accessible. They certainly are not. Why should they be? It is essential that wood casings carrying ordinary double wiring should be accessible; further, it is desirable that they should be visible wherever possible. But the conditions with regard to lead-covered concentric conductors are entirely different. Given a conductor and joint of imperishable materials, and impervious to moisture and the acids found in plaster and cement, and no reason remains for laying conductors on the surface, or of providing access to them where enclosed in plaster. This demand for accessibility, and the objection to cover conductors with plaster, is a relic of the times when indiarubber-covered conductors laid in wood casing were embedded in walls. The bitter experience which rapidly follows this practice results in the prejudice against covering any conductors with plaster. If anyone wishes to have his conductors laid on the surface of plastered walls by all means let him do so, but there is no necessity either to lay them on the surface or to provide access to them where lead-covered concentric conductors are used. Access to the distributing-boxes only is necessary.

Another bogey is the chance nail driven into the plaster. Consider how largely the practice of embedding composition gas-pipes in plaster is in vogue, and how immeasurably greater is the danger resulting from the piercing of such a pipe than from piercing the insulation of a conductor! Yet how seldom one hears any objection to the practice. If a nail is driven into a concentric conductor the immediate result is an emphatic short-circuit, and the fuse melts: there is not the slightest danger. Two cases only of nails piercing embedded conductors have come under the writer's notice. Both of these were in the same building—a block wired for about 500 lights, where all the conductors were embedded in plaster. The faults—one behind a picture moulding, and the other behind a dado—were readily localised and repaired before the work was completed.

The insulation resistance of the wiring in a new building is not a matter which causes any anxiety. The lead sheathings and brass junctions and switch-boxes make one independent in this regard. In occupied buildings the lead-covered branch conductors may be led about under floors and behind plaster and linings with the greatest freedom and complete immunity from danger. The amount of lifting of flooring and disturbance to woodwork and plaster is only a fraction of that required for the carrying out of wood-cased double wiring.

The junctions employed, specimens of which are upon the table, may be manipulated by an intelligent man who can use a soldering bolt. No careful lapping of insulating material around the joint is required. The insulation is air space, and there is none better. The branch conductors being of uniform size—so are the junctions—men soon become expert in jointing. The operation is so very simple and easily performed that it may safely be done by unskilled labour. This feature specially adapts the system for export. As an illustration, it may be stated that a squad of Hindoos, chiefly tinsmiths, under the guidance of one European, carried out in the most satisfactory style the wiring for 3,000 lamps in 10 weeks.

In mills or factories floored with wood the conductors are cleated to the woodwork with brass cleats: and where iron beams and concrete floors are met, the conductors, with junctions (tapped to receive the pendants) attached at the proper intervals, are secured by brass or copper cleats to stranded steel suspending wires strained between eye-bolts attached to the walls. The laborious plugging of the concrete ceilings, with the resulting dust and disturbance to the factory and expense to the wiring contractor, is entirely abolished. In single-storey weaving sheds, ironworks, or other buildings with iron roofs divided into bays, the same method of suspending the conductors between the beams or tie-rods is adopted.

In support of the claim that this method of wiring is reliably waterproof, the case of Messrs. Nobel's Explosives Company's West Quarter Factory may be cited. The buildings to be lighted are isolated and scattered over a large area in order to reduce the risk and minimise the effect of explosions. The regulations issued by the Home Office regarding electric lighting were so very stringent that it was impracticable to comply with them except by the use of concentric wiring. With concentric wiring everything was made easy. Its waterproof and fireproof properties overcame all the difficulties. Every joint and every yard of the conductors is outside and exposed to weather, cleated for the most part to the gangways. The switches, of cast brass, and distributing-boxes, of cast iron, are also all outside, protected only by water-sheds. The work of wiring was completed more than three years ago, and, notwithstanding three years' exposure to the elements in this climate, the insulation resistance is as high as ever. Monthly

Digitized by Google

tests of the insulation are required by the Home Office, and on the 10th of last month the insulation resistance was two and a half times higher than the most stringent of the fire office rules require for indoor wiring. In the nitrating department of the same factory, which is a quarter of a mile distant from the other installation, the insulation is equally satisfactory, although the wiring is subjected to the profuse fumes of nitric acid. It is noteworthy that the insulation of the wiring at both these places is not indiarubber, but is fibrous. The exclusion of moisture is therefore solely due to the lead sheathing and waterproof nature of the joints.

The more difficult the wiring of a building appears to be, the more favourable is the comparison to concentric wiring. The iron roofs, concrete floors, moisture, and other ills that vex the spirit of the double-wirer have no terrors for his concentric friend. For wiring in any situation—from collieries to boudoirs, where difficulties of erection have to be faced, or in situations where the conductors, etc., after erection must endure excessive heat or cold, moisture, acid vapour, or inflammable dust—concentric wiring meets the case. Conviction of its immense superiority is immediately impressed by inspection of buildings so wired. The thing requires to be seen to be appreciated. Concentric wiring has this further advantage—that a very simple and easily followed set of rules can be framed which are applicable to wiring to be carried out under widely differing conditions.

Contractors who are unacquainted with concentric wiring are often ready, when they know it is in competition with their double-wire tenders, to pour into the ears of their prospective client a dismal tale of the woes which follow the adoption of any system which would not embrace their precious wood casing and crockeryware. If those contractors were informed on the subject, they would learn how great is their error. Take a contractor who has had experience of concentric wiring into any building whatever, and he will show how to make a better, more mechanical, reliable, and durable job, and generally at less cost, than is possible with double wiring. Those who have used only double wiring, and know no other, are reluctant, and with reason, to depart from practice in which their patterns are systematised and standardised, and in which their staff are trained. But when the change proposed is all in the direct on of simplicity and reduction of labour, the chief objections to its adoption are removed. That fires or minor troubles are not more frequent in badly-wired buildings is a fine testimonial to the safety of electric light wiring, but is no excuse for the continuance of slipshod work or adherence to existing methods where improvements are possible.

For mining work concentric wiring is specially adapted. The mechanical nature of the fittings and the ease with which they and the conductors may be made waterproof are important features. A concentric cable for mining purposes is more safe than two separate cables. A fall of material from the roof may rupture one of two conductors, and if current is passing the inevitable result is a spark at the point of parting. In fiery mines this might have serious consequences. With a concentric conductor, however, the fall would crush the outer conductor in upon the core, and so cause a dead short-circuit and melt the fuse before the cable parted. The spark would thus take place at the fuse at the pit bank. In the only case of such accident within the writer's experience the fuse did promptly melt. Several devices have been proposed for the purpose of preventing a spark at the point of rupture of cables used in pit work. There is room for doubt as to the likelihood of these devices performing their functions in case of need. There can be no question that the concentric cable is much more simple, and it is probably more reliable than any of them. Further, none of these arrangements afford to the miner the immunity from personal danger from shock which the concentric cable does.

An E.M.F. of 500 volts is frequently used for such work, and it is usually considered that such a pressure, although sufficient to give a disagreeable shock, is not dangerous to life. That this feeling of security is not well founded is unfortunately proved by recent fatal accidents. For power transmission in mines an ideally safe system is furnished by concentric cables with earthed sheathing, and switches, fuses, and other appliances enclosed in cast-iron cases, also earthed, and, if need be, enclosed-type motors with their casings earthed.

With regard to the wiring of ships, it is well known that an essential condition of durable wiring is that it shall be waterproof throughout. The British Admiralty for years tried all that the best materials of the usual double-wiring sort and most careful workmanship could do to secure the desired result. But the incessantly recurring faults and derangements drove them six years ago to abandon wood casing and the ordinary rubber-insulated conductors, and no longer to attempt the impossible. At the time indicated they discarded wood casing and adopted in lead sheathing of the conductors the most effectual means of rendering them permanently waterproof. It was not, however, till four years later that they fully faced the question of making the wiring systematically waterproof throughout. Cast-brass distributing fuse-boxes and cast-brass switch-boxes, all of waterproof patterns, were then adopted, and means taken to make water-tight joints between these boxes and the lead conductors.

The present patterns of distributing-boxes, etc., although they serve their purpose, are still capable of improvement, and their awkward styles admirably illustrate the difficulty of designing waterproof fittings for use in a double-wire system, where the two sides of the circuit must be insulated from each other, and both from metal of the containing boxes.

The Admiralty still adhere to double wiring, owing to fancied danger of compass disturbance from concentric wiring. In the early days of electric lighting some of her Majesty's ships were single wired, and had dynamos of unsuitable types injudiciously placed. The results were compass disturbance. (The risks of compass disturbance even from single wiring are as nothing when compared with those which may arise from the dynamos.) The navigating officers naturally became alarmed, and the alarm has not yet subsided. That well-arranged concentric wiring has no effect whatever upon the compasses of a ship has been proved by the most careful tests. The waterproof qualities of concentric wiring and the safety from fire which it ensures peculiarly adapt it for use on board ship.

The history of the development of electric light wiring in our navy is highly interesting and instructive. The conditions to be endured by wiring on board ship are admittedly severe, but it is under these circumstances that the inherent defects in a system will be most rapidly disclosed. We may profit by the experience of the Admiralty, and accept their progress as an index to the direction in which wiring practice on shore should be improved. The same defects which led to the abandonment of double wiring in wood casing in the navy exist in this system when applied to land work. The conditions on shore are less trying, and severe treatment less frequent, but the same inherent defects are there, and only await opportunity to develop.

And now with regard to possible electrolysis due to difference of potential along the outer conductor. In isolated installations where the distances are short the question of electrolysis may be dismissed as having no bearing. In cases where the distances are considerable the risk of electrolysis may be entirely avoided by adopting very simple precautions. The first of these—suggested to the writer by Mr. T. B. Murray—is to so proportion the conductivities of the inner and outer conductors that the fall in volts shall be nearly all in the inner conductor; the copper saved from the inner conductor being added to the outer in order to reduce to a minimum the difference of potential between its ends. Another method adopted by the writer is to provide between the outer conductor and its lead sheathing a very light insulation, and to earth the outer conductor only at the distant end. The layer of braiding laid for manufacturing reasons over the strands of the outer conductor before it is passed through the lead-press is sufficient for the purpose, as the maximum difference of potential between the outer conductor and the lead is only a few volts.

The risk of electrolysis is greatly over-estimated. The prejudice against earthing the return conductor is largely due to the results of the early American practice of using an earth return for street railway circuits, instead of providing an adequate return conductor. The consequence of this habit was serious damage by electrolysis to gas and water mains. But what were the conditions? In many cases the current was put to earth at the distant points at 50 volts to 100 volts above the E.M.F. of the dynamo negative, and the large currents, amounting sometimes to thousands of amperes, which had to find their way to the earth-plates at the power-house carried destruction in their path. But disappearance of these troubles has followed efficient bonding of the rails and the provision of complete metallic circuits of suitable conductivity—in other words, the substitution of a metallic earthed return for an earth return.

In dealing with distribution for electric lighting purposes we do not have to contend with such large differences of potential at different points of the system, and the difficulties are not at all comparable with those encountered in street-car work. A three wire system, with the middle earthed, and concentric wiring on each side, with the sheathings connected to the middle wire, is an ideally safe and reliable system of distribution. In a well-balanced three-wire system the fall of volts along the middle wire is negligible, and there is therefore no danger of electrolysis. No disturbance to telephones could take place. Stray currents passing between faults in the conductors would be impossible. The positive and negative conductors being each surrounded by an earthed sheathing, no current can escape from them. Leaks in concentric cables will not endure. The distance between the inner conductor and its sheathing being the only thickness of the insulation, a fault develops at once into a short-circuit which is internal to the sheathing of the cable, and the fuse at once comes into operation. But it must be repeated that faults are much less liable to occur in concentric cables than in double wiring. The importance

Digitized by Google

and safety of the self-testing properties of concentric wiring must be obvious.

As distributing networks are enlarged and extended and the number of consumers increases, it becomes cumulatively more difficult to keep up the pretence of insulation. The present supposed insulation of the three wires is a sham, and the sooner we acknowledge it the better. Experience has proved that good insulation of all three conductors in an extensive network cannot be reliably maintained. Then why not face the difficulties, and end them by earthing the middle wire?

The initiation by Mr. Sidney Baynes of the use of 200-volt lamps and 400-volt distribution on the three-wire system has a significant bearing upon this question. That his policy from the supply engineer's point of view is a sound one is beyond doubt, and that it will be largely followed in the near future is certain. But what about the interior wiring? If the attempt is to be continued to maintain the insulation of all three wires, the possibility is introduced of having a difference of potential 400 volts between one of the wires and earth. The danger from leakage across damp woodwork and the like is therefore much increased, and possible danger to life introduced.

Recent developments and experience demand the reconsideration of this question of earthing in its relation to electric light conductors. The Board of Trade have issued regulations referring to the use of uninsulated conductors for tramway and railway work. The time is ripe for the framing of regulations relating to an uninsulated middle wire in the three-wire system of distribution.

EDINBURGH.

REPORT BY THE ELECTRIC LIGHTING COMMITTEE AS TO EXTENDING THE ELECTRIC LIGHTING PLANT.

At a meeting of the Electric Lighting Committee, on a motion by Councillor Mackenzie, as to what extensions should be made to the machinery and the mains of the electric light installation, there was submitted the following report by Prof. Kennedy:

The Edinburgh electric light station, as the committee will remember, was supplied with plant sufficient for the supply of electric energy to 40 000 lamps wired. This was the number given in my preliminary report as likely to be reached within two or three years, for private consumers. I also gave, in my preliminary report an estimate of works costs as 3d. per unit (including all office expenses) when the output was 300,000 units per annum, and 2·5d. per unit when the output reached 680,000 units per annum.

To a very great extent, in consequence (if I may be allowed to say so) of the energy and determination of the convener of the committee, the number of lamps wired already, after only 7½ months' working, is equivalent to 42,300 of 8 c.p., besides arc lamps equivalent to about 3,316 more, making in all the equivalent of about 45,600 lamps of 8 c.p. already connected up, as compared with my suggested number of 40,000 after four times as long a period.

I am glad to say that not only has the success of the light been almost phenomenal in the matter of the number of consumers, but under Mr. Monkhouse's management the economy of production has also been very remarkable. The total number of units actually sold up to date has been about 285,000 (in 34 weeks), and the total station expenses, including office charges, have been about £1,850, or an average of 1·56d. per unit sold, including units for public lamps, and including carbons and lamp trimming. This result for little more than a first half year's working, including all the summer months, when the demand is a minimum, and including also the actual start, when only 2,500 lamps were connected, is quite a record, so far as I know.

It is easy now to estimate the results up to the end of the year (37 weeks from the opening of the station), and they will be approximately as follows:

Units sold, including arc lamps		384,000
Total income	£7,750	or 4·85d. per unit.
Station expenses	£2 200	1·37d. ,, ,,
Management and central expenses	575	0·36d. ,, ,,
Total working costs	£2,775	1·73d. ,, ,,
Interest and sinking fund at £7,670 per annum	5,457	3·41d. ,, ,,
Total costs	£8,232	5·14d. ,, ,,

Thus it appears that in your first 37 weeks' working you will not only have paid all working expenses, but very nearly also all charges for interest and sinking fund, in spite of the fact that the period covered has been mainly summer time. In your first completed year of working—*i.e.*, by the middle of April next—you will have sold over 800,000 units, your total income will have been about £10,000, and you will have a credit balance of between £2,000 and £3,000, after paying every charge of which I have knowledge, including interest and sinking fund at the rate mentioned above. The total working costs will have fallen to about 1½d. per unit sold, averaged since the opening of the station.

The total capital expenditure so far as it concerns matters covered by my estimates has worked out at little less than the estimates. As you are aware, however, considerable additions have been made to the work, both in the station buildings and in the mains, which have caused additional expenditure. The result seems to me to have been the best possible justification of the policy adopted by the Town Council in making these extensions. The amount taken for interest and sinking fund is the amount fixed by the town clerk, and corresponds, of course, to the actual expenditure, and not to any hypothetical amounts.

I have thought it well to place these figures fully before you, because there is no doubt that the question of extensions has at once to be faced.

From Mr. Monkhouse's statements to me, and from my own observation of what has been going on in Edinburgh, I can hardly doubt that you must be prepared to supply current to an additional 40 000 or 50 000 lamps (beyond those at present connected) by next winter; this number at least, possibly more.

In my original scheme for the station, I allowed for filling up the low-tension side with units, each of 225 kilowatts, or about 400 i.h.p., similar to the two largest which are at present in place. I have gone into this whole question *de novo*, with the benefit of Mr. Monkhouse's experience in the actual running of the plant, but have come finally to the conclusion that I cannot improve on my original plan, and should recommend that it be adhered to. Under these circumstances, the smallest addition which would meet the case would be four more machines, each of 225 kilowatts. These together would provide for 26,400 lamps alight at once, or, say, 53,000 lamps wired beyond those at present on the circuit. The station could therefore safely supply current for 90,000 to 95,000 lamps wired, including the equivalent of the arc lamps. This number will no doubt be reached by the end of 1896, and I think the only question now is whether you should put down four or six new sets at once.

This plant would, of course, provide for all required extension of arc lamps so far as they lie on the route of continuous-current mains.

On the high-tension side of the station, the addition of the 13 lamps from the post office to Regent-terrace (already sanctioned) will practically fully load the present rectifiers, leaving of course one spare machine. The proposed lamps in Clerk-street and in Leith walk will be high tension lamps, and if these are sanctioned, two more rectifiers will be required, because half the lamps must be on an all-night circuit, and the remainder on a half-night circuit. These two rectifiers will be sufficient for 25 or 30 additional lamps for still further extensions.

Four rectifiers, when fully loaded, constitute very nearly full load for one of the existing alternators, and will therefore take up all the balance of power at present available for private high-tension lighting. For this purpose an additional machine will be required, and I think it ought to be of a capacity about double that of the present ones, or, say, 160 kilowatts. It would therefore be able to supply both private and public lighting during heavy load, leaving the existing machines to come on late at night, when the private load ceases. At the same time I believe it would conduce to economical working if a motor alternator were provided which could be driven by the battery in the daytime, so as to avoid the necessity of always keeping an engine, with boiler, actually at work.

As to buildings, nothing has to be done in the engine-rooms beyond finishing the concrete foundations for the new plant, as they were fully carried out in the first instance. The boiler-house is also large enough for many more boilers than those mentioned below. But the space which must be occupied by the new boilers is used at present as coal store, and I think it would be desirable, when work is going on at any rate, to erect the gantry and finish the coal-store above the boiler-house, as I originally schemed it, and as, I believe, it is shown in Mr. Cooper's drawings.

As to boilers, at present five out of the existing six boilers are used at full load, and the output at that time is more than can readily be done by four boilers, although the five boilers are by no means fully loaded. Four boilers more would therefore be sufficient to take up double the present output, but there would be a certain constructive convenience in adding five boilers rather than four, and I should advise that, if possible, this should be done.

The present boilers and mechanical stokers have proved efficient and convenient, and I cannot suggest any improvement on the existing type except in such matters of detail as can easily be included in a revised specification.

As to mains, the existing feeders—which contain, of course, the heaviest copper—have been laid large enough for about 75 per cent. beyond their present load, so far as they are laid in armoured cable. Those portions of them which consist of bare strip, can be nearly doubled in section without moving the roadway or pavement, and at a very moderate cost. This addition ought, no doubt, to be carried out during the open weather next spring. Existing distributing mains do not require any change. The extension of either feeders or distributing mains to new districts (such as Stockbridge, Lauriston, or Dalry) is a matter to be considered and settled by the committee, but does not press just now so much as the extension of plant, as, of course, no new roadwork can be entered on until the spring.

There is another matter which I have to bring before the committee, and which is of very considerable importance. It is a

Digitized by Google

matter on which some decision should certainly be arrived at reasonably soon. I mean the question of the use of lamps of double voltage.

Two years ago, when I was asked to advise the Town Council on the matter of electric lighting, it had only just become possible to buy lamps having a voltage of as much as 115, and I advised the use of a three-wire system with this, the highest voltage then practicable. It was certain that later on lamps would be manufactured suitable for working at a much higher pressure, but how soon this would come about was only a matter of speculation. The system, however, which I recommended to you, and which you have carried out, was chosen so that full advantage could be taken of the new lamps whenever they came on the market.

They have come sooner than many of us expected, and are already to be had, of satisfactory quality, up to 200 and even 250 volts. I hope, therefore, that before long—that is, within the next two years or so—your system may be changed into a three-wire system, at just double its present voltage, a change which will quadruple the present carrying capacity of the mains, and which will involve very little change in the station plant, engines, and dynamos. (The capacity of the plant will not be increased, of course, but only that of the mains, as well as the distance to which continuous current can be supplied economically from the station by the existing mains.)

There are only two points of difficulty about the matter—viz., the Board of Trade regulations and the disposal of the existing lamps. As to the former, the matter has been referred by Sir Courtenay Boyle to a small committee (consisting of Lord Kelvin, Mr. Preece, and Major Cardew), and their decision will very shortly be made public. The question of existing lamps is a more formidable one. After much consideration I have come to the conclusion that the following plan, or something like it, should be adopted, and I hope to be able to carry it out even in Westminster, where we have about five times as many lamps to deal with as in Edinburgh. Let the undertakers give notice (*a*) that on and after a certain date (say, February 1, or perhaps May, 1896) their standard voltage will be 230 in respect to all consumers connected after that date; (*b*) that on and after another certain date (say, August 1, 1897) the new voltage will be standard over their whole system, new and old; and (*c*) that at any time between those dates the undertakers will supply any existing consumers with new lamps (for 230 volts) at the price of 6d. each, the old lamps becoming the property of the undertakers. The effect of this last clause would be that each consumer would run his existing set of lamps as long as possible, and then buy a new set very cheaply from the undertakers. The undertakers would probably lose about 8d. per lamp on the transaction. Your number of lamps, equivalent to 40,000 of 8 c.p., probably means 20,000 actual different lamps, and thus the total cost to you of an operation which quadrupled the capacity of mains which may have cost you £50,000 or £60,000 would be about £670—plus the wages of men employed in changing the lamps, etc.

There are no electrical difficulties in the way of making the change, and for your public low-tension arc lighting it would be an advantage—you would, in fact, get nine arcs worked for every eight which you now have without any additional cost. There are some difficulties in detail as to shops which at present use not more than two arcs, and as to a few motors, but these are small matters, which can easily be arranged, and it is unnecessary to encumber this report with purely technical details.

As to the cost of extensions, I stated to you in my report of April 8, 1893, that the cost of doubling the capacity of your plant and feeders would not exceed £30,000. It is quite certain now that this figure will considerably more than cover the extension named, and will leave a substantial margin for extension of mains into districts not yet provided with electrical energy.

One other matter I ought to mention—the question of the price per unit to be charged to consumers. Undoubtedly—as I have already pointed out in my early reports, and as is fully recognised by the committee—the way to make the electric light a success is to keep its price as low as possible. Although I am not to-day in a position to suggest a precise figure to you, I feel sure that you will be justified in making a substantial reduction either in the nominal price or in the scale of discounts, to take effect after the New Year. (Signed) ALEX B. W. KENNEDY.

The committee, after careful consideration of the foregoing report, beg to recommend that four engines and dynamos (low tension), one engine and dynamo (high tension), two rectifiers, five boilers, and all necessary apparatus be added to the existing plant. Should this recommendation be approved of, the committee crave a remit with powers to carry out the work.

THE RICHARDSON "I.R." ARC LAMP.

Mr. A. W. Richardson, of Patricroft, Manchester, the maker of the "I.R." arc lamp, claims to be the oldest arc lamp manufacturer in the provinces. His aim has been to design a lamp that would compete with foreign importations and at the same time attain all the necessary features essential in a first-class lamp, and with the aid of special machinery, tools, and appliances he states that he is enabled to place on the market a sound, practical small arc lamp which will enable users to obtain a good English article at a low price. Fig. 2 shows the mechanism of the lamp. The "I.R." is a differential direct-acting lamp, having a simple yet positive and sensitive feeding arrangement, which acts upon the carbon direct. This feeding arrangement is actuated by a pair of solenoids of large area, the cores of which are attached to a rocking lever which works the centre tube to which the feeding gear is fixed. This gear is fitted in a box below the lamp bottom plate, and so is protected. The whole is constructed of a metal which, it is said, will withstand the action of the atmosphere, and not corrode.

FIG. 1.

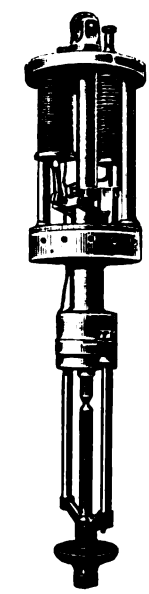

FIG. 2.

Mr. Richardson claims the following advantages for the "I.R." lamp: Cheap, sound construction, therefore durable, simple, and reliable, there being less working parts than any other; no racks, clockwork, chains, springs, pulleys, strings, make and break contacts, slide rods, flexible cords, dashpots, and no complicated delicate mechanism to get out of order; no rods to clean, as when recarboning a new carbon rod is inserted, therefore a great saving in labour. The remains of the positive carbon are used in the negative, there being, therefore, only one waste end instead of two, as in other lamps.

LEGAL INTELLIGENCE.

MITCHELL AND CO. v. MITCHELL.

The plaintiffs in this case (at the Westminster County Court on Tuesday before his Honour Judge Lumley Smith, Q.C.) are a firm of electrical engineers carrying on business in the Strand, and they sued the defendant, who resides at Grand-parade, Finchley-road, to recover a balance of account of five guineas for work done and materials supplied in connection with the installation of the electric light at the premises in question.

Mr. David Mitchell, a member of the plaintiff firm, was called, and said he had a conversation with the defendant in November last year in reference to the installation of electric light, and finally he was given an order to carry out the work. He (plaintiff) offered to give a price for the work, but the defendant said he did not want one, but wanted the work got on with at once. The order was duly carried out, and in due course an account for £15 was sent in, and various sums were subsequently paid on account, but the defendant repudiated liability for the balance, on the ground, as he contended, that there was an agreement to do the whole of the work for an inclusive price of £9. There never was any such agreement, however, either verbally or in writing, and consequently this action was brought to recover the balance.

The **Defendant** was called, and said that in consequence of a dispute which he had previously had with the plaintiffs he was particularly careful to have some distinct agreement as to the price to be paid for the work. After some conversation the plaintiff raised an objection to giving a written contract, but it was finally agreed that everything should be done for a strictly inclusive price of £9.

The jury, after a few minutes' deliberation, found a verdict for the plaintiff for the full amount claimed, and his Honour entered judgment accordingly with costs, and refused the defendant's application for time to pay.

SANDON v. THE CHELSEA ELECTRICITY SUPPLY COMPANY—FOWLER v. THE CHELSEA ELECTRICITY SUPPLY COMPANY.

These were two motions in the High Court of Justice, Chancery Division, before Mr Justice North, to restrain the defendants from carrying on their works so as to cause a nuisance to the plaintiffs. The first action was brought by the owner and some

Digitized by Google

of the tenants of flats at 21, Cadogan-gardens, which adjoins the defendants' works. The plaintiff in the second action was the tenant of one of the flats in the same house. It will be remembered that in July last an injunction was granted in each action to restrain the defendants from continuing to carry on their works in such a manner as to cause a nuisance to the plaintiffs, but the defendants were allowed until the end of October to make such alterations in their works as would abate the nuisance. There was evidence on the part of the plaintiffs that there was still "an intolerable nuisance." On the other hand, the defendants' evidence showed that very extensive alterations had been made at their works; that the steam power used on the premises had been reduced by one-half, and that certain structural alterations had been made, and were in course of being made, to reduce the vibration.

Mr. Warmington, Q.C., and Mr. Badcock appeared for the plaintiffs in the first action; Mr. Swinfen Eady, Q.C., and Mr. Rooden for the plaintiff in the second action; Mr. Moulton, Q.C., Mr. Vernon Smith, Q.C, and Lord Robert Cecil for the defendants.

Mr. Justice North, on the evidence before him, was convinced that the nuisance had been reduced, and that the defendants had made *bonâ fide* efforts to get rid of it altogether. In the result his Lordship gave the defendants a further period of three months to complete the alterations in their works which they considered would entirely remove all causes of complaint, the operation of the injunction being suspended in the meantime. But this indulgence would only be granted on the terms of the defendants paying the plaintiffs' costs of the motions as between solicitor and client.

FORGING LAMP MARKS.

At Clerkenwell Police Court, on Wednesday, Alfred Attride, of Richmond road, Kingsland; Edward Ingold, described as an electrical engineer, of Woodlands-road, Leytonstone; and George Cosgrave, described as an electrician, of Church-street, Putney, were charged on a warrant with unlawfully applying to certain lampholders marks which resemble the trade-mark of the Edison and Swan Electric Lighting Company, Limited. Mr. Wontner prosecuted on behalf of the company, and the prisoners were separately represented.

Mr. Wontner said the defendants would be charged with conspiring to defraud the Edison and Swan Electric Lighting Company, who carried on business as electricians at Queen-street, Cheapside, and with infringing the Merchandise Marks Act. It appeared that Ingold, who was the head and front of the conspiracy, was formerly in the employment of the company as a clerk. He was discharged in 1892, and since then, it would be shown, he had been carrying on a fraudulent business, with the aid of the other defendants, by means of forging the name of the company upon lampholders resembling those manufactured by the company. Attride was accused of having had a circular stamp made at the instigation of Ingold, and Cosgrave would be shown to have used a stamp belonging to Messrs. Paterson and Cooper, electrical engineers. Cosgrave had been employed by Paterson and Cooper (who were licensed by the Edison and Swan Company to stamp lamps and sell them) and he had taken the stamp home and used it. In addition to this stamp which was used in these fraudulent transactions, there was the stamp which was made for Attride by a stampcutter at St Luke's. Ingold had a number of lamps made in Germany, and when they had been stamped they were sold at less than half the price at which they were sold by the Edison and Swan Company.

Walter Findlay, electrician, formerly in the employment of the Edison and Swan Company, said he left their service in 1892. He had since then, at Ingold's request, obtained consignments of lampholders from a maker at Cologne, and Ingold paid him for acting as agent.

The case was adjourned.

COMPANIES' MEETINGS AND REPORTS.

GUILDFORD ELECTRICITY SUPPLY COMPANY, LIMITED.

The fourth annual general meeting of this Company has been held at the County and Borough Halls, Guildford.

Mr. A. F. Asher presided, and, in presenting the annual report and balance-sheet, on behalf of the directors congratulated the Company on having been successfully floated within the past two months. It was explained, for the benefit of those shareholders who had only recently taken an interest in the Company, that the Company was formed under the name of the Holloway Electricity Supply Company, Limited, in 1892 and that under that name it first applied for a provisional order of the Board of Trade for powers to supply electricity for lighting purposes at Guildford. The name of the Company was in 1894 changed to its present form. The Chairman, in mentioning these facts, referred to the way in which the Company had in its earlier stages, been opposed by the municipal authorities of Guildford, the result of such opposition being that the Company obtained a concession for 35 years under the Electric Lighting Acts, which is probably one of the longest terms ever granted to a company of this kind, and much longer than the Company could have hoped to get if its scheme had been unopposed by the Town Council. The authorised capital of the Company is £20,000, in 3,900 ordinary shares of £5 each, and 500 founders' shares of £1 each, and the shareholders appeared pleased to find not only that sufficient capital has already been subscribed to justify the directors in going to allotment, but that a contract for the works, mains, machinery, etc., has already been signed, and an excellent site for the works obtained; also that there is every probability of the current being supplied for lighting and other purposes during the next few weeks. As was remarked, however, by Mr. Kent (one of the directors), it is hoped that further subscriptions will be received at once for ordinary shares, a considerable increase in the capital being considered necessary as soon as there is a demand for current, in order to provide, amongst other things, for the cost of connecting customers' houses and shops with the mains, and for a contemplated increase in the plant. The founders' shares, on which no dividend is payable until the ordinary shareholders have received 6 per cent. per annum, have been allotted to those gentlemen who found the money to meet the preliminary expenses of the Company.

A question having been asked as to possible opposition to this Company on the part of the Guildford Gas Company, who, in their application to Parliament for increased powers now pending, are asking for power to supply electricity, it was explained by **Mr. Kent** that this application was probably only intended to obtain for the gas company power to apply their capital to electrical purposes, in case it might be advisable for them at some future time to do so, and that if these powers were obtained it would always be necessary for the gas company to apply for a provisional order of the Board of Trade, under the Electric Lighting Acts, before any competition with this Company in electric lighting could be undertaken. The Board of Trade, Mr. Kent remarked, would not grant an order giving the gas company any electric lighting powers so long as the order obtained by this Company was in force.

Messrs Asher and Colebrook, the directors retiring by rotation, were re-elected, and the meeting terminated with a vote of thanks to the chairman.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

An adjourned general meeting of this Company was held on Wednesday at the Company's Offices, Eccleston-place, S.W., for the purpose of electing an auditor. Mr. James Heslop Powell presided, and it was determined that the official auditor appointed by the Board of Trade should also act as the shareholders' auditor, in order to save the trouble and expense of two yearly audits.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brumath.—The Town Council invite tenders for lighting the town by electricity, steam power to be used. Conditions from Bürgermeister A. Bostetter, Brumath-i-Els., Germany.

Betanzos.—Tenders are invited by December 28 for the concession of the electric lighting for 25 years of the town of Betanzos, Spain. Conditions of La Direccion Gèneral de las Administraciones Locales, Madrid.

Ploesti.—The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town. Conditions from La Mairie de Ploesti, Roumania.

Chelsea.—The Guardians of St. Luke, Chelsea, invite tenders for fitting up an electrical wiring installation, with fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. For particulars see advertisement columns.

Saarbruck.—The Railway Telegraphs Inspection invite tenders by December 16 for the supply of 28 standard Morse apparatus. Conditions for one mark from Die Eisenbahn-Telegrapheninspection, Saarbrücken, Germany.

Dublin.—Messrs Arnott and Co., Limited, Dublin, invite tenders from competent firms for electric light and power installation to their new premises, Henry-street and Princes-street, Dublin. For particulars see advertisement columns.

Strasburg.—The Imperial Railway Authorities in Alsace-Lorraine invite tenders by December 17 for the supply of 1,010 telegraph poles. Conditions for 70pfg. from Das Materialien-Bureau der Reichseisenbahnen in Elsass-Lothringen, Strasburg, Germany.

Cleator Moor.—Tenders are invited for an electric light installation in the central stores of the Cleator Moor Co-operative Society. For particulars apply to Mr. J. C. Teasdale, secretary, General Office, Co-operative Society, Limited, Cleator Moor, Cumberland.

Aussig.—The communal authorities propose to have built a seven-mile single-line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig-a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Manchester.—The Markets Committee desire tenders for the supply and erection of accumulators, columns, lamps, and wiring for the lighting of the Foreign Animals Wharf, Mode Wheel. Copies of specification and drawings may be obtained at the city surveyor's office, Town Hall, Manchester, on deposit of £1. 1s. (which will be returned on receipt of a bona fide tender), and

Digitized by Google

tenders are to be sent in on the forms supplied not later than 10 a.m. on December 20.

Pernambuco.—Tenders for lighting the city of Pernambuco by electricity are invited by the Government of the State of Pernambuco (Brazil). Particulars may be had on application to the Brazilian Consulate-General, Liverpool, or to the Brazilian Consulates in London, Manchester, and Glasgow.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.—The Administration des Télégraphes require tenders by December 18 for the supply of various large lots of pine telegraph poles. Special cahier des charges No. 26 at the Brussels Bourse.

Hull.—Tenders are wanted for the supply of best South Yorkshire hard steam double-screened nuts, from January 1 to June 30, 1896, for the Electric Lighting Committee, in accordance with conditions set forth in the form of tender, which may be obtained at the electric lighting station, Dagger-lane. Tenders are to be sent to the chairman of the Electric Lighting Committee, Town Hall, by noon on 19th inst.

Mile End.—The Guardians of Mile End Old Town contemplate lighting their several establishments in Bancroft-road, Mile End-road, E., by means of the electric light, and are willing to receive from gentlemen practising as consulting electrical engineers proposals for supervising the undertaking, including preparation of all specifications and plans in connection therewith. For particulars see advertisement columns.

Transvaal.—The General Consul of the South African Republic asks tenders for the delivery of 5,000 k.g. 2 mm hard-drawn copper wire for the Government telegraphs. Tenders which are not in American Hotel, Leidsche Plein at Amsterdam, before the 20th December, 1895, will not be taken into consideration. The conditions for the delivery can be furnished on demand by Brothers Belinfante, Paveljoensgracht, The Hague, at the price of 1s.

Egremont (Cheshire).—Tenders are invited for fitting up the electric light at Seacombe, Egremont, and New Brighton Ferries, for the Wallasey Urban District Council. Specification and any further information may be obtained on application at the manager's office, Egremont Ferry, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Sealed tenders, addressed to the chairman of the Ferry Committee, and endorsed "Tender for Electric Light," must be left at the Public Offices, Egremont, by 4 p.m. on 16th inst. The contractor will be required to enter into a bond, with approved sureties, for the performance of contract. Mr. W. Danger, clerk, Public Offices, Egremont.

Leyton.—The Leyton Urban District Council invite tenders for electric lighting works as follows: Contract No. 1, central-station buildings; (3) gas-engines, travelling cranes, piping, etc.; (4) dynamos, switchboards, etc.; (5) storage batteries; (6) five miles of mains, including laying. Specifications, general conditions, and forms of tender can be obtained on and after Monday, December 9, at the offices of Prof. Henry Robinson, C.E., 13, Victoria-street, Westminster, on payment of 5s. for each specification, etc., and tenders on printed forms, in separate envelopes, and accompanied by a £10 Bank of England note (which will be returned, unless the tender is withdrawn before the contract is signed), are to be sent to Mr. R Vincent, clerk to the Council, Town Hall, Leyton, Essex, on or before six o'clock on Tuesday, December 17.

Durban (Natal).—The Corporation desire tenders for the supply, for delivery at Durban, and fixing at Durban, of steam and electrical plant for the lighting of the borough by electricity. The work will be executed under the direction of Mr. Fletcher (borough engineer) and Mr. Hadfield (electrical engineer) at Durban. The plant required includes high-speed engines, dynamos, cables, arc and other lamps, accumulators, etc. Specifications and plans can be obtained from Mr. W. H. Radford, C.E., Angel-row, Nottingham, consulting engineer to the Corporation, on deposit of £5. 5s., which will be returned on receipt of a bona fide tender. Sealed and endorsed tenders, in duplicate, must be delivered at the offices of Messrs. Webster, Steel, and Co., agents to the Durban Corporation, 5, East India-avenue, Leadenhall-street, London, E.C., by 28th inst.

RESULTS OF TENDERS.

Bristol.—The Docks Committee have accepted the tender of Mr. Lewis for the erection of a telephone call-room at Avonmouth Dock for the National Telephone Company.

Belfast.—The Electric Committee have accepted the tenders of Messrs. J. H. Holmes and Co. and Messrs. Gill and Russell for instruments and malleable iron pipes respectively.

Ossett.—The Low Laithes Coal Company, Limited, of Gawthorpe, Ossett, R S.O., having determined to adopt electricity for their new hauling plant, the necessary order has been placed with Messrs. A. Hirst and Son, electrical engineers, of Crescent Works, Dewsbury. The plant will be capable of giving out 55 h.p.

Stafford.—The Town Council have accepted, on the recommendation of the Gas and Electricity Committee, the tender of the Stanton Ironworks Company, Limited, amounting to £65. 12s. 6d., for the steam-main to be laid from the electric station boiler-house to the gasworks boiler-house, and that of the Smethwick Boiler Covering Company, amounting to £38, for covering such steam-main with non-conducting material.

Sheffield.—The Town Council have accepted the tender of the Sheffield Electric Light and Power Company, Limited, for supplying and fixing the electric installation for the Town Hall for the sum of £720 (Sunbeam light) or £743 (Edison-Swan light), for whichever system may be recommended by the Consultation Sub-Committee; also the tender of Messrs. W. Singer and Sons, of Frome, for supplying and fixing the electroliers at the Town Hall for the sum of £1,028.

Bedford.—The Electric Light Committee of the Town Council have accepted the tender of Messrs. Robert Stevenson and Co., Limited, of Newcastle-upon-Tyne, at £467, for the supply of a centrifugal pump and engine, also surface condenser with air-pump and engine. In connection with this contract Alderman Richards said he thought it right to say, on behalf of the committee, to save any misunderstandings in the future as there were in the other contracts, that this was not the lowest tender.

BUSINESS NOTES.

Swansea.—The tenders for the Swansea electric lighting scheme have been received, and will be considered at the meeting of the Electric Lighting Committee.

Harrogate.—The town clerk has reported that an enquiry is to be held by Mr. W. J. B. Clerke, M.I.C.E., into the borrowing of £27,000 for purposes of electric lighting.

Berlin.—The construction of the projected electric circular railway between Berlin and the southern suburbs is now definitely assured, the Berlin Magistracy having granted the necessary license.

Kidderminster.—The plans of the proposed electric tramway have been deposited with the town clerk, and the borough surveyor has been instructed to examine and report upon them to the Town Council

Chelmsford.—At a meeting of the Relief Committee in connection with the fire at Messrs. Crompton and Co.'s, it was reported that nearly all the men were in employment again, only 30 remaining still out.

The Telegraph in Brazil.—On November 7 was published the decree opening a credit of 200,000dol. for an extension of the State telegraph line in Maranhao to the town of Palma, in the State of Goyaz.

Queenstown.—The Town Commissioners have passed the application to the Board of Trade for a provisional order to provide the town with electric light. The price of gas in Queenstown is at present 4s. 9d. per 1,000ft.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended December 8 amounted to £1,042, as compared with £855 in the corresponding week of last year, being an increase of £187.

Leeds.—The Tramways Committee have not yet received the report of Dr Hopkinson on the proposed experiment to be made in electrical traction in Leeds, and meanwhile do not intend to go further into the tramway haulage question.

Connobbio (Italy).—It appears probable that the electric light installation will be in operation on January 1. There are already numerous applications, and only the approval of the superior authorities is awaited in order to begin work.

Fleetwood.—The report of the Highways and Markets Committee will recommend the Town Council not to accept the proposals of Messrs. Bennett and Druce, electrical engineers, Preston, for the transfer of the Fleetwood Electric Lighting Order, 1890.

Milan.—The work of installing the electric light in the Church of St. Ambrogio is about to be begun. The church will be entirely lighted by incandescent lamps, except only the altars, where, for reasons of ritual, only wax candles or oil is allowable for lighting purposes.

Hammersmith (London).—The Vestry have decided to engage the services of an expert at a cost not exceeding 200 guineas to advise them on the question of electric light and to make a complete report on the schemes and tenders for the lighting of the compulsory area.

Bowness-on-Windermere.—A member of the District Council has asked why the electric lamps were lighted the previous Sunday evening, when it was just about full moon? As he was a pretty large ratepayer he considered it a proper question. The Surveyor said they were not lighted to his knowledge.

Bangor (N. Wales).—A sub-committee, composed of Dr. Langford Jones, Dr. Grey Edwards, Messrs. R. Davies and H. Lewis, have been appointed by the City Council to prepare evidence for submission to the inspector of the Local Government Board upon the enquiry as to the loan for electric light.

Woking Electric Supply Company, Limited.—This Company has been registered with a capital of £20,000 in £1 shares. Objects: to enter into an agreement with A. G. New and A. J. Mayne, and to carry on the business of an electric lighting company in the parish of Woking and neighbourhood.

City and South London Railway.—The returns for the week ended December 8 were £977, compared with £941 for the corresponding period of 1894, being an increase of £36. The total receipts for the half-year 1895 were £20,527, compared with £20,518 for the corresponding period of 1894, being an increase of £9.

Dudley.—The Streets and Gas Committee of the Town Council have reported that the deputation appointed by the committee had waited upon the Dudley Gaslight Company, and that the directors stated that they could not under present circumstances reduce the price of gas. A member said that it was admitted that the Dudley gas was poor.

Digitized by Google

Newport (Staffs.).—The Urban District Council have received a letter from Mr. Heane, secretary to the Newport Gaslight and Coke Company, offering the concern of the company to the Council for £10,000, but the Council declined the offer. Councillor Smith said if the electric light paid in a town with gas at 2s. 3d. per thousand, it must pay in Newport with gas at 4s. 6d.

Windsor Electrical Installation Company, Limited.—This Company has been registered with a capital of £10,000 in £1 shares. Object: to acquire the undertaking of the Windsor Electrical Installation Company, and to carry on the businesses of electrical engineers, electricians, etc., in all their respective branches. Registered office: Albany House, Frances-road, Windsor.

Ipswich.—Messrs. Fraser, who supply two arc lamps to the Corporation for street-lighting from their private installation, have asked to be relieved from their contract so far as business hours are concerned, and the Corporation have agreed to this subject to Messrs. Fraser paying for additional gas lamps required to take the place of the arc lamps. The latter will still be run after the shop closes.

Electric and General Investment Company, Limited.—The directors have declared an interim dividend on the capital paid up on the ordinary shares of the Company at the rate of 10 per cent. per annum for the six months ended November 30 last, the dividend to be payable on and after the 23rd inst. The transfer-books and register of members will be closed from Monday to December 23 inclusive.

Belfast.—At the meeting of the Electric Committee considerable discussion took place about the gas-engines not giving entire satisfaction, but no report was submitted. Mr. M'Cowen, the engineer, stated that orders for illuminating shops and business establishments had come in almost up to the full extent of their lighting power, and a short extension of main to Messrs. Kirker, Sons, and Co.'s premises was ordered.

Copper.—A Michigan newspaper is responsible for the assurance that the Calumet and Hecla Copper Mine, which recently increased its output to a large extent, will revert to the old rate of production at the beginning of the year. The company is represented as having "no desire to flood the market with copper, or to increase the production to an extent that would threaten the maintenance of a price not below 11 cents per pound."

Huddersfield.—The Town Council have passed the formal resolution for an application for a provisional order to supply electric energy to the Longwood district, but the decision as to the "omnibus" Bill, which, among other matters, covers the tramway question, was postponed. At the town's meeting held to consider this Bill there was great opposition to some of the provisions, and a poll of the town has been asked for.

Electric Tramways in Scandinavia.—A company has been formed in Bergen, Norway, for the purpose of building an electric tramline, the capital of some £50,000 being to a great extent German, and, naturally, a German firm will be entrusted with the contract. In Gothenburg, Sweden, an electric tramway is under contemplation, proceeding from the station of the Bergslagernes Railway through the most populous parts of the town.

Aberystwyth.—Councillor Harries, at the last meeting of the Town Council, had on the agenda the following motion: "That the Public Lights Committee be required to consider and report on the desirability and probable cost of lighting the Meat and General Market, the town clock, and the Old Assembly Rooms by means of the electric light, and that an arc lamp be placed at a point to be selected at or near the Angel Inn." The motion was carried.

Clerkenwell (London).—The County of London and Brush Electric Lighting Company have given notice to the Vestry that on the following week they would be prepared to switch in several of the leading thoroughfares of the parish. Mr. Putterill asked if all the transformer-chambers were properly drained? Mr. Walton thought not. He knew of one case where there was no connection between the transformer-chamber and the gully. The surveyor was requested to see to this.

Yeadon (Yorks.).—The Urban District Council have decided to appoint Mr. Page, assistant to Mr. Medhurst, electrical engineer, in conjunction with Mr. Wilson, the Council's collector, to make a canvass of the township and ascertain the number of electric lights which would be taken up by the inhabitants. The information is needed for an adjourned ratepayers' meeting, to be heid on the 23rd inst., for the purpose of determining whether or no the electric lighting scheme shall be proceeded with.

Aylesbury.—A special meeting of the Urban District Council has been held for the purpose of considering the desirability of applying to the Board of Trade for a license as defined by the Electric Lighting Act, 1882, to supply electricity under the said Act for public and private purposes within the area of the urban sanitary district of Aylesbury, and to decide if such application should be made. After some little discussion it was unanimously resolved that nothing should be done in the matter.

Appointment Vacant.—There is required, for the Devon County Asylum, Exminster, a competent fitter to take charge of the machinery, including pumping, heating, and electric lighting. Applicants must be capable of executing all ordinary repairs. Wages, £2. 2s. a week and cottage. Applications, in writing, stating past experience, and accompanied by not more than three testimonials, to be sent to Mr. Arthur E Ward, 9, Bedford-circus, Exeter, clerk to the Visiting Committee, by 16th inst.

Colwyn Bay (N. Wales).—On the proposal that the District Council should oppose in the next Parliament the Colwyn Bay and District Dissolution and Reincorporation of Colwyn Bay and District Gas and Lighting Company Bill, as it was in contravention of the Council's Electric Light Company, etc., Bill, and against the interest of the ratepayers of the district, which had been adjourned from last meeting, coming up for discussion, a heated debate took place, and ultimately the resolution was lost.

Bath.—A recommendation from the Technical Education Committee of the Town Council, and confirmed by the Municipal Buildings Committee, that gas be laid on to the new schools, was questioned by Mr. Hallett, who alluded to the sanitary advantages of electric light, and pointed out that it had been placed in the Municipal Buildings, where it was not so necessary. Alderman Sturges took a similar view. Alderman Bright said they had the question of lighting under consideration. The report was then adopted.

Eastern Extension Telegraph Company, Limited.—An interim dividend has been declared for the quarter ended September 30 last of 2s. 6d. per share, free of income-tax, payable on the 15th prox. The share register will be closed from the 7th to the 14th prox., both days inclusive. The coupons of the Company's 5 per cent. Australian Government subsidy debentures due January 1 next will be paid on and after that date, at Messrs. Barclay, Bevan, and Co.'s bank, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

The Tariff for International Telegrams.—Signor Ferraris, the Italian Minister of Posts and Telegraphs, with a view to reducing the tariff for international telegrams, has, says *Elettricità* of December 8, proposed to the States constituting the Postal Union that an international tariff should be adopted equal to the sum of the inland charges of the States through which the telegram has to pass. Thus a telegram dispatched from Rome to London would pay a rate obtained by adding together the charges for an inland telegram in Italy, France, and England.

Ayr.—The Town Council have remitted to the Electric Lighting Sub-Committee a motion, "That a committee be appointed to consider the advisability of adopting tramways between Ayr and outlying districts, to be driven by oil, electric, or steam motive power, or cable or horses, and with power to enquire as to same and report." It was agreed to get a telephone connection to the electric light works. The clerk was instructed, on the suggestion of Mr. Hammond, to write to Messrs. Siemens and Messrs. Fowler urging them to push on with their contracts.

North Shields.—Mr. A. A. C. Swinton has at present in hand an electric power-transmission plant of considerable size for Smith's Dock Company, North Shields. The plant will be used for pumping out the water on a large new pontoon dock, and will consist of two sets of Belliss engines and Crompton dynamos, giving together 570 e.h.p., supplying eight 60-h.p. electromotors of Messrs. Scott and Mountain's manufacture, each coupled direct to an 18in. Gwynne centrifugal pump. This is probably the first instance in which electricity has been applied to the raising of a floating dock.

Brandon and Byshottles (Durham).—The Urban District Council have received a letter from the Local Government Board referring to the proposal to light Brandon and Byshottles by electricity, and pointing out that they would not before entertaining an application for sanction to a loan require the Urban District Council to obtain a provisional order, but that if a license were obtained the Board would limit the period for the repayment of any loan which they might sanction to the period for which the license was granted. Such period could not exceed seven years.

Sheffield.—On the formal resolution for the Corporation Tramways Bill, giving power to take over and work the existing tramways of the city, coming before the Council, opposition was raised by Alderman Carter and others, but eventually, when a division was taken, it was found that there were 48 votes for going forward with the Corporation Bill, four against, and five neuter. Afterwards formal resolutions were carried to oppose the Bills of the Sheffield Tramways Company, the Sheffield District and Rotherham Tramways, and the Sheffield District Railway; and a retainer was given the town clerk to conduct the Bill of the Corporation and the opposition to the outside Bills.

Wells (Somerset).—The report presented by the Electric Lighting Committee to the Town Council recommended that the preparations for the installation of the electric light be proceeded with, and asked that the committee might be empowered to select a site for the electric light works. The report was adopted by the Council. Subsequently, however, Mr. G. W. Wheeler moved that the whole question of electric lighting be left in abeyance for one week, and that the town clerk be instructed to offer the sum of £14,000 for the gas company's works. This was seconded, and, after much discussion, carried by the casting vote of the Mayor. The gas company ask £19,680.

South Staffordshire Tramways.—The town clerk of Walsall has received a letter from the secretary to the Electric Construction Company, Limited, stating that they had given notice to the South Staffordshire Tramway Company that they could not continue to run the electric portion of the latter company's lines on the present terms beyond the end of the month, when the existing arrangement would terminate. The reason given for this notice was that the road bed of the line was in a bad condition. The Town Clerk said the letter was of such importance to the town that it had been brought before the Council at the earliest possible moment, and on the suggestion of the Mayor the matter was referred to the Streets Committee.

The Rumoured Resignation of Sir William van Horne, which is announced from Montreal, would a year or two ago, the London *Chronicle* says, have been an even more momentous Canadian public event than the retirement of the Premier of the Dominion.

Digitized by Google

Those were the days when, as the saying went, the Canadian Pacific Railway Company ruled Canada and Van Horne ruled the Canadian Pacific. Sir William van Horne started life as a 13-year-old telegraph operator on the Illinois Central Railway, and mounted by stages till he became general manager and vice president of the Chicago, Milwaukee, and St. Paul Railway. That was in 1880, in which year Canada began in earnest her stupendous task of carrying an inter-provincial railway from Atlantic to Pacific.

Bury St. Edmunds.—The Mayor (Mr. Oliver), the borough surveyor, and two members of the Electric Lighting Committee having visited the Bedford electric lighting works and made enquiries, have reported that they were informed that although when the works were started it was not absolutely certain there would be a customer, the works were now being carried on at a profit. As was stated in our last issue, Mr. Medhurst, electrical engineer, has been instructed to prepare a scheme for lighting the borough by electricity, but it was understood the committee did not bind themselves to any particular scheme, or even to carry out any scheme of electric lighting at all There are private installations in the town for shop-lighting, and these are reported to be giving great satisfaction.

Aberdeen.—The electric light has just been introduced into the handsome offices of the Northern Assurance Company, 1, Union-terrace. There are about 100 lamps distributed throughout the building. In the counting house are three elegant electroliers, the lamps being covered with artistic vine-shaped shades. There are five lamps in the manager's room, five in the board-room, three in the secretary's office, three in the telephone-room; and the safes and strong-rooms, situated on the basement flat, are all efficiently lighted. The offices of Messrs. Adam, Thomson, and Ross, and Messrs. Wilsone and Duffus, advocates, who are tenants in the building, are also lighted by electricity. The lamps used are of 16 c p. and 32 c p. The installation was fitted up by Messrs. Shirras, Laing, and Co., of Aberdeen.

The "Radiant" Incandescent Lamp.—This improved incandescent electric lamp is made by Messrs. Rose and Bird, Limited, of 120 and 121, Newgate-street London, E C., at their works in Westminster, under the personal supervision of the director of the works. The filament, manufactured by a new process, is said to be of remarkable hardness, strength and uniformity, rendering the life of the lamp very much longer for the same initial efficiency, and the candle-power is claimed to be maintained to a much greater degree than in any other lamp on the market, and the amount of current consumed much smaller—most important considerations to users of electric light. The company undertake the manufacture of any special lamp required, and careful attention is given to all requirements as to voltage, candle-power, and efficiency.

Halstead (Essex).—The clerk to the District Council has been directed to reply to the gas company's letter as to the price of gas that the Council were not satisfied with the company's terms, which they regarded as simply giving a discount for cash. The Council would not be satisfied if they did not have a reduction of 5d. per 1,000ft. Mr. Adams asked if the Council adopted electric lighting in place of gas whether private customers would be supplied? Several Councillors: Yes. Mr. Adams: Well, then, I should think we can get our light at a much cheaper rate. I'll move that the electric light question be seriously considered by the committee with a view to substituting electric light for gas. The Chairman: I think the committee are considering it. Mr. Carter: Yes, sir; but they would be strengthened by such a resolution. Mr. Clark seconded the resolution, which was agreed to.

Ripon.—The Mayor has moved the adoption of the minutes of the Gasworks Committee, of which he is chairman. These included an application by Messrs. G. Harrison and Co., electricians, of Ure Bank Engine Works, for permission to cross Minster-road with overhead wires for the purpose of lighting the cathedral by electricity. The town clerk laid before the gas company the position of the Council as the lighting authority of the city, and the committee resolved to recommend the Dean and Chapter to allow Messrs. Harrison and Co. to place the generating works on the south side of the cathedral, so that the experiment of lighting the cathedral might be carried out entirely within the premises of the Dean and Chapter, and avoid crossing the street. The town clerk was also instructed to obtain information as to the cost of a license from the Board of Trade to sanction the Corporation supplying electricity within the city

Blackpool—The minutes of the Electric Lighting and Tramways Committee, as submitted to the last meeting of the Town Council, contained the following: "Alderman Bickerstaffe was appointed chairman. The borough electrical engineer is to submit a scheme for any necessary extension of the electric lighting plant. The letter from the Blackpool Tradesmen's Association as to additional light in business streets was referred to the Street Lighting Committee. The letter from Messrs. Finch and Johnson, as to alleged nuisance from the electricity works, was referred to the town clerk and borough electrical engineer. Two new tramway cars to be purchased after first submitting tenders. The letter from Mr B Sykes, as to the proposed tramway from Blackpool to Fleetwood, was referred to the Parliamentary Sub Committee. The tramway traffic manager is to submit a scheme for contract passes." After discussion, the minutes were passed.

Derby.—In the Town Council Mr. Hart rose to make a personal explanation. He said that he had been criticised for stating to his constituents that a great amount of unnecessary money had been spent on the electric light station, and that the ratepayers had not had full value for their money. He went through a large number of figures in support of that statement, and called the attention of the Council to cases where sums of money had been paid for extras not included in the contracts, and, in conclusion, said that he was stronger than ever of the opinion that a large amount had been spent needlessly, and that results equally as good might have been obtained by far less expenditure. Alderman Leech said that he was quite prepared to show Mr. Hart that in regard to the figures he had quoted he was under a misapprehension, and that all his arguments could be answered to the satisfaction of the Corporation. The Mayor hoped Mr. Leech would defer his reply to a future meeting of the Council, and the matter then dropped.

Pitlochry (N.B.).—About four years ago Prof Forbes, son of the late Principal Forbes, of St. Andrew's, whose family has had a connection with Pitlochry for the last 40 years, devised a scheme for lighting Pitlochry by electricity, the motive power to be derived from the Falls of Tummel. At that time no further steps could be taken, as the proprietor of Faskally, being under age, could give no title to the water. Mr. A E. Butter, of Faskally, has, however, now agreed to have details of the proposal worked out, with the view of ascertaining whether the electric light could be supplied at a reasonable cost. Prof. Forbes (of Niagara fame) has, it is stated, been communicated with, and it is expected that a definite scheme will shortly be arranged The gas supply has at times lately proved inadequate, and the company were meditating an extension of their works, but should electricity be introduced this will be unnecessary. It is thought that the gas company might take up both systems, thus preventing rivalry, and securing economy in the management.

Stapleton (Glos.).—The committee appointed by the Urban District Council to enquire into the possibility of the Council adopting electricity as the public illuminant for the district, have presented a preliminary report. They were not yet prepared with a report on the financial aspect of the question, but were of opinion that the cost of providing the power for lighting such a large district would be prohibitive, especially from one station, and that unless some natural available power could be secured, as an auxiliary to steam power, it would be necessary to erect extra stations to light separately such detached districts as Eastville, Stapleton, Ashley-down, and Fishponds. The committee further reported that they understood that the Great Western Light and Power Company were making an application to the Board of Trade for a provisional order empowering them to supply electric light and power in the district, and that it should be opposed. The Chairman then proposed that the Council oppose the application. This was carried unanimously.

Glasgow.—The Corporation tramway sub-committee on mechanical motors have reported that after consideration of the question they were of opinion that some form of mechanical motor should be tried on one of the tramway routes, provided the committee, on enquiry, were satisfied that such motor would be more efficient and economical than the present mode of haulage. With that object they recommended that an exhaustive enquiry should be made as to the various motors in actual work under conditions similar to those of the route proposed to be experimented on, and that the remit to them should be extended accordingly, with power to call in such technical assistance as they might consider necessary. Mr. Walter Paton moved the approval of the minute. Bailie M'Cutcheon seconded. Treasurer Gray took exception to the proposal. They had only just begun to run the tramways at a cost of £400,000 by means of horse haulage. They should pay off some of the debt before they commenced this exhaustive enquiry. But the minute was ultimately approved.

Brighton.—The *Sussex Daily News* says: "While the extension of electric lighting in the main inland thoroughfares in Brighton is warmly welcomed, there is one matter in connection therewith which is not received with unanimous approval—the erection of the lamp standards in the centre of such busy traffic centres as the bottom of West-street and the New-road entrance to North street. The objection comes from drivers of vehicles. One gentleman, whose patronage is extended to the town throughout the whole of the winter season, condemns the standard as unnecessary and dangerous. There is certainly a good deal to be said for the contention that the spots mentioned could be just as well illuminated if the pavements were made the site of the erections." At a complimentary dinner to Councillor T. H. Richards, Councillor Stafford, referring to what had been said as to the lighting of certain squares in that district, mentioned that a scheme was on foot for the better lighting of side streets by incandescent electricity, and by utilising the existing gas standards. The electricity undertaking generally had, he said, been a source of great profit to the ratepayers, and had helped to bring about a reduction in the rates.

Worcester.—Alderman Airey called attention at the last City Council meeting to the accounts for coal for the work of the Electricity Committee, amounting to £461, and said the whole accounts submitted by that committee amounted to £952. 5s. 3d. He understood that when the electricity works were placed at Powick the object was to dispense with steam power, and that they would have water power sufficient for all requirements. Alderman Williamson (chairman of the Electricity Committee) remarked that the Council could not have been under the impression indicated by Alderman Airey, or they would not have laid down steam plant at a cost of £7,000 or £8,000. As to the amount of coal consumed, the season had been abnormally dry, it having been one of the driest they had had for 20 years, and they had suffered very much from that. But even if they had had an average flow of water, they would have had to use a considerable quantity of coal. The amount of coal used was, he thought, exaggerated by some members, for the total cost of the coal used at the works to the end of September was £638. 4s. 8d., including

Digitized by Google

haulage, and this he did not think was at all a large amount, considering the work done and the dryness of the season.

Hampton Wick (Middlesex).—The Lighting Committee of the District Council have reported as follows: "The Lighting Committee, aided by the surveyor, have consulted the authorities of Kingston on the question of electric lighting for Hampton Wick. They found that the Corporation are unable to quote a price for public lamps, as the cost would greatly depend on the number of houses which would take a supply of electricity. To ascertain this, the Corporation ask to be allowed to send a circular to the inhabitants of this district. The committee recommend that this be agreed to. The gas company undertake to substitute incandescent gas lights for the present lamps at a capital charge of 10s. 9d. per lamp, without increased yearly charge, where the present lanterns are not too worn out for the change In any case, electric lighting could not be had under two years. Its cost would considerably exceed that of the incandescent lights, and the parish would be committed to it for at least 25 years. Under the circumstances your committee recommend that the village, from the bottom of Church-grove to the railway station, be lit with the incandescent light," etc. Ultimately the matter was postponed.

Bucklow (Cheshire).—Mr. Fawcus and Mr. Fairlie have appeared before the Rural District Council on behalf of the Altrincham Electric Supply, Limited, in connection with their request for the consent of the Council to the application of the Board of Trade for a provisional order to extend the area of supply within the Council's district. A difficulty has arisen from time to time owing to complaints that the company had not left the footpaths in a satisfactory condition. This being the case, the Council desired some assurance from Mr. Fawcus as to the future. Mr. Fawcus agreed to repay to the Council the expense they had incurred in placing the footpaths in proper condition, and to pay any further charges they might be put to in making the footpaths in a satisfactory condition. Also for the future, not only as regarded the new, but the old area, on behalf of his company, he agreed to a scale of charges for the maintenance of roads and pavements broken up by the company, after they had been filled up. He further consented, on behalf of the company, to an agreement being entered into similar to the last one, as to the purchase by the Bucklow and other authorities. After fully discussing the matter, the Council gave their consent to the application to the Board of Trade.

Weybridge.—Mr Bilney has submitted to the Urban Council a report of the committee appointed to confer with the chairman and another representative of the Weybridge Electric Supply Company. He also said he had received a letter to the effect that the company was prepared to transfer the provisional order to the Council on payment of the nominal sum of £100 before December 15. He thought, however, the Council ought to get an assurance from the Board of Trade—in the event of their purchasing the order—that the order would be vested in them to the exclusion of any contractors who wished to light the place The Chairman remarked that the order would probably be revoked soon, and he suggested that the Council might be able to get the order without the payment of the £100 Mr. Bilney said the committee had put that matter before the representatives of the company, but they refuse to entertain it; in fact, he was rather surprised to have seen the concessions contained in the letter to him Dr. Powell said that as the present committee had done their work so well, he proposed they should continue the negotiations with the company. Messrs. Bilney, Chambers, and Dix were then reappointed to again confer with the representatives of the company on the subject.

Electric Traction in India.—The last number of the *Indian Engineer* reports that trial trips were being made by Mr. Gadsby, the electrical engineer of the Madras Tramway Company, on portions of the new sections of the line to be worked by the overhead system. The wire which is to supply the current for these sections has been taken underground from the power station along Whannels-road over St. Andrew's Bridge along the Coum and across to Swami Naick's-street, Chintadripet, where it joins the line and is then carried overhead on posts. The cars to be run on this line are similar to those now running, except that they will be lighted by electricity from the overhead wire. Portions of the line were fit for working at once, but it was considered unsafe to work without lightning arresters, which were shortly expected. The same journal discusses the question of tramway traction for Calcutta. It says: "The solution of the problem of a suitable mode of traction for tramways in Calcutta hinges itself on the accommodation which its streets will provide. Electricity has been tried in Madras, and after the conduit system had been abandoned for the overhead or trolley system the latter, having proved fairly successful, finds many advocates. But we are decidedly of opinion that electrical traction, as now understood, is wholly unsuited to Calcutta."

Burslem.—The committee of the Town Council have reported that they had considered the proposed agreement with the North Staffordshire Tramways Company, at a meeting at which Mr. Sellon, electrical engineer, and Mr. Garcke attended, as a deputation on behalf of the company, and explained their views with respect to the clauses relating to the power of the Corporation to purchase the undertaking within the borough at the end of 22 years, on paying to the company a sum equal to the cost of the structural equipment less a deduction of 5 per cent. for depreciation, in addition to the value of the permanent way and rails. They also gave a positive assurance that the tramway extensions to Goldenhill, Smallthorne, and Longport would be carried out by the company within two years. The committee recommended that the agreement be approved of, subject to clauses being inserted binding the tramway company to make and work these extensions, and they further recommended that a clause be added to the agreement that the company should also make and work an extension to Wolstanton. After some discussion it was resolved to refer the purchase clause back to the General Purposes Committee for further consideration, after another interview with Mr. Sellon, with power to close the matter, and with this exception the report was adopted.

Barnet (Herts.).—The report of the Electric Lighting Committee has been considered by the Urban District Council. Nine meetings had, the report stated, been held since May last, with the view of gaining information as to the annual cost of public lighting by electricity as compared with the existing method of lighting; the systems to be adopted for public and private lighting respectively; the efficiency of the light after installation; and the best available method of introducing the light, having regard to initial outlay. As a result of interviews with representatives from the firm of Messrs. Vaughan and Brown, electrical engineers, of Kirby-street, Farringdon-road, and correspondence with the same firm, the committee found that a satisfactory installation would involve an initial outlay of about £8,000. Owing to its compactness Barnet was eminently suitable for the electric light, but the ultimate financial success of the undertaking would depend upon the number of private consumers. Messrs. Vaughan and Brown had been asked to provide the capital upon the provisional order being assigned to them, but they were not willing to take that responsibility. The committee, in view of other approaching liabilities connected with the extension of the district, felt that it could not advise the Council to at present undertake a scheme of electric lighting. Moreover, the committee felt that it would be inadvisable for the Council to lose the provisional order. The report was adopted.

Neston and Parkgate (Cheshire).—Mr. F. Pocklington, of the firm of Messrs. Callender, who have done electric lighting in Liverpool, and are engaged in it in Birkenhead, attended the last meeting of the Urban District Council. Mr. Grenfell said Mr. Haigh had introduced Mr Pocklington to him, and the latter had voluntarily offered to answer any questions in reference to electric lighting. Mr. Pocklington was closely questioned by Mr. Pemberton as to the numerous points included in Mr. Marsh's scheme and as to the general details in connection with electric lighting. Other members also questioned Mr. Pocklington, and the latter, having been thanked by the Council, afterwards withdrew. Mr. Pemberton said he was sceptical as to whether the scheme proposed could be carried out for the figures named, but he was open to conviction. Several of the most influential ratepayers in the district had spoken to him on the matter, and had pointed out that the Council were placing the sub-committee in an undignified position by causing them to ask for private subscriptions to prosecute their enquiries. A motion in favour of enquiring further into the practicability of lighting the district at a reasonable cost had been passed by a large majority at a public meeting and it was only fair that the public should pay for the enquiry they had asked for. He therefore moved that the sub-committee be empowered to spend the sum of 20 guineas in obtaining the necessary reports. This was carried unanimously.

Cardiff.—The *Western Mail* says: "A small but influential syndicate has been formed at Cardiff for the purpose of working two patents, one of which is for making metallic insulators, and the other for an improved method of making an insulated tubing for electric wiring purposes. The patentees (Messrs. Alfred J. P. Whitaker and F G. Treharne) have secured very suitable premises on the East Moors, Cardiff, adjoining the works of the Cardiff Tin-stamping and Enamel Company, Limited, and they are now being fitted up with the necessary plant, so that work can be commenced not later than January 1 next. The subscribers to the syndicate are: Her Grace the Duchess of Marlborough, Lord William Beresford, V.C., Sir William Thomas Lewis, Mr. Edward Davies, J.P. Alderman Mathias, J.P. (Porth), Mr. J. W. Palmer, Mr. Alfred J P. Whitaker, Mr. F. Gwilym Treharne (analytical chemist), Mr. G. C Downing, Mr. E J. Hancock, Mr. J. E. Gunn, and Dr. M. H Greener. The first directors of the syndicate will be Lord William Beresford, V.C. (chairman), Mr. Edward Davies, J P, Alderman W. H. Mathias, J.P., Mr. Alfred J. P. Whitaker, and Mr F. G Treharne. The solicitors are Messrs. Downing and Handcock, London and Cardiff Very few enterprises in Cardiff have been started under more favourable auspices. One of our representatives on Wednesday visited the site of the new industry, and found the machinery and preparations generally so well advanced that there is every reason to hope everything will be in readiness to start on January 1 next. The most searching tests have been successfully applied, and the patents, it is believed, will effect a revolution in the process of insulation."

Edinburgh.—The Lighting Committee of the Edinburgh Town Council have remitted to a sub committee proposals for the lighting by electricity of the following thoroughfares: from Leith to Pilrig, southward to Salisbury-place, Fountainbridge, from Regent-terrace to Abbeyhill, along Lauriston to Tolcross, and Dalry-road. Lord Kingsburgh has read a communication at a meeting of the Royal Scottish Society of Arts, in the course of which he remarked that as regarded the use of electricity they could have no more striking example of the development that had taken place than their own city of Edinburgh at the present moment. It was an interesting fact that in Edinburgh Prof Kennedy, the skilled adviser of the Corporation, had laid his plans upon the footing that provision for 40,000 lamps would be amply sufficient for the next three years, and still at the end of 15 months—and when

Digitized by Google

they had only had an actual supply of light for six or seven months—the whole number of lamps was already taken up, and the Corporation were engaged in a frantic effort to make the plant sufficient for all demands that might be made upon it. Several gentlemen offered observations on the communication. One of them was Councillor Mackenzie, who, as convener of the Electric Lighting Committee of the Corporation, said that they hoped to present a report to the Town Council promising to reduce the price of the light to consumers from 6d. to 5d. a unit, to abolish meter rents, and further to reduce the price charged to the city for street lighting. Even then the committee trusted to have a handsome balance. The only danger they anticipated at present was that people would use the light in an extravagant and careless manner. Taking everything into account, he contended that the electric light, even at 6d. a unit, was cheaper than gas.

Llanelly.—The Property and Estate Committee of the Borough Council recommended the Council to agree to transfer their electric lighting order to Messrs. Howell upon the following terms: "Mr. Howell to pay £200 for the order. All costs of transfer to be paid by the purchaser. Option of purchase by Council at the end of five years, and subsequent periods of seven years, upon the following terms: goodwill for the first five years £1,500, afterwards three years' previous profits; going plant to be taken at a valuation, such going plant to include land, mains, and cost of laying down same, buildings and machinery, public lamps (if any erected) at cost of company. If the Council purchase within the first five years, they have to repay Messrs. J. C. Howell £150 in respect of the order. After that period the said £150 to be subject to proportionable yearly reductions, Council not to pay anything in respect of promotion of expenses upon the retransfer to them. Council not to give their consent to any other company during the agreement with Messrs. J. C. Howell." Mr. John Griffiths thought that the Board ought not to part with the order for less than what it cost them to obtain—£280 Mr. Guest said that one of the conditions ought to be that the Council would not give consent to any other company coming into the town, unless Messrs. Howell refused to do any work which the Council thought was required. Suppose for instance, the New Dock district required to be lighted with electricity in 10 years' time, and Messrs. Howell were not prepared to do it. Then the Council should have the power to call in another company to carry out the work. He believed that that was intended as one of the conditions by the committee Mr. Brodie thought that a proviso should be added to the conditions with regard to the buildings, etc., that they should be such as to be properly available for the purpose After some further discussion, the additions suggested were incorporated in the minutes, and in that form were unanimously approved.

Tunbridge Wells.—The Lighting Committee of the Town Council have decided that Mr. H Preece should superintend the carrying out of the extension of the central station at a remuneration of 2½ per cent on the additional £12 000 The contractors for the dynamos agreed to at once place in hand a new machine to replace one of the present ones, and would then modify the other till the efficiency was raised, and they trusted the third machine would be used for the extensions This was agreed to, on the understanding that the committee were under no responsibility to purchase the third machine, and that they held the contractors liable for any loss by the machinery not being up to the specified efficiency. The telephone company wrote calling attention to the disturbance of their system at Tunbridge Wells, and suggested that the engineers of the Corporation and the company should confer with a view to ascertaining whether the cause of the disturbance could be easily and speedily removed. The matter was referred to Mr. Preece, who had an interview subsequently, and wrote that he hoped to be able to report at the next meeting. An order for 100 meters was given. The resident engineer reported that Sir David Salomons had agreed to pay all the expenses of the opening of the electric light station, and the thanks of the committee were voted Sir David for his generous offer. A balance-sheet of the recent electrical exhibition was produced showing a net profit of £108. The gas company were requested to comply with the statute, and give notice before breaking up the streets in future in order that precautions may be taken to prevent damage to the electric light mains. The question of additional lighting in the side streets was referred to a sub-committee. The Local Government Board wrote sanctioning the loan of £12,000 to be repaid in 25 years. The borough surveyor was instructed to prepare plans for extending the central station, and the consulting engineer to obtain tenders for the new machinery required. It was decided not to employ a clerk of the works, but to place the matter in the hands of the resident engineer. Mrs Pierson wrote that her well in Cumberland-walk had dried up since the sub-station was built, and claimed compensation, but the committee informed her that they could not accede to the request.

Fareham (S. Hants).—At the monthly meeting of the Fareham Urban District Council the question as to what course should be taken in consequence of the recent action at law between the Council and the electric light company having gone against the former was considered. It will be remembered that the judgment was that the Council had to pay damages (£3,800) and costs, but time was given the Council to decide whether they would pay up or take over the undertaking. The meeting of the Council was largely attended by the ratepayers, and considerable heat was displayed by them during the debate. The Chairman said there had been a meeting to talk over and decide some line of action. He had told Mr. Blake that he intended to do one thing, and that was, take the wish of the ratepayers, not by public meeting, but by taking a poll of the town. The clerk read a report on the value of the electric light company's undertaking, prepared by Messrs. S. Z De Ferranti and E. Manville, electrical engineers, who expressed the opinion that the undertaking was a losing concern, with no prospect of ever becoming a paying concern. If the local authorities took it over, they considered this could only be justifiably done on the basis of what the plant would fetch if sold by public auction. Under the most favourable circumstances they valued the plant at £1,450, with £300 the cost of obtaining the provisional order. If the plant were purchased by brokers, it would not fetch more than about £750. Messrs. Ferranti and Manville, having assessed each item in the schedule attached to the proposed contract at what they considered a fair trade price, valued the whole thing as a going concern at £3,164, and they could not understand how it was the arbitrators assessed the concern at so high a figure as £4,866. If the Council took the undertaking over, the Board of Trade would be almost certain to order that the wires be put underground, and duplicate machinery provided, whilst the Local Government Board would not sanction a loan for more than seven or eight years. Mr. C. B Smith said the report just read fully justified the Board's action. If they purchased, it would mean a future lighting rate of 1s in the pound, whereas if they refused they would have to pay one rate of 4s. in the pound, but they would get it back in the course of six years in the reduced lighting rates The Chairman then proposed that before deciding whether to pay the damages or to accept the offer made in court by the company to complete the purchase of the undertaking, a poll of the parish be taken as provided by the Local Government Act, 1894, for the election of councillors. The resolution was put and carried. The poll was fixed for December 21, between the hours of 8 a m and 8 p.m., and the chairman was appointed returning officer.

Stafford.—The Estates and Works Committee of the Town Council have recommended that permission be granted to the National Telephone Company, Limited, to affix 16 additional wires to the standard on the Guildhall, as, owing to the transfer of the trunk lines to the Government early next year, the wires would have to be carried to the post office for the public use. Mr. Smallman, in moving the adoption of the report, said the committee had considered as to the lighting in the Market-square, and recommended that two electric arc lamps be erected therein, the two gas lamps outside the Guildhall being entirely dispensed with. The arrangement was that the gas lamps in the square should only be lighted at 11 30 at night, when the arc lamps were switched off, the increased annual charge being £11. 10s. The committee also considered as to the arc lamps in the Gaol square and Foregate street, and recommended that they be taken over as part of the public lighting as from January 1 next, the gas lamps in the neighbourhood being lighted when the arc lamps are switched off; the increased annual charge in this instance would be £27 10s. He added that the present cost of lighting the Market-square was £33. 10s per annum, and that the total extra cost of the new arrangement would amount to £39 yearly The report was adopted. With regard to the proceedings of the Gas and Electricity Committee, the Mayor, Alderman W. H Peach (chairman), and Alderman W. Silvester (vice-chairman) were appointed a sub-committee to confer with representatives of the County Council as to the charge for electricity supplied to the new county buildings. The committee submitted for approval a scale of charges in connection with the supply of electricity: hire of meters, to register 5 or 10 amperes, 5s. per quarter; 20 or 25 amperes, 6s. per quarter; 30 or 50 amperes, 7s. per quarter; making service connections, not exceeding 10 amperes, £2; 25 amperes, £3; and not exceeding 50 amperes, £4 Alderman W. H Peach moved the consideration of the report. With reference to the price to be charged to the County Council for electric light, nothing had yet been arranged. Alderman Goodall seconded the proposition. Mr. Lovatt complained that the charge for electric meters was excessive, and moved that the question be referred back to the committee Mr. F. Amies seconded the motion. Alderman W. H. Peach pointed out that the sum fixed upon was 10 per cent. on the cost, and was based on the same principle of charging as the gas-meters. The charge for making the connections was just about the actual cost to the committee. Mr. W. O. Rooper supported Mr. Lovatt's motion. If the committee wanted the electric light to become popular they ought to make every possible concession, especially in the case of small consumers, who would no doubt regard the charge for meter rent as a very heavy one, and might in consequence discontinue taking the light at Easter until October. Alderman Lloyd hoped that the promise given that the greatest endeavour would be made to make the electric lighting a paying concern would be fulfilled. Alderman W. H. Peach undertook to report to the next meeting of the Council what the charges were in other towns, and the report as amended was adopted.

The Liverpool Overhead Railway Extension.—It is expected that before 1896 begins its course the heading of the tunnel at the South-end for the extension of the electric railway will be driven through the Herculaneum Dock to the Dingle terminus. Only about 60 yards have now to be pierced in order to accomplish this. The extension of the overhead railway will be very different in its character from the original portion. The line that sweeps along the length of the docks of Liverpool is carried nearly every yard of its way upon an iron viaduct a good height above the level of the street. But the extension burrows all the way through the soft red sandstone rock which rises above the Mersey where the south docks have been constructed; and the Dingle terminus,

Digitized by Google

which will be adjacent to the Dingle tramcar terminus, will, with the exception of the ticket and station offices, also be beneath the surface. The contracts for the extension were entered into during the earlier part of the present year. Messrs. H M. Nowell and Co., of Leeds, secured the contract for the tunnel; and Messrs. Pearson and Knowles the contract for the viaduct connecting the present line with the tunnel and bridging over the lines of the Cheshire Lines Committee. They are not losing any time in securing the execution of the work within the stipulated period, and the expectation of Mr. Cottrell, the general manager of the overhead railway, is that the public will be using the extension early next summer. The present southern terminus of the railway is at the Herculaneum Dock. The extension begins on the left, about 150 yards to the north of the Herculaneum Station, and bends in a south-easterly direction across the lines of the Cheshire Lines Committee, being carried over these by a lattice girder bridge, 2oft. deep, of one span of 220ft., this being the largest span of a railway bridge in or near Liverpool. There is as yet not much evidence of the bridge, but the material is in a forward state of preparation, and when once the work is begun a comparatively short time will be required to erect it and lay the permanent way over it. The boring of the tunnel by Messrs. Nowell and Co. from that point to the Dingle is being done in sections, and a considerable portion is already cut out to the full size 26ft. by 20ft (to the crown of the arch Shafts were sunk in Shorefields (belonging to the Midland Railway Company), in Parkhill-road in Hurry-street, in Arthur-street, and at the Dingle terminus. and when the requisite depth had been reached headings were driven each way. The headings have all met with the exception of those between Arthur-street and the Dingle, which are now only about 60 yards apart; and as the Shorefields, the Parkhill-road, and the Hurry-street shafts have served their purpose they have been filled up again The enlargement of the heading to the full size of the tunnel is also being done in numerous sections. There will be a brick lining of the arch of the tunnel throughout, and, as the rock is of varying quality, the necessity of starting the lining from the floor of the tunnel, or from the spring of the arch is determined by the engineer and contractors as they proceed. As some evidence of the rate with which the work is being executed it may be mentioned that during last month 55 yards of the tunnel were completed, with the brick lining, etc., and that 200 yards more will have been similarly dealt with during the present month. The excavation at the Dingle end will be 52ft. wide in order to allow spacious platforms to be constructed. The intention of the directors of the overhead railway, the *Liverpool Courier* says, is to construct a new station on the existing line opposite the Wellington footbridge, and to use the end of that line as a carriage shed. The new station will be extremely convenient to the adjacent portion of Toxteth, which is built on the top of the rock, for a footbridge connected with the Wellington-street footbridge will carry them into the station without the descent and ascent of steps that are now necessary. There will be no other station until the Dingle terminus is reached. When the extension is completed the north and south of the populous district along the line of docks will be connected by a splendid and direct line of access, which cannot fail to increase the already great usefulness, as well as undoubted popularity, of the overhead railway.

PROVISIONAL PATENTS, 1895.

DECEMBER 2.

23002. **Improvements in electrical batteries.** Frederick Hanson Perry, 12, Cherry-street, Birmingham.

DECEMBER 3.

23083. **An improved armature for dynamo-electric machines.** Edwin Hodgson, James Walker, and Arthur Blackburn, Whitcliffe, Cleckheaton.

23097. **Improvements connected with the electrical deposition of zinc.** Richard Heathfield and William Stepney Rawson, 1, Leadenhall street, London.

23109. **Improved electric switch for key, socket, main, or ordinary switches.** Walter Mills Close, Hatchford, Cobham, Surrey.

23111. **Improvements in electric incandescent lamps.** Henry Francis Joel and Ferdinand Fante, 1, Arundel-street, Strand, London.

23165. **Improvements in and relating to galvanic batteries.** Audley Charles Miles and Bernhard Fritz de Morgenstern, 151, Strand, London.

DECEMBER 4.

23174. **Improvements in electric arc lamps.** John Hewett, 8, Great Portland-street, London.

23189. **New pantelegraph for transmitting in facsimile autographic telegraphic messages in handwriting, print, sketch, design, etc.** Harry Adrian Schlesinger, as agent for Louis Sandos, 10, rue des Voirons, Geneva.

23250. **Improved paste-carrying plates for electric accumulators.** Friedrich Wilhelm Schneider, 18, Buckingham-street, Strand, London. (Complete specification)

DECEMBER 5.

23259. **An improved reflector for incandescent electric light globes or bulbs.** Samuel Rowbottom and John Roe, 64, Barton-arcade, Manchester.

23338. **Improvements in or relating to electric arc lamps.** Henry James Fisher, 70, Chancery-lane, London.

23354. **Improvements in electric heating devices.** Fernand Le Roy, 6, Lord-street, Liverpool. (Complete specification.)

DECEMBER 6.

23404. **Improvements in electric motors.** Felipe Zapata, 31, Homefield-road, Chiswick, London.

23415. **Improvements in or relating to electric arc lamps.** Moïse Freudenberg, 45, Southampton-buildings, Chancery-lane, London.

23416. **An electric door fastening.** Samuel Flood Page, 28, Southampton-buildings, Chancery-lane, London.

23426. **Improvements in electric signalling.** Reginald Belfield, 31, High Holborn, London.

DECEMBER 7.

23459. **Electro-depositing on and stripping gold from cathodes.** Emile Andreoli, 147, Coldharbour lane, London. (Complete specification.)

23462. **Improvements in the striking and regulating mechanism of arc lamps.** Haldane Gwilt Cotsworth, 14, Station-road, Swindon.

23496. **Improvements relating to electric railways.** Reginald Belfield, 31, High Holborn, London.

23515. **Improvements in the manufacture of electric cables.** Arnold François Borel, 45, Southampton-buildings, Chancery-lane, London.

23519. **Improvements in electrical insulators and insulating compositions** Alfred James Perton Whitaker and Frederick Gwilym Treharne, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1895.

107. **Primary batteries.** Levetus and others.
437A. **Arc lamps.** Barton. (Jandus.)
1906 **Electric condensers.** Threlfall. (Threlfall.)
11728. **Electric switches.** Shaw.
13900. **Galvanic batteries.** Gordon.
19104. **Electric rail-bonds.** Buxton.
19204. **Electric signalling.** Gibson.
19318. **Telephone and signalling systems.** Smith and Vasar.
19461. **Thermo-electric generators.** Cox.

NOTES.

Argon.—The Académie des Sciences has awarded the Lecomte prize of 50,000fr. to Prof. Ramsay and Lord Rayleigh for their discovery of argon.

Theories of Electrolysis.—Under this title Mr. W. C. Dampier Whetham, M.A., Fellow of Trinity College, Cambridge, contributes an article to the current number of *Science Progress*.

Naval Signals.—The sloops "Algerine" and "Phœnix," which are being completed for sea at Devonport, are, it is stated, to be fitted with semaphore electric lights for masthead signalling at night.

Tramways in Persia.—Herr Felix Moral, who is said to represent a syndicate of German firms, has obtained a concession for the construction and working of a steam or electric tramway from Teheran to the villages north of the city, a distance of about 10 miles. The concession is valid for 90 years.

Gas Again.—The Rev. Evan Hurndall, the well-known Congregational minister, and Mrs. Hurndall, were found unconscious in their bedroom at Westminster last Sunday morning, having been overpowered by an escape of gas during the night. Mrs. Hurndall soon recovered consciousness, but Mr. Hurndall remains in a critical condition.

Memorial.—A meeting of Cork citizens has been convened by the Mayor of that city for the purpose of taking steps to perpetuate the memory of the late Mr. Denny Lane, M.A., and it was eventually resolved to form a committee with the view of collecting subscriptions in order to provide a suitable memorial. The Cork Gas Consumers' Company has headed the list with a donation of £100.

Electrotechnics in Chili.—It is stated that the Chilian Government, having decided to establish an electrical section at the Escuela de Artes y Oficios, mainly with the object of familiarising naval engineers with the principles of electrical engineering, has engaged as instructor Dr. Fritz Mumme, late of the Aktien-Gesellschaft vorm. Schuckert und Co., who has departed for Chili accompanied by two working assistants.

New Arc Lamps.—The active movement in the construction of new designs of arc lamps still continues. Lamps with downward burning shadowless arcs (the negative pencil being placed at an acute angle to the positive) are not new, yet a Berlin firm—Niewerth und Co.—seems to have worked a patent on this principle through the once impregnable German Office; and the lamp constructed on their system is described and illustrated in the *Elektrotechnischer Anzeiger* of December 8.

Telephones in Iceland.—The telephone has apparently got a footing in Iceland. It is said that an American is laying a line between Reykyavik and Akureyri at a cost of 100,000 kr. It is also reported that an Englishman has submitted to the Althing a proposal for a telegraph cable between Iceland and the Shetland Islands. The estimated first cost of the latter, 1,800,000 kr., and the annual maintenance charges of 180,000 kr., the contractor believes would be partly covered by Iceland, Great Britain, France, and North America respectively.

Harnessing the Tides.—What is probably the first serious attempt to utilise the energy of the tides is now being made on the Pacific coast at Santa Cruz. A dynamo, to cost about £4,000, is now being placed in position. It will be worked by a head of water raised by the tide, and the electrical energy thus obtained will be employed in lighting the town and in driving the street cars. That, at any rate, is the idea, although whether it can be successfully carried out remains to be seen. The apparatus will be completed, and, it is expected, in full operation, early next month.

Telegraphs and Telephones in the Sahara.—According to the *Kölnische Zeitung*, M. Bayolle, an engineer at the head of a telegraphic expedition travelling from Biskra to Tuggurth, telephoned on November 18 from his camp, 11 miles away, to Biskra. He said that he expected to reach Tuggurth by the middle of December, but that he was experiencing great difficulties with the camels carrying the telegraph poles. The animals were not accustomed to such lengthy burdens, and they frequently lied down in the road and coolly refused to budge an inch with their load.

The American Pacific Cable.—Senator Carter has introduced a Bill into the United States Senate authorising the Pacific Cable Company of New York to co-operate in the laying of a Pacific cable to Japan by way of Hawaii, the United States Government agreeing to pay an annual subsidy for 20 years at the rate of 25dol. per mile on a distance not exceeding 7,250 miles. The Bill also provides that United States Government messages shall be given the preference, that they shall be carried free for 20 years, and that in case of war the line shall be placed in possession of the United States.

Which is it to be?—We observe that the London *Times* has lent the weight of its authority to the word "autocar," which it now prints without the significant inverted commas but with a hyphen, "auto-car." We believe that the vocable originated with a journal called the *Hardwareman*, which succeeded in obtaining the powerful support of the *Engineer* for its offspring. As for ourselves, being linguistic purists, we do not care for hybrid constructions—"auto" is Greek, while "car" is Latin and Celtic. At the same time, such clumsy phrases as "horseless carriages," "mechanical road carriages," and "self-propelled vehicles" are not meeting with general favour. Why not therefore adopt the philogically sound "motor-car," which could be run into a single word, "motorcar"?

The New Atlantic Cable.—A Paris telegram says that the Budget Committee has approved the draft convention concluded between the Government and a French cable company for the laying of a new cable between Brest and New York, with an extension to the West Indies, and thence to Para, in Brazil. The committee declined, however, to sanction M. de Mahy's proposal for a cable between Réunion and Mauritius, their view being that all such schemes should be initiated by the Government. The *Débats* comments on the tenacity shown by Great Britain, despite Brazilian protests, in regard to the possession of the Island of Trinidad, "which will be for her South Atlantic cables what Bermuda is for her North Atlantic ones," and it adds that Mr. Chamberlain is showing an active interest in the scheme for a cable between British America and Australasia, "which will crown the practical cable monopoly possessed by England."

Lightning Freaks.—In South Devon, shortly before 10 o'clock on Wednesday morning, two brilliant flashes of lightning were followed by peals of thunder. In a field near Plymouth, which is used as a rope-walk, an "electric ball" was seen. It is described as travelling from west to east, tearing up the ground for 100 yards in its course until it reached the place where two men and a boy were employed in rope-walking. It shattered the lower part of the door of a small house occupied by the spinning wheel, knocked a hole in the wall on the opposite side, and then, passing upwards, partly unroofed an adjoining building. It next passed along another rope-walk where four men were working. One of these, named William Morey, was unfortunately instantly killed, and two others were knocked

Digitized by Google

down. One, named James Lowe, was seriously injured, and his condition is described as critical. Fishermen report that on Monday night, while they were at sea, they observed "fireballs" in their masts and rigging.

Progress in Electric Lighting.—At the monthly meeting of the architectural section of the Philosophical Society of Glasgow, Mr. David Hunter, a member of the Institute of Mining Engineers, read a paper on "Progress in Electric Lighting." He showed first light from acetylene gas obtained from the new compound calcium carbide, made from a combination of lime and coal dust fused together in an electric furnace, and proceeded to say that Nature was economical in all her methods, but in man's method of burning coal a ridiculously small part of the energy was converted into light. The energy delivered from coal by means of an engine to a dynamo was only 3·62 per cent., and the efficiency of the latter was such that about 78 per cent. of that was delivered to the consumer. The present incandescent lamp was very inefficient and wasteful, great part of the energy going into heat. The most difficult problem in lighting a considerable area was the distribution of the current energy among the consumers.

The Wiring Question.—Our contemporary the *Builder* has now taken up the wiring question. In the course of an article it says: "Electricians are beginning to realise that wood casing is by no means a perfect way of conveying electric wires to lamps in house wiring. We have often had occasion to point out that this method is very unsightly. There are many hotels and other buildings which have been wired without the slightest attempt at preserving appearances, as if getting at the place where the lamp is to be fixed by the shortest route over moulding and cornice was the main consideration. Again, where the wood casing is concealed there is often a reckless cutting at joints by the so-called wiremen, to the possible weakening of the building. To guard against this, architects should always make ample provision in the way of conduits or channels for the electric light or power wires. It would be a great boon to fire insurance inspectors, as at present any inspection of electric wiring after it has been closed in by lath and plaster is of no value."

"The Fruits of Monopoly."—A correspondent writes under this head to the *Times*: "Some weeks ago I wrote to the National Telephone Company and requested that they would connect my house with the exchange with as little delay as possible. The manager replied that the work could not be finished under about six weeks, in consequence of some alleged difficulty about 'wayleaves' in the part of the town (Belgravia) in which I reside. I thought the delay unreasonable, but having, of course, no option, I gave the order to proceed. At the end of eight weeks there was still no sign whatever of my telephone, and, tired of waiting, I countermanded the order for it, and am instead connecting my house with the District Messenger system, which, if less convenient than the telephone, will to some extent supply the place of it, and will anyhow be installed without unreasonable delay. I have lately come from a country where the convenience of the public is a matter of first consideration, and I am inclined to think that, under the wholesome influence of competition, eight days, let alone eight weeks, would have sufficed for the work in question." Comment is needless.

Artificial Rubbers.—A substitute for indiarubber has been devised by M. E. Desprez, of Paris. Guttapercha in sheet form is taken and covered on one side or both sides with a close-meshed fabric (wire gauze may be used for some purposes) and the whole is conglomerated by pressure under heat, and sawdust or other suitable and cheap substances may be incorporated. An artificial rubber of more or less strength may also be obtained by dissolving four parts of nitro-cellulose in seven parts of bromo-nitro-toluol. Upon varying the proportion of the nitro-cellulose, a material may be obtained that possesses elastic properties and closely resembles indiarubber and guttapercha. If desired, nitro-cumol and its homologues may be used instead of bromo-nitro-toluol. As the base of a product designed to replace indiarubber and guttapercha, M. Le Brocquy, says the *Revue Scientifique*, proposes to employ the composition used for making printers' rollers—that is, a mixture formed of variable proportions of glue, glycerine, and molasses. This composition is to be covered with canvas, ordinary rubber, or any other material suitable to protect it against humidity, great heat, or any mechanical action.

The Cantor Lectures.—In his third and last lecture on "Mechanical Road Carriages," delivered at the Society of Arts on Monday night, Mr. W. Worby Beaumont discussed some of the recent developments of the subject. After referring to the interest taken in these road carriages in France, he remarked that in England legal restrictions had kept down an industry in which we ought to be a long way ahead of France, instead of being a long way second, seeing that 60 years ago Englishmen proved practically that steam road carriages could be made a commercial success. He then mentioned some of the motors more recently employed to drive these carriages, describing the oil motors of Butler, Knight, Daimler, and Benz, the electric cab and omnibus of the Radcliffe Ward Company, and the successful steam motor and boiler of Serpollet. Some of the points that should be borne in mind by the designer of road carriages were next touched upon. If we made light carriages that required both a driver and a stoker, our machines would be inferior to those of the French. The vehicles must demand little skilled attention if they were to be generally used. It was a question whether high speeds were necessary, and it was no good to make machines with a capacity for high speed which could not be utilised.

The Rating of Telephone Wires.—On Monday last the special sessions for South London sat at the Newington Court House for the purpose of hearing the appeal of the National Telephone Company against the valuation lists of the parishes of St. Mary, Newington St. Saviour's, Southwark; and St. George-the-Martyr. Sir George Morrison, who appeared for the National Telephone Company, said there had been no legal decision as to the principle on which telephone wires should be rated; but the local authorities had hitherto apparently valued the wires on the mileage, which was not applicable to a business of this nature at all. Mr. Horace Avory (with whom was Mr. Bassett Hopkins), on behalf of the three parishes, produced evidence to show that there was no other way of arriving at the value than by taking the mileage. At the quinquennial valuation in 1890 the Assessment Committee had put the assessment at 30s. per mile, but, in view of the increase of business, it was in 1895 made 49s. per mile, and he contended that it ought to have been a great deal more. The case occupied the whole day, and the Court dismissed the appeal without costs, as important questions of principle were involved. Sir George Morrison stated that as this rating applied to the whole of the United Kingdom the company would consider whether they should appeal to a superior Court.

The Pingault Electric Pacemaker.—M. René Arnoux, at the meeting of the Société Internationale des Electriciens on December 4, described the Pingault electric pacemaker bicycle. In view of the paper of M. Arnoux there was a larger attendance than usual. The bicycle, the constructor of which is M. G. Richard, has

Digitized by Google

been designed with the view of improving the pacemaking on track runs where the pacemakers have to be changed every few laps, with the result that the pace is altered at every change. Riding the Pingault cycle, one man can make the pace for an hour at a stretch at speeds up to or beyond 50 kilometres (31 miles) an hour. The machine is driven by the rider in the usual way by pedals and chain, but an auxiliary source of power is provided by two electric motors behind the saddle. These motors are both mounted on the same shaft, and drive a wooden wheel acting directly on the pneumatic tire, an arrangement which obviously permits of an exceedingly great angular velocity in the motors. The current is derived from accumulators carried in a box mounted in the frame between the rider's legs—apparently very much in the same manner as a travelling-bag. The accumulators are split up into four batteries, any or all of which can be switched on according to the speed desired. The switch is on the handle bar, but no details of the accumulators are given, though it is stated that they give 25 watts per kilogramme (11·3 watts per pound). The total weight of the machine, including the accumulators, motors, and fittings, is 90 kilogrammes (about 200lb.), but this has been somewhat reduced in a later design. As *L'Industrie Electrique* (December 10) remarks, the practical application of the accumulators used by M. Pingault will be awaited with impatience if they can maintain the efficiency above stated.

The International Congress of Applied Chemistry.—The first meeting of this body was held in August of 1894 at Brussels and Antwerp, and the second has been arranged to take place in Paris next year under the patronage of the French Government, and will be accompanied by an exhibition of chemical and agricultural industries organised by a separate committee. The congress will be divided into 10 sections, of which the last, Section X., is devoted to electro-chemistry, and will be presided over by M. Moissan, membre de l'Institut. The secretary is M. Gosselin, of the Ecole Centrale des Arts et Manufactures, and among the vice-presidents are MM. d'Arsonval, Hospitalier, Javaux, Mascart, etc. The following is the programme of subjects to be discussed: 1. The laws of electrolysis, with the determination of the constants involved (the resistance of electrolytes in solution and in a state of fusion, the effect of temperature, the E.M.F. of polarisation, etc.). 2. The use of electrolysis in analysis. 3. (*a*) The preparation and use of insulating materials, including indiarubber, guttapercha, and their substitutes; (*b*) the resistance, temperature coefficient, and electric properties of alloys. 4. Electrolysis in the alkali trade (chlorate of potash, soda, bleaching powder, etc.). 5. The use of electrolysis in organic chemistry (rectification of alcohols, sugar manufacture, sterilisation of impure water, synthesis of organic compounds, etc.). 6. Electrolysis of metals in the wet way. 7. Electrolysis of fused salts (sodium, magnesium, silicon, lithium). 8. The electric furnace (carborundum, calcium carbide, silicon boride, titanium, etc. 9. Thermo-electric work (welding, electric heating, etc.). The address of the treasurer of the congress is 156, Boulevard Magenta, Paris, and the fee for admission is 10fr.

Gas v. Electric Light.—The correspondence on this subject in the Kentish papers between residents of Tunbridge Wells and Hastings, with an occasional letter thrown in by secretaries of incandescent gaslight companies in London, continues with unabated energy. A Tunbridge Wells correspondent, who signs himself "Economy," sums up the case against the incandescent gaslight so neatly that we cannot refrain from quoting a portion of his letter. He says: "I have been somewhat surprised and amused at the trouble and expense the supporters of the ancient illuminant 'gas' have gone in this town to endeavour to upset the Corporation electricity scheme. I regret in many cases the opposition has been nursed by worthy members of the Council, who are elected by the ratepayers to study their interests. Undoubtedly, they must have overlooked this fact in their eager desire to protect their own, to the disadvantage of the former. However, I for one would be sorry to stop them, since they are really doing all they can to help the scheme by giving it a free advertisement, since any intelligent reader would reason thus: 'Another letter against the electric light! How frightened all those who have an interest in our local gas company seem to be, and for what reason?' The answer is clear: because they know the electric light is much superior to gas, and no more expensive; otherwise, why should they trouble themselves? However, at the present time there is no need for the gas company to be alarmed, as they are bound by the laws of progress to give way to the superior illuminant. It would be more sensible for them if, instead of 'kicking against the pricks,' they were to spend their surplus energy in looking for other sources to obtain their income. The time is not far distant when that income derived from cooking, heating, and gas-engines will also be swallowed up by electricity. Already electric cooking and heating stoves, as well as electric motors, are being installed on account of their convenience and cleanliness. The 'incandescent gas' may be considered one of the stepping-stones between an ordinary gas-burner and electric light, as there is nothing more sure to eventually lead to the adoption of the modern illuminant than installing the incandescent gas. The fact of a consumer changing to it shows his dissatisfaction for ordinary gaslight, but, being more or less conservative in principle, he does not like to effect a radical change all at once, and therefore puts in the 'incandescent gas,' to follow at some future time with the electric light, whereas he might have saved himself the preliminary expense. I have been often puzzled over the policy adopted by the various gas companies in persuading their clients (and in many cases effecting the necessary change free of cost) to adopt the incandescent gas, which is in direct opposition to their own interests, since according to their statement it consumes less gas, and gives more light than an ordinary 16-c.p. burner, or, in other words, reduces their own income considerably! Their clients ought indeed to be thankful for their philanthropic motives! They might go further, and inform them of its little eccentricities, such as the mantle breaking with a breath of air, or on lighting it with a match, necessitating the use of a by-pass which burns gas all the 24 hours. This prevents a timid consumer from turning his gas off at the meter every night (a very wise precaution in case of fire), and last, but not least, the rapid rate at which the brilliancy vanishes as the age of the mantle increases, meaning the replacing of the same frequently. They might also recommend it to the fair sex for its peculiar greenish hue."

The Accumulator Question.—The first trial by the American Institute of Electrical Engineers of the feature of topical discussion, remarks the New York *Electrical World* of November 30, was an unqualified success, and it will, most probably, regularly figure hereafter on the yearly programme. The several communications read at the institute meeting, and the discussion which followed, undoubtedly form the best contribution yet made in America to the practical side of the subject of storage batteries. The papers of Prof. Crocker and Mr. Childs resume in detail the various uses to which they are

Digitized by Google

applicable, the former adding also the disadvantages, and the latter giving much information on points of practical interest. Mr. Hering's remarks bring out the advantages of the Planté type of cell, and refer more particularly to traction batteries, in regard to which he discusses the important question as to the relation which should exist between the life of a cell, its cost and weight, in order to attain the most economical service. Those who complain that the storage battery has been too much coddled, and that reference to any of its faults has been considered in the light of *lèse majesté*, will find no reason to complain of the treatment accorded it by Mr. Perry, who argues that the gas-engine is more economical for many purposes for which the storage battery has been claimed to be exclusively applicable. It is undoubtedly true that the gas-engine has been neglected in the United States, and that it has a most promising future everywhere. The fact remains, however, that in Germany — where the gas-engine has received widest adoption and its advantages are most clearly recognised, and where, moreover, the question of central-station auxiliaries has been most carefully studied— the storage battery has not been appreciably affected by its competition. The favourable testimony borne by Mr. Edgar as to the advantages of storage batteries in central-station work is particularly effective on account of being based upon actual experience. While the results that have been obtained in Europe should cause no doubt to be entertained as to the economy that may be obtained from their use in this connection, yet the lack of experience under the conditions of American practice has discouraged interest in the subject. With the satisfactory results gained at Germantown, Merrill, Wis., and Boston, details of which are now accessible, central and power station managers are brought face to face with the situation, and can no longer afford to delay investigation as to how it affects their interests. In the discussion our contemporary notes that in one place the storage battery was spoken of as having an ampere efficiency of 96·1 per cent., and a watt efficiency of 84 per cent. The absurdity of speaking of ampere efficiency is so generally recognised that it is surprising to find the term employed in a discussion before the American Institute of Electrical Engineers. While perhaps all of those at the meeting know that the term carries no real significance whatever, if used, however, in presenting the subject of the storage battery to others of less technical knowledge, the result will merely be to excite suspicion with respect to other statements. For it is not difficult to conceive that if an intended purchaser, not knowing the distinction, is told that a battery has an ampere efficiency of 96 per cent. and a watt efficiency of 84 per cent., he will not be favourably impressed by the double statement, and may be inclined to believe that there are perhaps still other efficiences on the descending scale of which he is not told. The only efficiency that should be used, our contemporary adds, is the one which denotes the ratio between the energy taken out of a battery and that put in—the watt efficiency—for that is the only practical, as well as the only true, efficiency.

Electrical Communication with Lightships.— It was an interesting tale that Mr. Hobbs, of Ramsgate, unfolded at the public meeting which was held at Deal the other day in favour of electrical communication between the Goodwin lightships and the shore. Mr. Hobbs said that he advocated such means of intercourse 14 years ago. At that time he was looked upon as a madman, and the authorities treated him so, and he holds a letter from Lloyd's showing that they would not allow his petition sheets to lie on their table for signatures. Again, he had a crowded meeting at Ramsgate, and the sailors there were disgusted with his idea. They said it was impossible, and that nobody but a madman would propose such a thing. He told them it would be done, but they amused themselves by pelting the good chairman (Sir George Bonner) with peas. They, however, passed a unanimous resolution and got up a national petition, and it was presented by Lord Brassey on August 2, 1891. He had to see several members of the Cabinet, and happened to meet Mr. Fawcett. "What, electrical communication! Why it is the very thing we want," he said. "Come with me, and I'll take you to see Mr. Chamberlain." Mr. Hobbs thereupon had a long interview with that gentleman, who, after having explained to him the circumstances of four wrecks, ejaculated, it is said, "Why, I never understood it like this before. Forward the petition, and I will do my very best for you." Mr. Hobbs remarked that if all the members of the Cabinet and of the Board of Trade had about six hours on the Goodwins, he would be bound to say they would shriek for the communication till they were hoarse. He then went down and saw Sir James Douglas, engineer to the Trinity, who said Mr. Chamberlain had been down, and that they were in earnest, and he said he would do what he could to help him. They eventually got the report of the Board of Trade Committee (who laid the cable from Walton-on-Naze to the Sunk Lightship), and the Right Hon. Mr. Akers-Douglas helped him nobly in the House of Commons by putting questions, presenting petitions, and advising him. Finally, the Board of Trade declared that they would connect the four Goodwin lightships in six weeks, and he had the estimate before him, showing that they were in earnest. Nobody knew how Colonel King Harman was hurt when he came to Ramsgate to announce to him (Mr. Hobbs) that the committee had made up their minds not to connect the lightships on the ground that it would cost too much! The speaker then referred to a plan of Denmark, dated seven years back, showing that the whole of the northern coast of that country was connected by electric cable. He asked his audience, in the name of common-sense, whether it was right for England, the largest maritime country of the world, to be kept behind by red-tapism. Some two or three years ago a Royal Commission was appointed to investigate the matter, and through their influence and recommendation, and the assistance of the two Governments in voting the money, they now had 52 lightships and lighthouses connected out of 244. The Postmaster-General allowed them to send a message from any of the 52 lightships to the shore for 10d., and then they had to pay the ordinary expense for transmission on the land. They now asked the Postmaster-General to accede to their request to allow any message to be sent—by all means pay the men for sending them. They would see, Mr. Hobbs said in conclusion, what a revenue could be obtained when the Blue-book told them that since the experiment was tried at the Sunk Lightship nearly 30,000 vessels had signalled in passing. In the end the following resolution was unanimously carried: "That this meeting is convinced that there is annually a great loss of life and property arising from the want of sufficient communication between the several lighthouses and light-vessels and lifeboat stations situated round the coast of Great Britain, especially between the Goodwin Sands lights and the shore, and that it is a matter of urgent necessity that electrical communication should be established between all the Goodwin light-vessels and the shore, in order to send messages to those ready to come to the rescue of all who are likely to perish."

WALSALL ELECTRICITY WORKS.

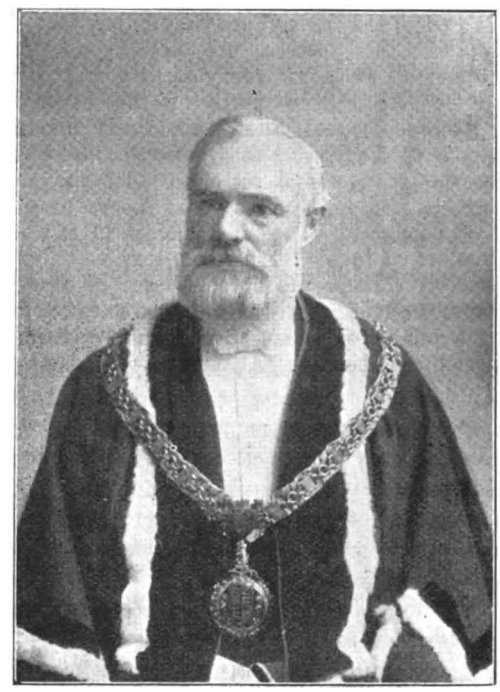
The history of the electric lighting movement in Walsall extends back as far as 1882. In that year a company from Birmingham obtained powers under the Electric Lighting

MR. JOSEPH NOAKE, J.P., MAYOR.

Acts then in force for supplying the town of Walsall, but, as was the case in nearly all the companies started about that time, no work was done, and the powers consequently lapsed. In 1890 the Corporation applied for and obtained a provisional order, and decided to retain Mr. F. Brown as their electrical adviser. Mr. Brown accordingly, in 1891, prepared a scheme for lighting the central parts of the

MR. J. R. COOPER, TOWN CLERK.

borough, and allowed for sufficient plant to maintain about 6,000 8-c.p. lamps alight at one time. About this time the electric tramway was being equipped by the South Staffordshire Tramway Company. The supervision of the work on behalf of the Corporation was also placed in Mr. Brown's hands. This necessitated a visit to America to inspect the electric lines working there. Early in 1892 the report and scheme for electric lighting were laid before the Council, and, finally, tenders asked for. The matter, however, did not proceed much further till the end of 1893, when amended tenders were sent in. At the



MR. T. P. BROWNHILL, EX-MAYOR, AND CHAIRMAN OF COMMITTEE.

enquiry held before the permission to borrow the necessary money was granted by the Local Government Board, it was stated that the population of Walsall stood at 75,000 according to the most recent estimate, and was rapidly increasing. The estimated ratable value was £151,210. In the scheme, the area of supply was the whole of the borough. The borough is of a very scattered character,

MR. F. BROWN, CONSULTING ELECTRICAL ENGINEER.

the total length being about seven miles, and an average breadth of about three miles. There are over 60 miles of public highways inside the boundaries. There was then no application before the Corporation from any person or company within the area to provide electric lighting. Mr. Frederick Brown had then been called in by the Corporation as consulting engineer. It was his advice, after having inspected some of the chief electric lighting stations in

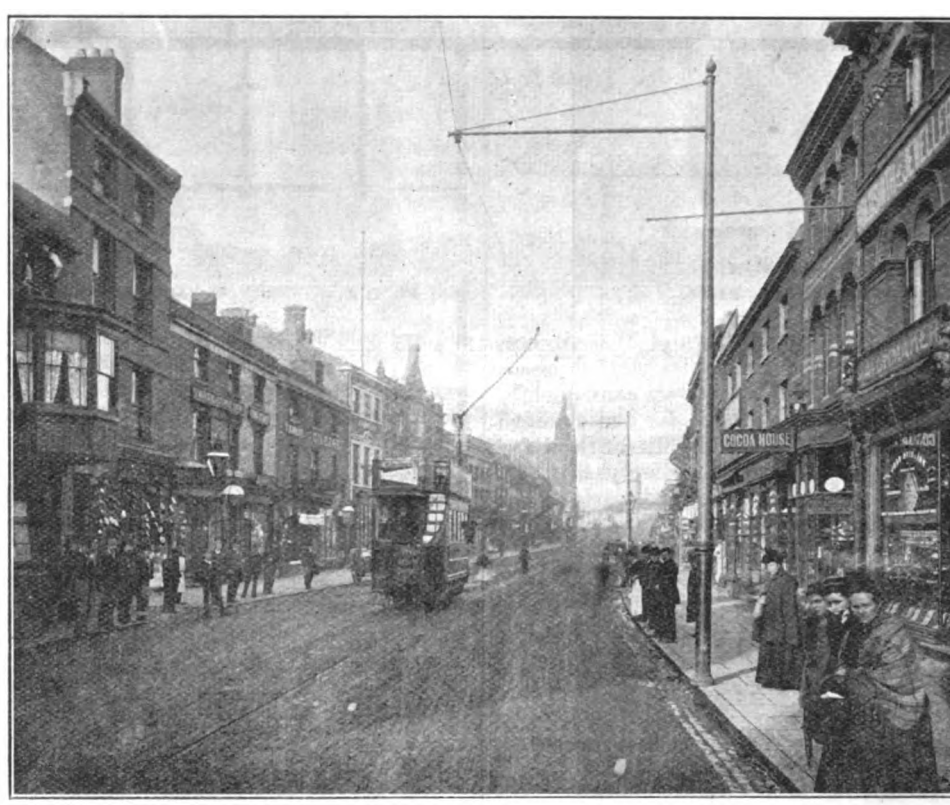
Digitized by Google

London and the provincial towns, that the continuous-current high-pressure system was best adapted to the town of Walsall.

Owing to the large area within the boundaries of the borough, a high-tension system must be used. For instance, the district of Bloxwich, lying to the north of the borough, is practically another town, containing about 12,000 people. In all probability there will be a demand made for a supply from that part of the borough, as we understand that the inhabitants of this district are not at all backward in their demands to have every facility and advantage possessed by the central parts of the borough. Mr. Brown, having decided that the direct-current high-tension system should be used, spared no trouble in designing the station and mains so that the first cost should not be too high nor should be reduced at the expense of efficiency. The chief points of advantage of this system are as follow: A widely-scattered district can be supplied, as voltages up to 2,000 can be used without trouble from the generators. Accumulators can be installed in a certain number of the sub-stations to supply the lightly-loaded periods of the day. At night, at all times except at maximum load, the generating station can charge the accumulators and supply the current required for the lamps on the mains at the same time. In this way, by adding the charging current to the lamp current, the supply station can be worked at fairly constant load, and hence more efficiently than with some other systems. Again, at heavy loads the accumulators in the sub-stations can be used to assist the continuous-current transformers. Perhaps the greatest advantage of this system over the high-tension alternating-current is that generating stations need not be worked more than eight hours a day, except, perhaps, in mid-winter, hence two shifts of men are saved. On the other hand, low-tension mains must be laid everywhere the demand arises, as isolated houses cannot be economically supplied from a high-tension distributing main. Thus low-tension mains will have to be laid throughout the scattered residential districts.

Site and Building.

As to the site of the works, the Corporation decided to appropriate part of the site of the Wolverhampton-street gasworks. Up to the present time the town has been supplied from two gasworks, both belonging to the Corporation—one at Wolverhampton-street, which is an old works established some 40 or 60 years ago, and the other a modern works at The Pleck, about 20 years old. The Corporation have abandoned the Wolverhampton-street works for the purpose of the manufacture of gas, but still use them as a storing station. About 2,370 square yards of this site is appropriated for the electric light department, and a more suitable position could hardly be found. It adjoins the canal, as can be seen from Fig. 1, and hence coal can be delivered direct to the wharf. Water from the canal will also be taken for condensing purposes as soon as the jet condensing plant is installed. The Local Government Board fixed the price to be paid to the gas department for this site at £90 per annum. Mr. R. H. Middleton, A.M.I.C.E., the borough engineer and architect, took the task in hand of remodelling the old buildings on the site to make them suitable for the reception of the electric lighting machinery. The old retort-house was used for the boilers, and a new roof was added to the adjoining building, which now contains the generating machinery. A section of this building is shown in Fig. 2. The rooms to the left are used as stores, men's room, test-room, etc.,



VIEW OF PARK STREET, WALSALL.

and beyond these, again, there is a tank-room, which holds the large iron tank for the feed water. The inside appearance of these renovated buildings forms a most striking contrast to the exterior views. Some idea of the appearance will be gathered from the perspective views of the engines and boilers. A dado of glazed and different coloured bricks has been built into the walls, and arranged with pleasing contrasts. A good top light has been provided by lights in the roof. A travelling crane, by Messrs. Tangyes, Limited, traverses the whole length of the engine-room, and is supported on long I-shaped girders resting on stone brackets let into the walls. Ample foundations were secured without a great deal of difficulty. The floors of the engine and boiler rooms are of wood blocks. The general arrangement of the plant and buildings can be seen from Fig. 1, and also the ample space provided in the buildings for extensions. The shaft used is also an old one, built for the gasworks, but it is sufficiently large to serve the electricity works for some years. The space between the present boilers and the engine-room has been left for condensing plant. There is also plenty of room for an economiser, to be placed outside the boiler-house at the

Digitized by Google

base of the shaft. We must congratulate Mr. Middleton and his able assistant (Mr. R. J. Angel) on the transformation they have effected while successfully adapting the old means to the new end.

Steam Generating Plant.

The contract for the boilers was placed with Messrs. H. and T. Danks, Limited, of the Crown Boiler Works, Netherton. This firm has supplied two of their Lancashire type of boilers, which can be seen in the view of the boiler-house, Fig. 3. Each of these boilers is 7ft. 6in. diameter and 30ft. long, and contains two furnace tubes 3ft. diameter at the firing end and 2ft. 7in. at the other end. No cross-tubes were used, as it is contemplated that the canal water may be used sometimes, and then the cross-tubes would add to the difficulty of keeping the boilers clean. There are two longitudinal stays (Fig. 4), 2in. diameter, connecting the end plates, the screwed ends of the stays being swelled out and screwed 2¼in. diameter. These boilers are constructed to work at 160lb. pressure, and are fitted with a dead-weight safety-valve, a compound safety-valve, main steam-valves, blow-off cock, etc. These boilers and fittings were tested and passed by the Scottish Boiler Insurance Company, Limited. Two feed-pumps of the Worthington type are at present installed, each capable of feeding both boilers when working a maximum load. They are seen in position in Figs. 1 and 4, and are so connected that they can feed either from the exhaust-steam heater or direct to the boilers. The steam and feed pipes to these are arranged in duplicate to prevent all chance of a total breakdown. The town water is used for feed purposes at present, and is stored in the tank referred to above. It is contemplated that the canal water may be used, and a centrifugal pump, driven by a small Crompton motor, is placed in the tank-room for lifting the canal water up to the tank level.

The exhaust feed-heater is of the Brown-Berryman type, made by Messrs. Joseph Wright and Co., of Tipton.

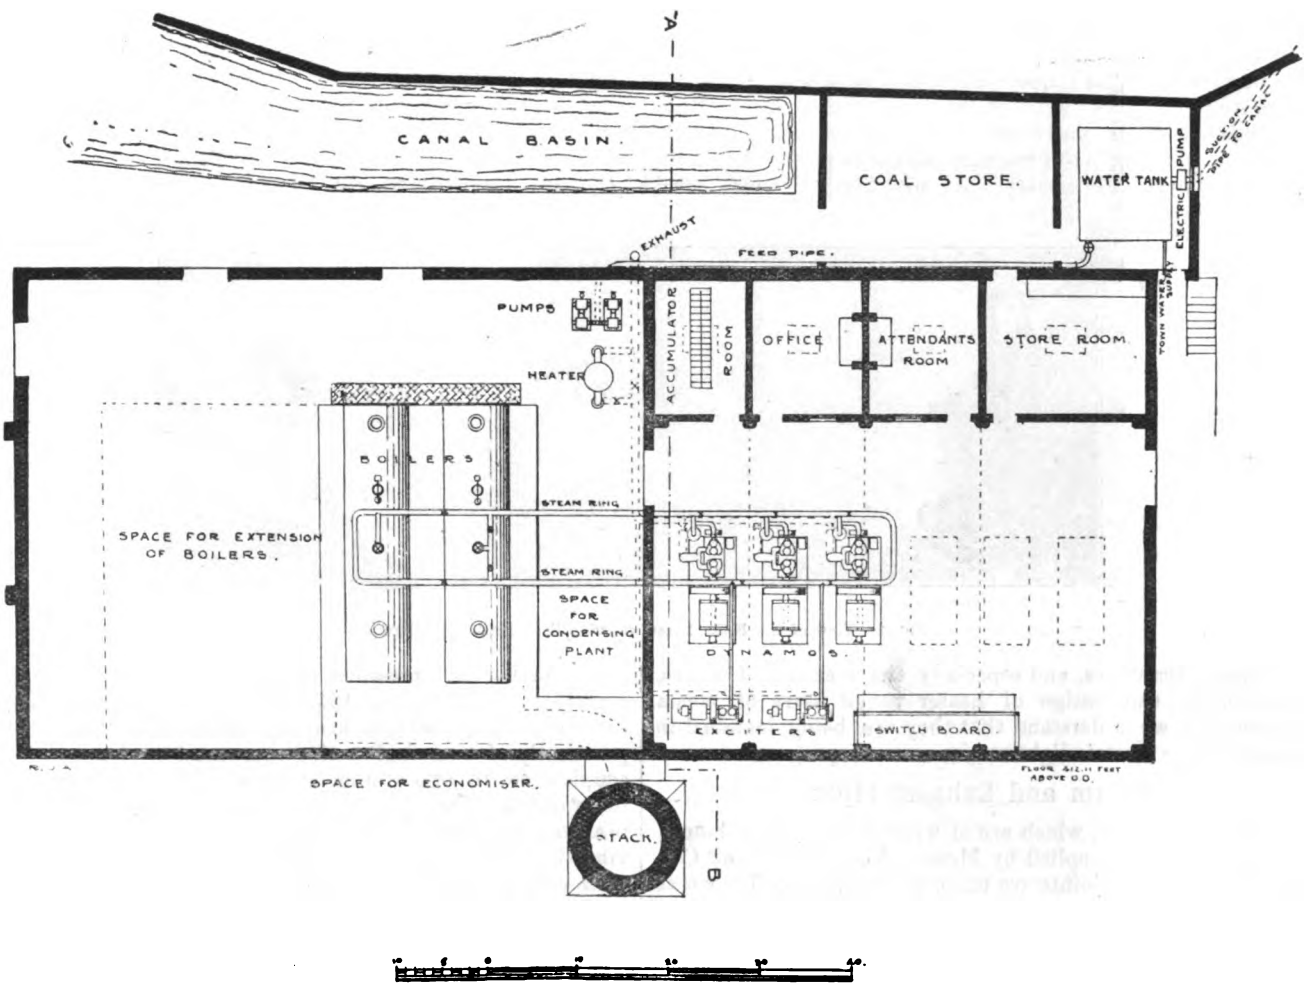


FIG. 1.—Plan of Walsall Electricity Works.

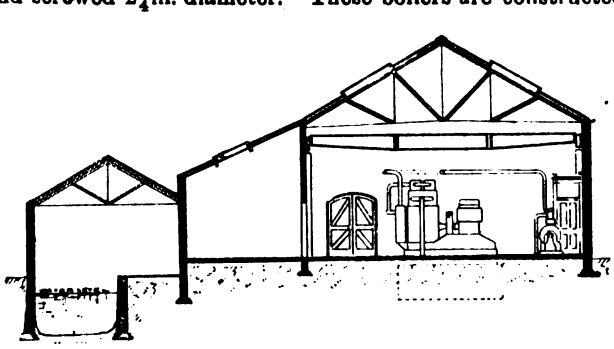

FIG. 2.—Sectional Elevation on the line A B.

The heater (Fig. 4A) contains several improvements brought out and patented by Mr. C. J. Brown which add to the general value of the heater. These exhaust steam feed-heaters require a considerable amount of cleaning if ordinary water is used for the feed, as the greater portion of the deposit is thrown down in them, instead of in the boilers, which saves the boilers considerably. The dirt and lime salts fall to the bottom of the heater and tend to accumulate round the tubes upon a horizontal tube-plate. Often starting from this accumulation, a formation of scale, hard or soft, according to the nature of the water, climbs up the tubes and destroys their efficiency for water heating when such horizontal tube-plates are used. To assist the easy removal of these deposits and incrustations, the above heater was designed by Mr. Brown. As will be seen by the section, the tubes are all fitted into a cylinder at the base of the heater, thus leaving the bottom clear, so that the deposit settles on the dished cover. This dished plate can easily be removed when cleaning is required, and thus afford clear access to the tubes. The annular space into which the ends of the tubes enter is divided into two halves. The steam from the exhaust-pipes then enters in one half, passes through the tubes to the other, and thence out to the atmosphere. The outer cast-

Digitized by Google

ing which bounds this space, and contains the inlet and outlet flanges, is so designed that it can be detached and lifted up over the body of the heater. This affords a ready access to the ends of the tubes should they need inspection or repacking. A mud-cock is fixed in the front in the usual way, from which the mud can be blown out two or three times a day. The tubes, which are of solid-drawn brass, are free to expand and contract with the varying temperature, being only held at the ends.

discharged into the atmosphere by the canal wharf shown in the ground plan.

Generating Plant.

The present plant (Fig. 5) consists of three 80-kilowatt Parker dynamos coupled direct to 120-h p. Bumsted and Chandler engines and two smaller exciting sets, also direct driven.

The engines of the larger sets are of the compound

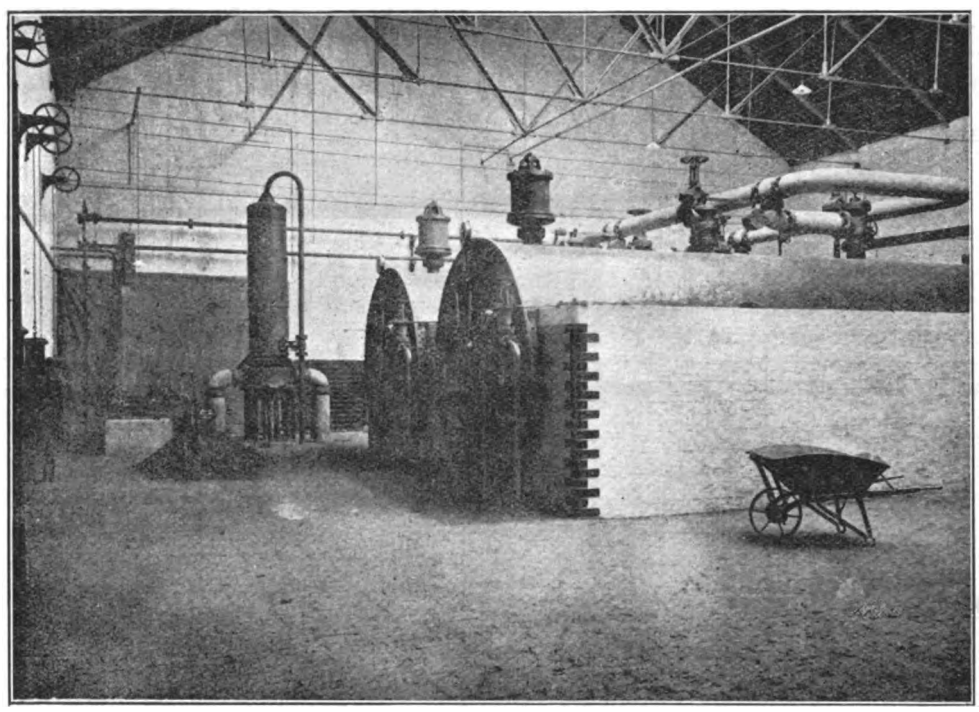

FIG. 3.—View of the Boiler-house, showing Feed Heater and Pumps.

These advantages, and especially the freedom of access, recommend this design of heater to all users of steam power, and we understand that they are being installed in many of the electric light stations now in progress.

Steam and Exhaust Pipes.

The steam-pipes, which are of wrought iron, with flanges welded on, were supplied by Messrs. John Russell and Co., of Walsall. The joints are made on the system known as the copper and asbestos combination joint. The ring

type, having low-pressure cylinders 15in. diameter and high-pressure cylinders 10½in. diameter. The speed of these engines is 350 revolutions per minute. They consist practically of two single-acting compound tandem engines, coupled on to two cranks at right angles. The moving parts in these Chandler engines are all in constant compression, and hence keep the engines free from knocks and vibration. The valve gears are arranged in cylinders at each end of the engine, the valves being of the piston type. The pistons, valve rods, glands, and stuffing boxes

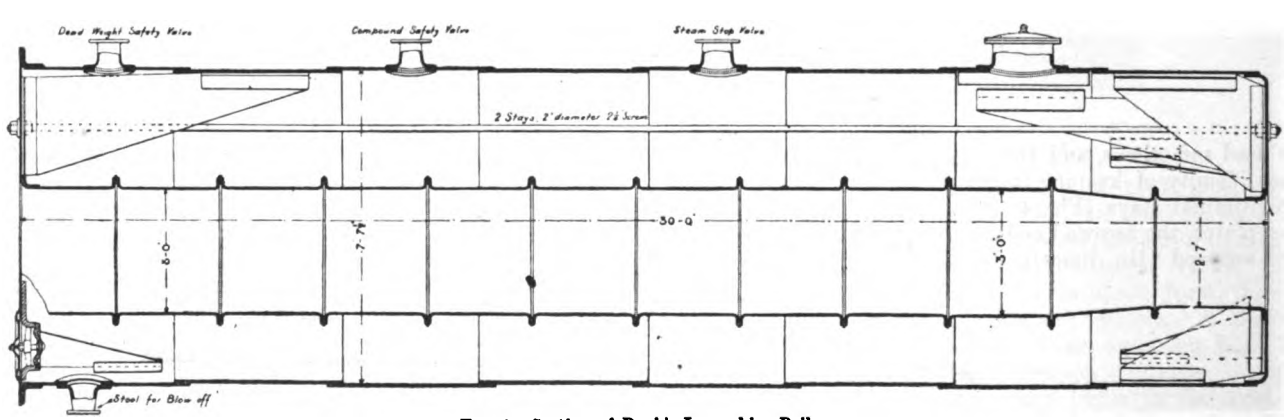

FIG. 4.—Section of Dank's Lancashire Boiler.

system of steam-pipes is used, and the general arrangement of the pipes, with the method of supporting, can be seen in Figs. 3 and 5. The ring extends directly over the boilers, which are connected one to each side of it. The whole of the valves are of Hopkinson's make. The pipes in the engine-room are supported on three vertical pillars, with rollers at the bearing surface to allow of lateral movement as the pipes expand.

The exhaust-pipes are of cast iron, and were supplied by Messrs. Lambert Bros., of Walsall. They are placed below the floor-level in spaces left round the foundations. The exhaust steam, after passing through the heater, is

under the cylinders of these engines are not subjected to steam pressure, and hence seldom require repacking, and the wearing of the brasses of the moving parts give little trouble. The engines are so designed that the crankshaft can be taken out from either end of the crank-chamber. Four covers are provided, two at each side, so that when all are taken off the working parts are most accessible. A good flywheel governor is attached to the outside end of shaft, which holds the engines well in hand. The variation of speed between no load and full load is only 2 per cent. The cranks dip into water and oil at every revolution, and hence are efficiently lubricated. Each engine is also fitted

Digitized by Google

with Winn's patent up-drop sight-feed lubricators of the latest type, having coil condensers. The two smaller engines used for the exciters are each of 15 h.p. The high-pressure cylinders are 4in. diameter, and the low-pressure 5¾in. diameter. These two engines run at a speed of 550 revolutions per minute. All these engines exhaust into the atmosphere at present, and run most satisfactorily.

The dynamos were all manufactured by Messrs. Thomas Parker, Limited. The 80-kilowatt two-pole machines (Figs. 6, 7, and 8) are designed to give 40 amperes at 2,000 volts when running at 350 revolutions per minute. They are drum wound with the patent Eickemeyer system, so largely used by Mr. Parker. This system is especially useful with high-voltage machines, as each section is wound separately on a former, and insulated before being put into position. The field magnets are of cast steel, the two limbs and yoke being one casting. This casting, however, terminates on the horizontal plane through the axis of the armature. The two other portions of the pole-pieces are separately attached to the brass supports, so that all the upper portions of the field magnets with the shunt windings can be lifted off, leaving the armature exposed *in situ*. The field magnets are separately excited by smaller dynamos provided for the purpose, or from a set of accumulators in the station should the small sets be standing. The high-tension terminals are shielded by plate glass, to prevent accidents by workmen touching them when attending to the machines. The commutator connections are made to the bottom of the cross-windings, so that the brushes are approximately horizontal. Three 1in. brushes are used at each pole to collect the current, and the machines when adjusted for lead run quite sparkless. The lubrication of these larger sets is carried out by means of a small pump, the plunger of which rests against an eccentric on the shaft. The oil in this case is delivered at the top of the bearing in through a sight-feed lubricator. These dynamos are mounted on the extensions of the engine bed-plates.

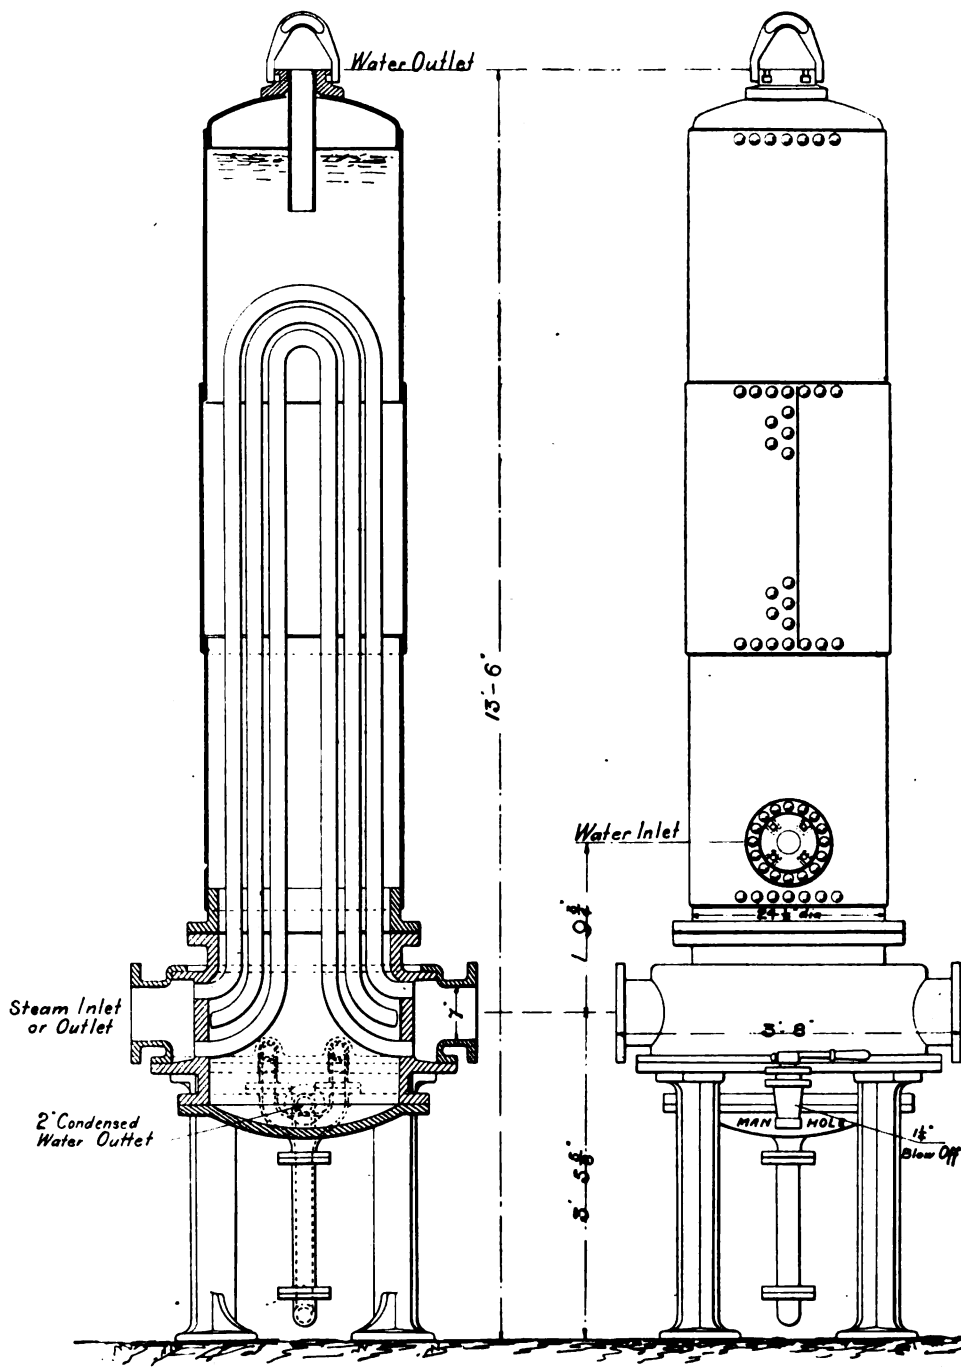

FIG. 4A.—Elevation and Section of the Brown-Berryman Heater

The two exciters are shunt wound, and each is capable of giving 60 amperes at 100 volts for exciting the large generators, or of working up to 135 volts for charging the accumulators in the station. These, too, have the Eickemeyer-wound armatures of the drum type and horizontal brushes. The lubrication of these machines is, however, effected by the ring method. A ring suspended on the shaft in the centre of the bearing drops into an oil-well in the pedestal, and as the shaft revolves carries the oil up to the bearing. These machines also supply the lights in the station, one of them being sufficiently powerful to excite all three of the large dynamos at the same time.

Digitized by Google

A battery of accumulators is provided in a room at the side of the engine-room. It consists of 57 cells of the Electrical Power Storage Company's K 11 type. This is used for lighting the station and supplying the exciting circuits when the exciters are not running. It has a capacity of 125 ampere-hours when discharging at a rate of 25 amperes.

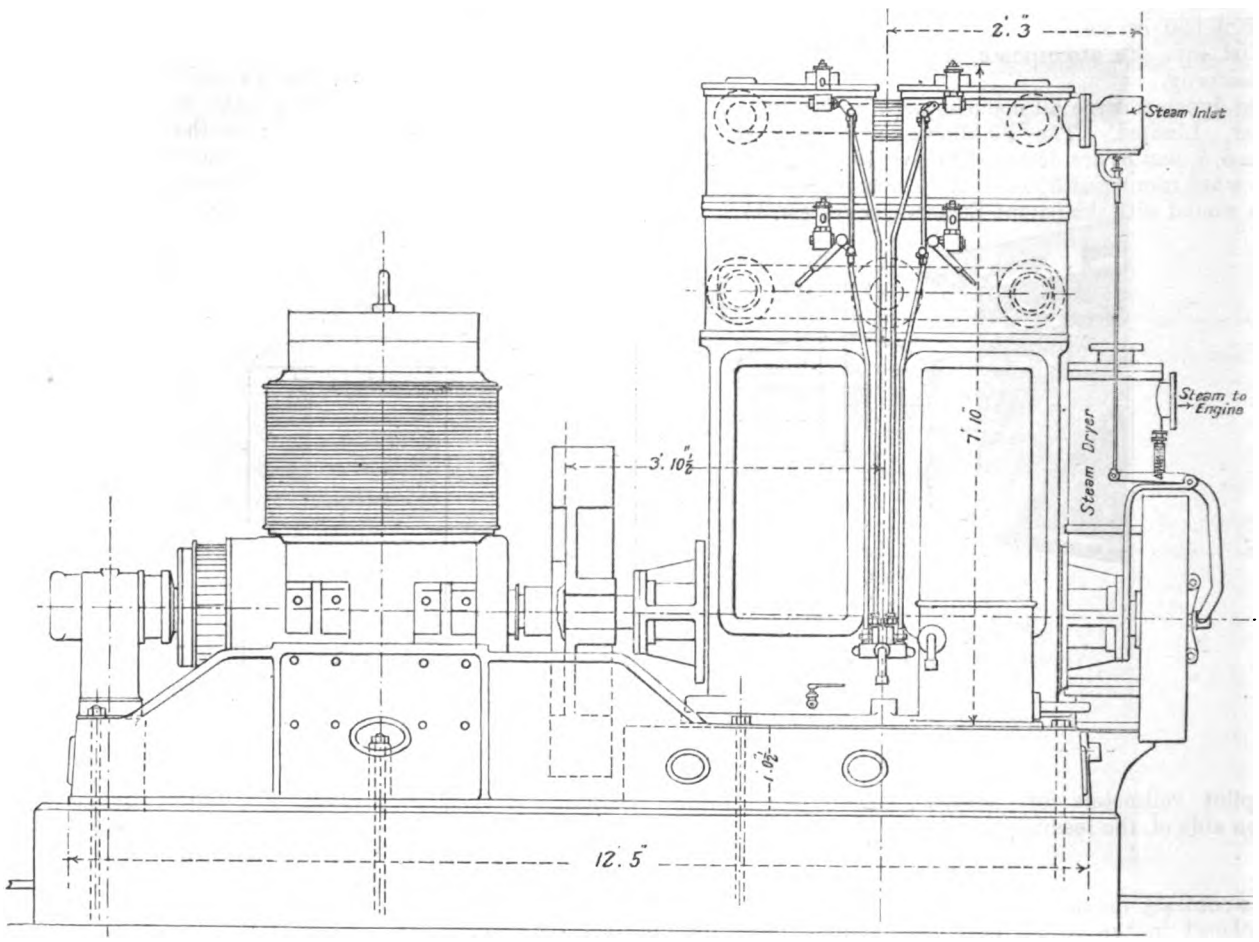

FIG. 6.—Elevation of the 80-K.W. Parker-Chandler Steam Dynamo.

Switchboard.

The switchboard (Fig. 9) consists of 10 panels of unpolished slate mounted on substantial wood backings, and, in addition, six low-tension voltmeters are mounted on a wood boarding above. Of these panels there are three generator panels, each fitted with an ammeter for measuring the currents generated by the three dynamos; one double-pole automatic magnetic cut-out and main switch (the automatic cut-out on the main switch is set to break circuit should the current rise to twice the normal full load—*i.e.*, 80 amperes); one 17-way field-regulating switch; one ammeter for field circuit; and one switch for opening the field-magnet circuit and short-circuiting the same on itself. This switch is of the throw-over type, so designed that the field winding is short-circuited directly the connection to the exciting E.M.F. is broken.

Two exciter panels, each fitted with one ammeter for showing the output of the exciters, two double-pole switches and fuses for connecting exciters to the 'bus bars or to the accumulators, and one nine-way shunt-regulating switch.

One battery panel, fitted with one ammeter for measuring the charging or discharging current, two double-pole switches and fuses for connecting the battery to either the dynamo charging bars or to the station lights and exciting circuit, and one six-way regulating switch for varying the number of cells in circuit.

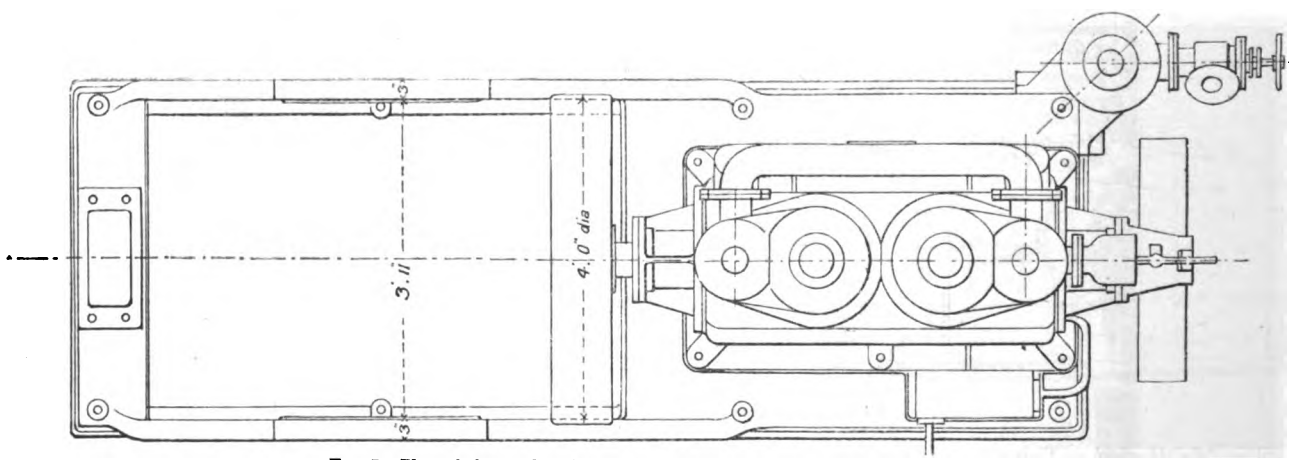

FIG. 7.—Plan of the 120-h.p. Bumsted-Chandler Engine and Extended Bedplate.

One voltmeter panel, containing two "Kelvin" voltmeters, each reading up to 2,100 volts, one being connected across the main 'bus bars and the other to a three-way double-pole plug switch for paralleling generators.

Three transformer feeder panels, each fitted with one ammeter, one double-pole automatic magnetic cut-out and main switch (the magnetic cut-out breaks the circuit in case a shunt occurs on the feeders); one 33-way transformer starting and regulating switch; single-pole switch

Digitized by Google

for short-circuiting pilot wires. Resistances are provided for starting and regulating each of the transformers, and these are connected up to 33-way switches.

The voltmeters above the slate panels are used as follow: two for the exciters, one for the batteries, and three large-dial pilot voltmeters for indicating the E.M.F. at low-tension side of the feeding points.

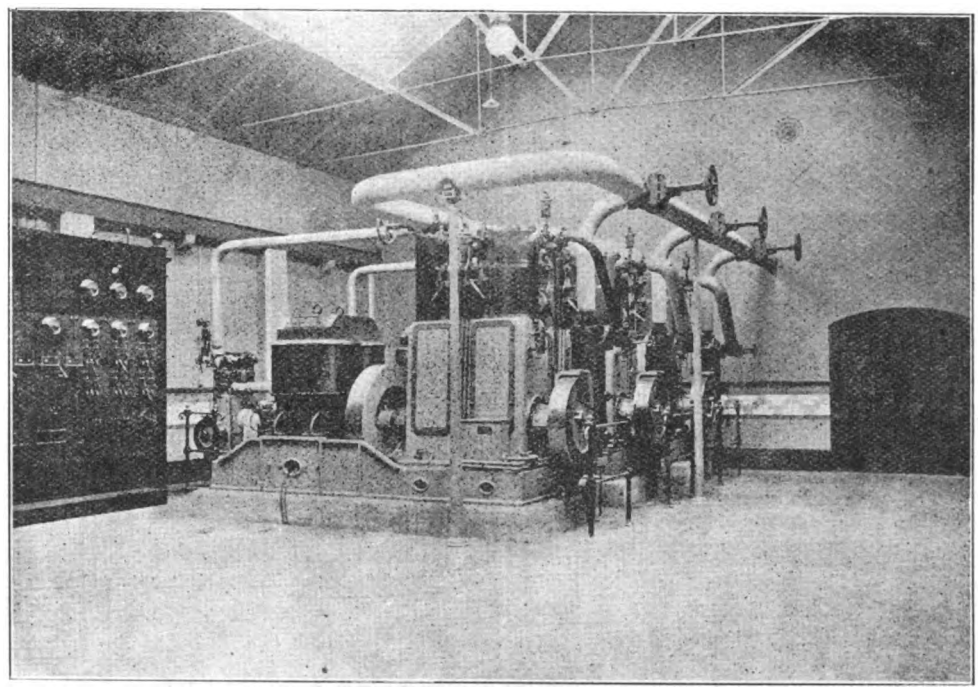

FIG. 5.—General View of Engine-Room.

Mains.

The contract for the whole of the underground mains was placed in the hands of Callender's Bitumen Telegraph and Waterproof Company, Limited, and the whole work has been carried out by them under the charge of their resident engineer, Mr. A. Burton. The Callender Company have not only supplied the cables and laid them, but have carried out all the street work, excavation, and permanent reinstatement. The supply is by continuous current, generated at a pressure of about 2,000 volts at the electric lighting station in the gasworks yard (Fig. 10), and distributed thence by concentric vulcanised indiarubber cables drawn into cast-iron pipes to three sub-stations, which are placed at convenient points in the town. These are shown by black circles in the plan, and are situated as follow: No. 1, in basement of a shop at junction of Stafford-street and Park-street; No. 2, in basement of St. George's Hall in Darwell-street; No. 3, in basement of Assembly Rooms in Goodall-street. The section of the feeder cables used is in each case $^{19}/_{16}$.

From the electric light station to the point where the mains branch off to the first sub-station—*i.e.*, at the corner of Stafford-street—the feeder-pipes are two in number, each having a diameter of 4in. From thence two 3in. pipes lead to the bridge, and from there one of the 3in. pipes is taken to each sub-station. The approximate distances from the generating station to the sub-stations are as follow: to No. 1, 700 yards; to No. 2, 1,090 yards; to No. 3, 1,285 yards; and the total length of feeding cable which has at present been drawn in is about 3,100 yards. In addition to these, a

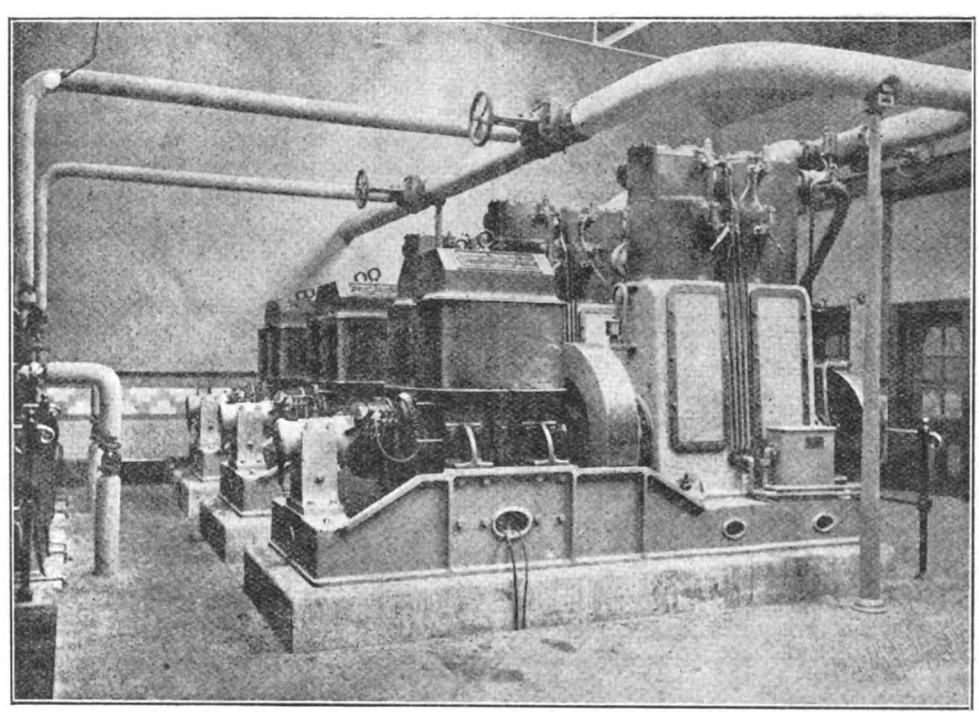

FIG. 8.—View from the Switchboard of the Three Large Steam Dynamos.

Digitized by Google

separate 2in. cast-iron pipe is laid concurrently with the high-pressure concentric pipes, and contains for each sub-station two single-conductor pilot wires, each No. $^{7}/_{22}$, and a two-core telephone cable, each conductor being $^{3}/_{22}$.

(Fig. 10), have been constructed on the pipe lines with blue Staffordshire bricks set in cement 9in. work. They are provided with Callender's well-known type of double lid, each lid being set separately and distinct from the other,

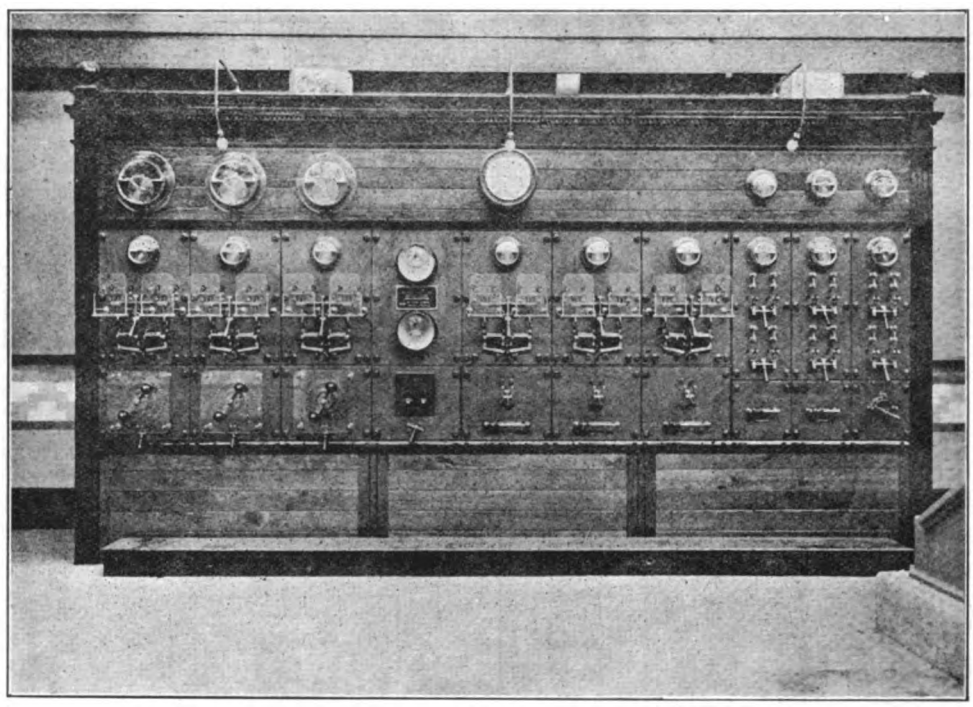

FIG. 9.—The Walsall Switchboard.

These go from the generating station to each of the sub-stations. About 7,200 yards of single-conductor pilot cable and about 2,500 yards of two-core telephone cable have been used. The cast-iron pipes are Post Office specifi-

so that in the event of any accident to the mains the outer lid will not become electrically charged. The inner lid is thoroughly earthed, being in metallic connection with the pipe lines. Each section of pipe line is also in metallic

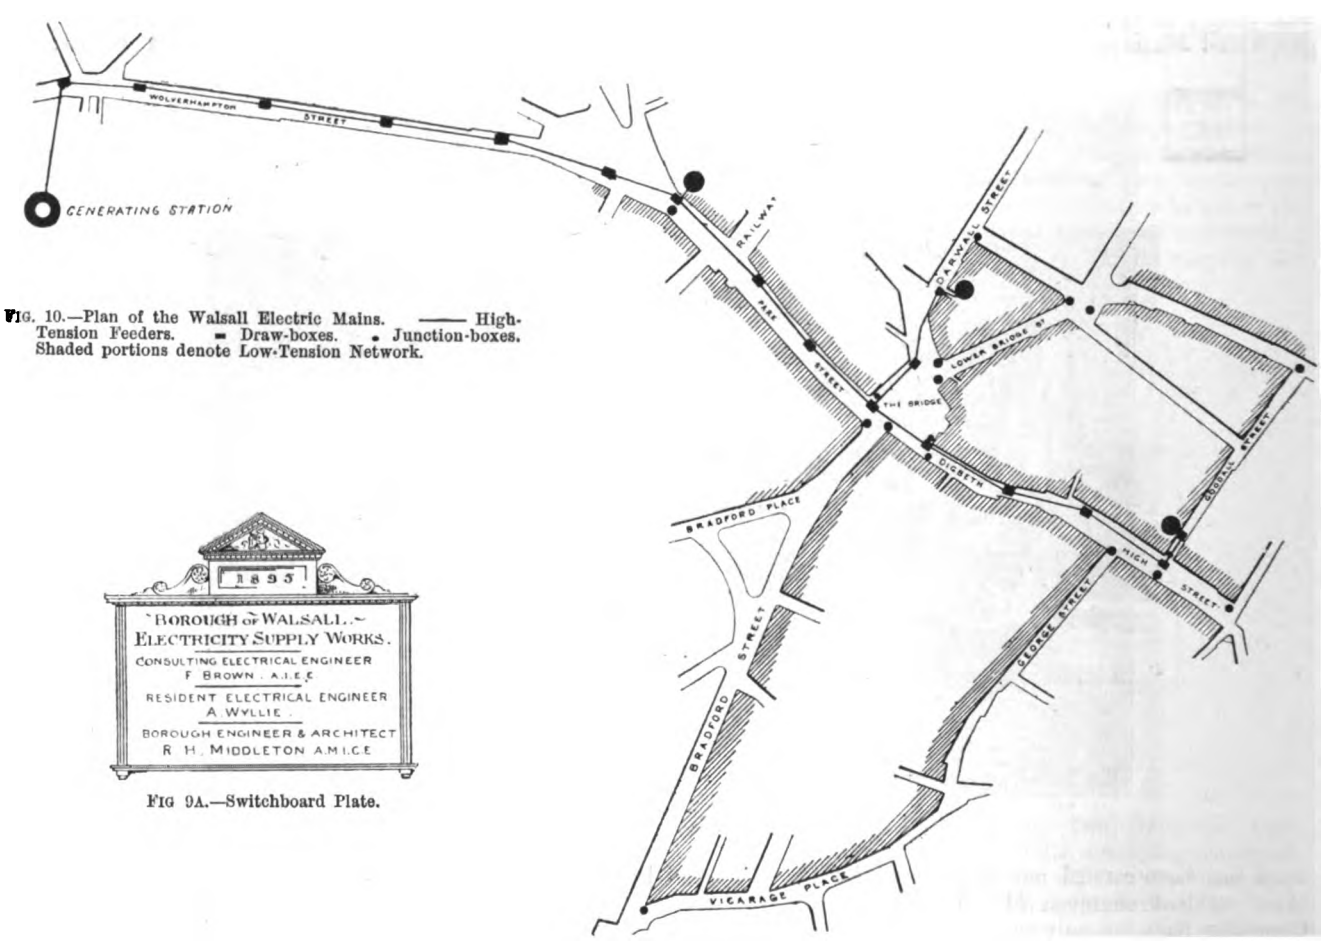

FIG. 10.—Plan of the Walsall Electric Mains. —— High-Tension Feeders. ▪ Draw-boxes. • Junction-boxes. Shaded portions denote Low-Tension Network.

cation, coated out and inside with Dr. Angus Smith's solution. Their joints are all carefully made with blue lead and yarn.

The draw-boxes, shown by black rectangles in the plan

connection with the next by means of strands of copper wire. There are 18 boxes on this pipe line, of which 11 are 24in. by 24in. on the heavy line, and seven are 20in. by 20in. on the single-pipe lines. The depth of the boxes

Digitized by Google

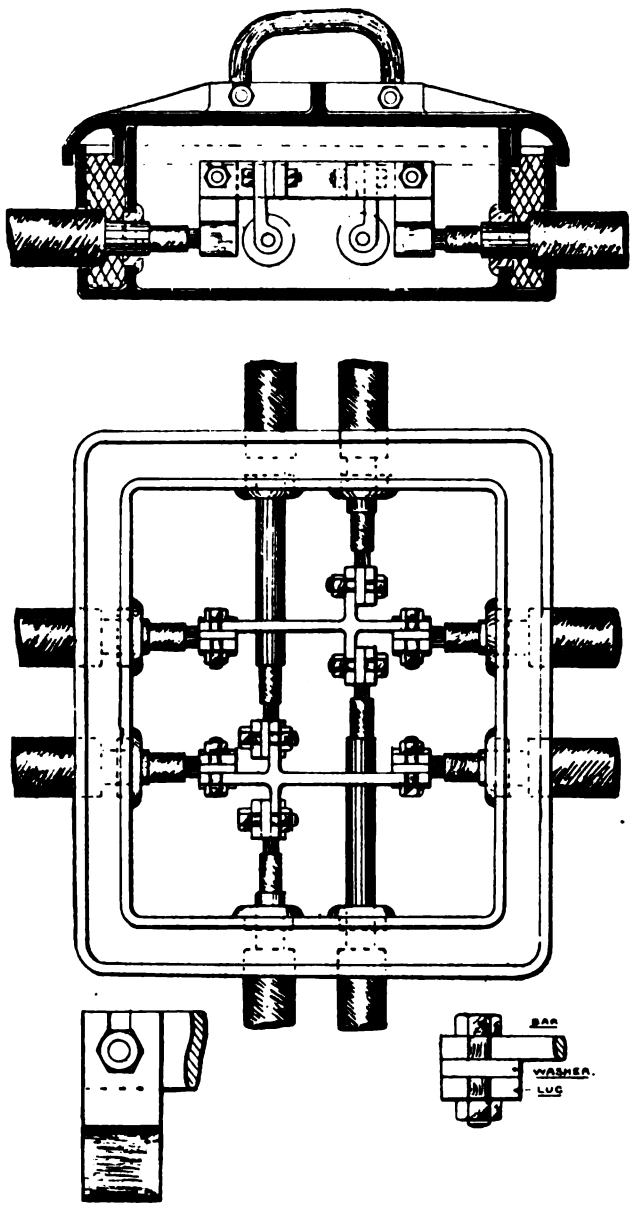

FIG. 11.—Callender's Network Box.

From each sub-station a network of low-pressure cable is carried through the principal streets of the town, and distribution is made on the two-wire system. The network consists of single-conductor, lead-sheathed, and steel-armoured cables of Callender's well-known type laid two side by side. The section of these mains is ·54 square inch in the busy streets and ·25 in those of lesser importance. About 1,600 yards of ·54 main have been laid and 2,500 yards of ·25, so that double that amount of cable has been used.

The streets in which the network is at present laid are as follow: Park-street, Digbeth-street, St. Paul's-street, Bridge-street, Leicester-street, Vicarage-place, The Bridge, High-street, Darwell-street, Goodall-street, George-street, Bradford-street.

Network boxes (Fig. 11) of Messrs. Callender's standard type, have been placed at the corners of all the important streets where the distributors are placed, and at present there are 17 of them. Fig. 12 shows the process of fixing on of these and the facility with which they are connected to the cables. Each of these boxes is placed in a pit built of blue bricks set in cement, and provided with cast-iron frame and concrete-faced surface cover. Consumers are connected with the mains by means of cast-iron service boxes, buried in the ground without any pit or other protection in the same way as gas services

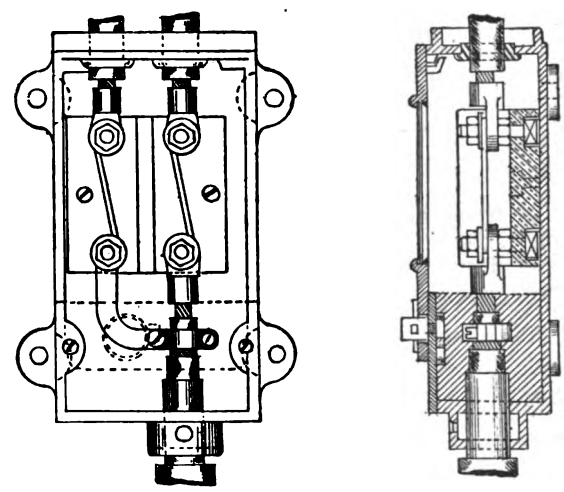

FIG. 13.—Reid's House Connection and Fuse Box.

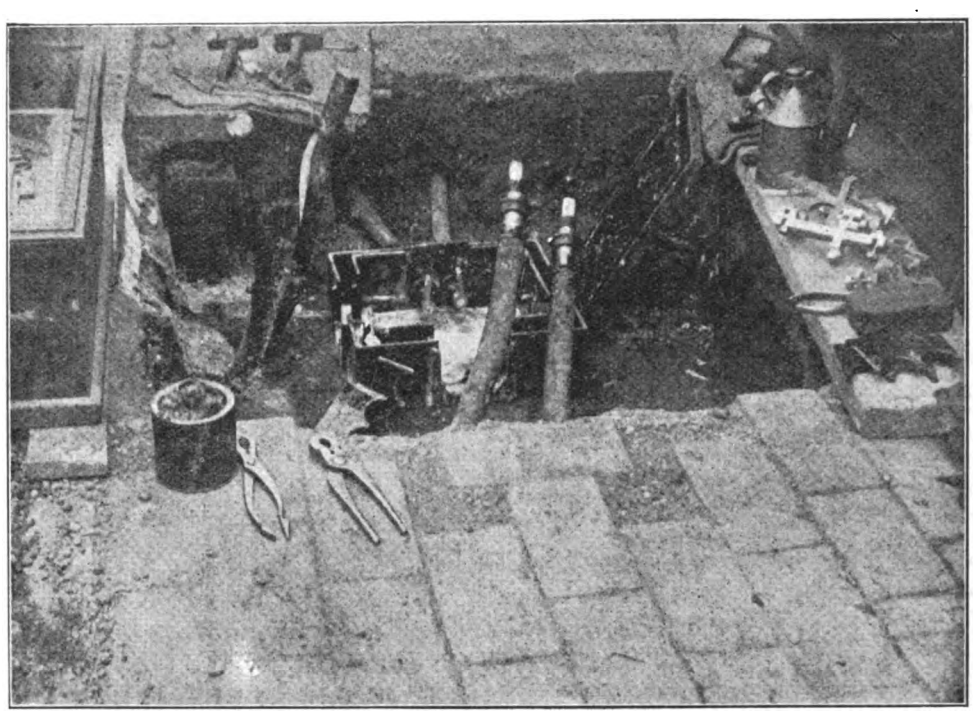

FIG. 12.—View of a Junction Box in Course of Fixing.

varies, as the pipes have been laid to give a fall into each box, and it has therefore been necessary to excavate somewhat deeper than was expected. Some of the boxes, in consequence, are fully 7ft. deep.

are connected. There are at present over 40 consumers thus joined up, and more are probably being added.

THE INSTITUTION.

According to the report of the meeting last week, some of the members were on the warpath. It is somewhat difficult to know the cause of the storm, or to find out the goal of those adverse to the Council. The first thing to remember is that for this year the Council has been elected, and however much individual members may object to men on that Council, bygones must be bygones. If objection is to be made, it must be directed towards next year's house list. We admire the plucky way in which the hostility to the Council was shown, although we do not think the hostility was correctly directed. There seems to be a series of distinctions, too fine drawn to impress us with their value. Thus, men are suitable as ordinary members, but not as members of Council; they are all right as members of Council, but not as vice-presidents; they are all right as vice-presidents, but not as president. Now, we are not going to summarise the leading points put forward by the contestants—there is plenty of time for that—but we do want a categorical statement from the objectors of their objections. The Institution is an incorporated society, governed by legal articles. Have these articles been carefully read? Do the members know the rules and regulations under which they are governed? If not, we would suggest as the first act of the new Council that it issues a number of the *Journal* giving these details. The ordinary members will then see what their rights are under the articles and what their wrongs. They will see how far, under these articles, they are powerful to elect the members of the Council. It is useless asking for this and for that if the request be contrary to the articles, but it is very tantalising when members get up to air just complaints to find by these unknown articles they are out of court. It may be well at once to say that in our estimation a committee such as that hastily proposed at the last meeting is unworkable and unwarranted by the condition of the Institution. Destructive criticism is easy enough. Anybody can become an iconoclast. That is not what is wanted, but rather constructive criticism to tell us what to do when a vacant space is created by knocking down some existing institution. An idea seems to underlie recent criticisms that the Council is elected to formulate courses of action, bring the formulæ to the notice of the members, or some of them, and, if sanctioned, to proceed in the action. If that idea exists, the sooner it is got rid of the better. The Council is a body of men elected by the members to carry on the ordinary work of the Institution without worrying members over every petty detail of daily routine. It is supposed to consist of capable representative men who have the welfare of the Institution at heart, and who will be always ready to sink the interests of self in the interests of the Institution. Every section of the members is by the ideal Council to have a representative, but we know how difficult it is to find the ideal in the real. However, discussion on these and other points may be left for a few weeks; let us first know where we stand, and this can only be done by knowing the articles under which we are governed. Will the Council consider the suggestion

Digitized by Google

and issue the articles before the general meeting promised last week to discuss the differences between Council and members is called?

FIRES AND ELECTRIC LIGHTING.

We are glad that Major Flood Page has again called attention to this subject through the columns of the *Times*. It is a subject of the utmost interest, and should therefore be approached without prejudice. We fear Major Flood Page has made out too favourable a case for electric lighting. His statistics are really statistics of facts, but the facts are not of the kind to allow of too broad a generalisation. In the first place, the number of electrical installations, gas, and oil burners in competition are unknown. If we could have the number of electric lamps, the number of gas burners, the number of oil lamps, and the number of candles in use, we might then get the percentage of fires arising from each source, but to say there was only one fire from electricity and one hundred and seventy-five from candles in 1892 is somewhat misleading as regards correct conclusions. It may be that the percentage of fires arising from candles is less than the percentage arising from electricity. We do not for a moment believe that it is so, but we cannot from the figures given by Major Flood Page prove that it is not so. It is to be regretted that Major Flood Page has thought fit to resuscitate controversy on the pressure question. Every electrical engineer, every municipality, everyone, in fact, interested in the question, had full liberty to put his views forward at the recent conference, and surely, after that conference, we might have been held safe from further criticism. What was the use of the conference if the thing is to be discussed in the newspapers? The householders will naturally take hold of these differences of opinion and ask, who is right? You cannot explain to the ordinary householder that so far as the old wiring is concerned the section is more than ample to carry the lesser current without heating; in fact, that so far as the conductor is concerned, the danger is lessened by the increased voltage, and that any increase of danger will arise from defective insulation and arcing. It may be that the existing fuses will be sufficiently sensitive under the new conditions, but if doubt arises they can be changed with little trouble or expense. All the new wiring will bear the same relation to the new conditions as the old does to the old conditions. All these details, however, are questions for experts, not for the general public; and as the experts in solemn conclave have advocated the change, we must again say that Major Flood Page's remarks are a little out of place in being put before non-technical readers.

Magnetic Surgery.—The extraction of steel particles from the eye is a subject which has especial interest for Sheffielders. It seems that since Mr. Snell's appointment to take charge of the eye department in 1877 no magnets or electromagnets have been used at the Sheffield General Infirmary except those devised by him. Since then Mr. Snell's numerous papers on the removal of small steel fragments from the eye, and his volume on the subject, have secured for the instrument literally a world-wide repute.

WALSALL ELECTRICITY WORKS.

(Concluded from page 709.)

These network boxes are shown by small black circles on the plan (Fig. 10), and the side of the streets now served by low-tension cables are shaded. The service cable used is single-conductor lead-sheathed and armoured similar to the mains used in the streets, except that it has a smaller section. This runs from the mains direct into the consumers' premises, where it terminates in one of Reid's patent cut-out boxes (Fig. 13). This box acts not only as a cut-out, but as a permanent seal for the cable end, preventing any injury to the cable even in damp cellars.

Great care was taken in the laying and jointing of these cables, as may be gathered from the fact that the whole network tested over 400 megohms when completed, although the specified limit was 50 megohms. At the same test, no deflection was found when testing all these feeders in parallel, hence showing infinite resistance.

Sub-Station Outfit.

There are three sub-stations, the principal one being at the St. George's Hall, where the battery is fixed. In each of these there is at present one motor-generator. These transform down the high tension supplied by the feeders, and have an output at the secondary terminals of 105 volts, 400 amperes, when supplied with primary current at 1,950 volts. They run at a speed of about 550 revolutions per minute, but the transforming ratio is independent of the speed. Fig. 14 shows two views of these machines, which have the Parker patent hinged poles to allow the armature to be removed by lifting directly upwards. The field magnets, which are of cast steel, have two windings, the one being in series with the primary high-tension armature, and the other as a "shunt" across the low-tension armature. The series winding is only used in starting, and is designed to reduce the starting current to a value at least half of that required by the similar continuous-current transformers at Oxford. It is short-circuited as soon as the voltage on the secondary or low-tension armature rises above 80 volts. The removal of the resistance of the series-turns is also a great advantage, as it gives a much more constant regulation at varying loads. The bearings are fitted with automatic lubricating pumps, in addition to rings, which also give continuous lubrication. The pumps, which are worked by eccentrics on the shafts, are connected on the delivery side to the under part of the bearings.

The other parts of each sub-station outfit consist of one long-range switch for closing the secondary circuit from the transformer to the network. It is operated from the central station, the magnet coils being wound with wire in series with the pilot wires. Combined with this switch there is an automatic magnetic cut-out, which breaks the circuit in the event of too great current being demanded, or in event of the current coming back from the network, due to the transformer for any reason failing to give its proper E.M.F. The details of this switch are shown in Fig. 15. E is the cup-shaped electromagnet, the armature being in the attracted position. R is the rachet wheel, which on alternate strokes puts the low-tension switch, S, on and off; it is moved by the pawl, P, on the armature frame. M is the magnetic cut-off, which releases the switchbar, C, should the current rise abnormally.

One series field short-circuiting switch is also supplied with each main transformer. It consists simply of a horseshoe magnet wound with wire in series with the shunt circuit of the transformer. When the current rises to a point equivalent to 80 volts, the armature is attracted, and the switch short-circuits the series winding on the transformer magnets.

Besides these two switches there is additional plant connected with the accumulators at the main sub-station at St. George's Hall. This main battery consists of 114 cells in lead boxes, manufactured by the Electrical Power Storage Company, each containing 50 K, or high-discharge plates. These cells are capable of discharging at 150 amperes for five hours, or, in cases of emergency, this rate can be easily doubled for short periods. The cells are contained in lead boxes (Fig. 16), and each consist of two

Digitized by Google

parallel sections of 25 plates. They are connected in two sets of 57 cells each, and then connected in parallel, if desired, at the switchboard.

regulated by means of a resistance in the primary circuit. The battery switchboard is a slate panel fitted with two ammeters, one for each battery; two voltmeters; two

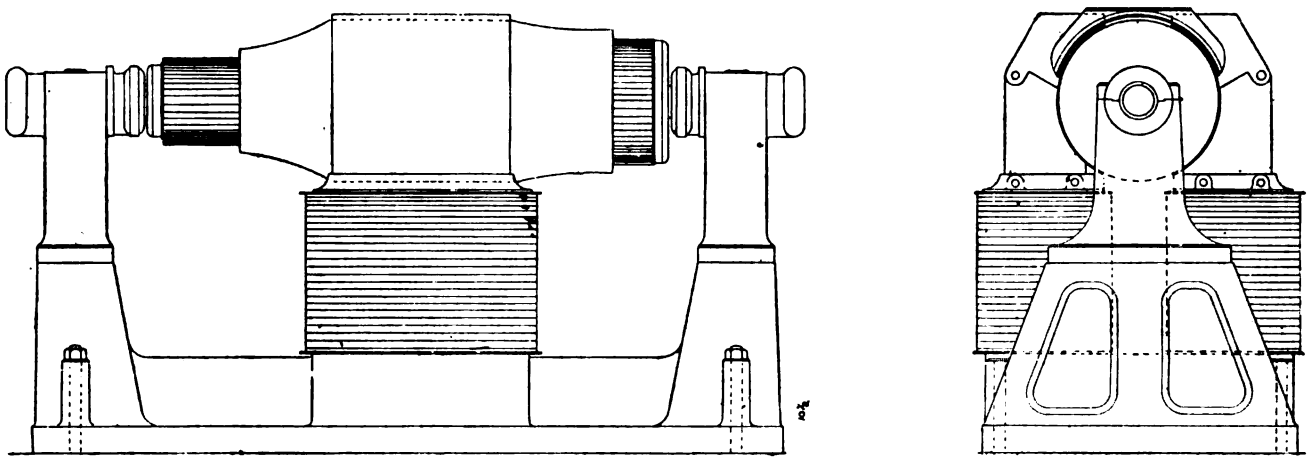

FIG. 14.—Motor Generator Transforming from 2,000 Volts to 105 Volts.

A battery-charging transformer, or booster, is also fixed at the central sub-station. It takes its primary current at 105 volts from the distributing network, giving an output

throw-over switches for putting batteries to charge or discharge; two switches for taking the batteries out of circuit or for switching them on; two double-pole fuses;

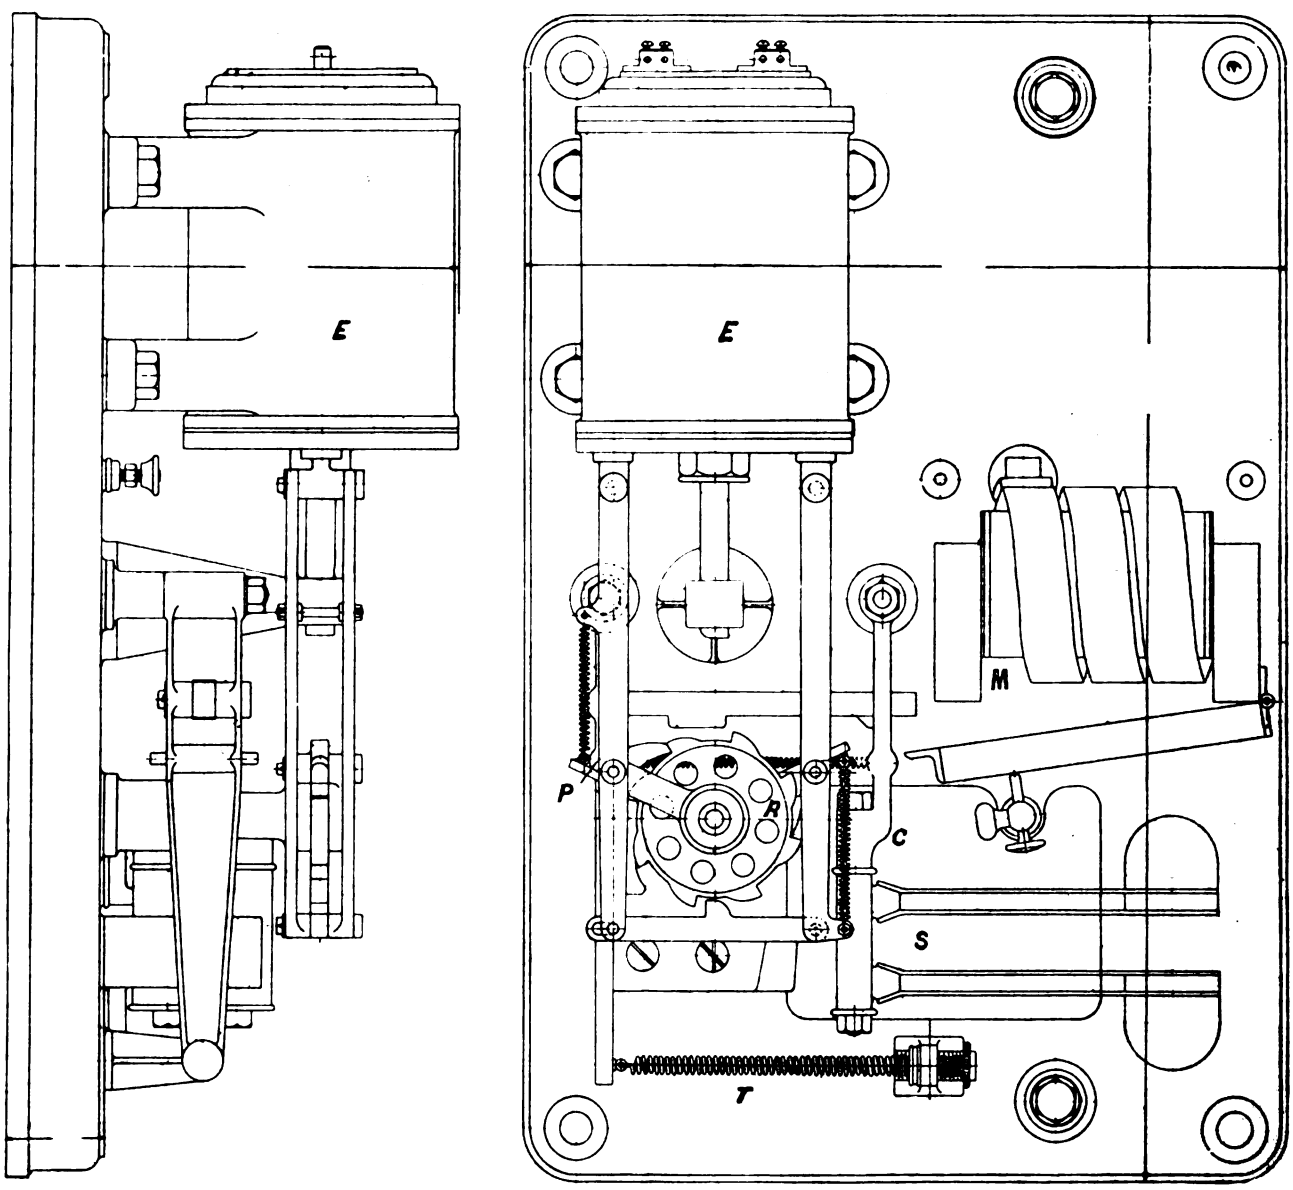

FIG. 15.—Plan and Elevation of Parker's Magnetic Long Range Switch.

at the secondary of 300 amperes at 35 volts; this being connected in series with the distributing network, makes a total of 140 volts for charging. The E.M.F. is

two six-way battery-regulating switches, to vary the cells in use; and one transformer starting and regulating switch.

Method of Working.

The generators are excited in the usual manner from the exciters or battery, and are run in parallel, feeding on the main omnibus bars. From this the feeder circuits take their supply through the double-pole cut-outs, and feed the transformer sub-stations. The battery is always on the network when the transformers are not running, and they maintain the proper E.M.F. on the mains at light loads. To start the transformer, the main feeder switch at central station is put on, the starting switch being turned so that all the resistance is in series with the high-tension armature and the series winding on the magnets of transformer at the distant sub-station.

The resistances are so adjusted that with 2,000 volts on the 'bus bars about seven amperes will pass through the circuit. This starts the transformer, and as it gains in speed the shunt circuit of the transformer connected across the secondary armature becomes energised. The current passes round the magnet of the series field short-circuiting switch, and energises this. It then draws the armature up, and short-circuits the series coils, leaving the shunt only to energise the transformer magnets. When this has occurred, it can be seen by the man in charge of the switchboard at the central station, as by watching the ammeter he sees the current going down as the transformer gets up speed. The 33-way switch is then turned round so as take out the starting resistance. The single-pole switch at the central station is then closed, thus short-circuiting the voltmeter on the pilot wires. This causes sufficient current to pass round the magnet of the long-range switch for it to attracts its armature, and so close the circuit from the secondary of the transformer to the distributing network. The regulation of the E.M.F. of the system is controlled from the central station by increasing the E.M.F. of the generators as the load comes on to allow for the drop in feeders and transformers.

Extra means for regulation of any differences there may be between the various transformers is carried out by inserting a resistance in the feeder circuits, this being put in or out as required by means of 33-way switches. To take transformer off circuit the reverse process is carried out, the secondary circuit being first opened by short-circuiting the pilot wires, and so operating the long-range switch. In event of one of the cut-outs on the secondary of the transformers opening the circuit, the long-range switch is left in a position that it can again be closed from the central station exactly in the same manner as when putting on circuit in the usual way.

The whole system is carried out under the patents of Parker, Woodward, and Rees.

The prospects of the undertaking are exceedingly good, as the equivalent of over 3,500 8-c.p. lamps are now connected and being regularly supplied. The orders actually in hand show that a load of over 5,000 may be expected before the end of the winter. The station engineer is Mr. Alex. Wyllie, who, after experience of the similar system at Oxford, joined the staff, and has assisted Mr. Brown in the supervision of the work in course of construction. The charges authorised by the Council for electric energy is 6d. per Board of Trade unit for lighting purposes, and 4d. per unit for motors. The motor load is expected to be a valuable item in the revenue, as five motors are already at work. The energetic chairman of the Electric Lighting Committee (Mr. T. Brownhill) has throughout shown great personal interest in the undertaking, and has received every support from the Mayor (Mr. Joseph Noake, J.P.)

FIG. 16.—View of the Main Batteries in the Chief Sub-Station.

The following is the approximate cost of the various parts of the present plant:

Buildings	£2,058
Engines	1,582
Dynamos, switchboards, transformers, and accumulators	5,600
Boilers	834
Mains	4,845
Pumps, feed, heater, steam and exhaust pipes, etc.	875
	£15,794

The total amount allowed to be borrowed by the Local Government Board was £22,000, so that the funds have not been exhausted.

THE INSTITUTION DINNER.

The annual dinner of the Institution of Electrical Engineers was held on Friday, the 13th inst., at the Freemasons' Tavern, Great Queen-street. Mr. R. E. Crompton, the President, was in the chair, and about 250 of the members and their friends were present. The guest of the evening was H.R.H. the Duke of Cambridge, K.G., K.T., K.P., and the guests included, amongst others, Lord Claud Hamilton (chairman of the Great Eastern Railway Company), Mr. J. Wolfe Barry (vice-president of the Institution of Civil Engineers), Sir J. Crichton-Browne, F.R.S. (treasurer,

Royal Institution), Colonel A. C. FitzGeorge (equerry-in-waiting to H.R.H. the Duke of Cambridge), Sir Thomas Blomefield, Bart. (Board of Trade), Dr. A. G. Vernon Harcourt, F.R.S. (president, Chemical Society), Mr. H. Edmunds (president, Northern Society of Electrical Engineers), General Markham, R.A. (Director-General of Artillery), Mr. C. G. Mott (chairman, City and South London Electric Railway), Colonel Sir John Ardagh, K.C.I.E. (commandant, S.M.E., Chatham), Colonel W. de W. Abney, R.E., C.B., F.R.S. (president, Physical Society), Mr. John Bell (chairman, Metropolitan Railway). The following gentlemen were also present:

Sir F. Abel, Mr. H. G. Allen, Mr. R. W. Allen, Mr. W. H. Allen, Mr. Amy, Mr. Anning, Mr. Anson, Mr. E. Ashton, Mr. Ashton, Mr. Aubert, Prof. Ayrton, Major Bagnold, Mr. F. Bailey, Mr. Barley, Mr. Bathurst, Mr. Beadle, Mr. Beaumont, Mr. Belshaw, Mr. Benedict, Mr. H. Bennett, Mr. A. Bergtheil, Mr. Bevis, Mr. Billington, Colonel Bingham, Mr. G. Binswanger, Mr. M. Binswanger, Mr. Birt, Mr. Black, Mr. Boot, Mr. Brett, Mr. Briault, Mr. E. J. Bristow, Mr. G. L. Bristow, Mr. Brockman, Sir W. R. Brooke, Major Cardew, Mr. E. Cardin, Mr. J. Cardin, Mr. Carpmael, Mr. W. A. Chamen, Mr. C. T. D. Chamen, Mr. Von Chauvin, Mr. Cheesman, Mr. W. Clark, Mr. Latimer Clark, Mr. Cluer, Mr. Coles, Mr. Colvin, Mr. Comport, Mr. Cooke, Captain Creak, Mr. Cree, Mr. R. S. Crompton, Mr. Crookes, Mr. Crowe, Mr. Curra, Mr. Dale, Mr. D'Alton, Mr. W. H. Davies, Mr. E. F. Davies, Mr. Dearlove, Mr. Devonshire, Mr. Doherty, Mr. Donnie, Mr. Down, Mr. Dowsing, Mr. J. E. Dowson, Mr. W. Dowson, Mr. Drake, Mr. Drysdale, Mr. Duddell, Mr. Eden, Alderman Ellis, Viscount Emlyn, Mr. Epstein, Mr. Erskine, Mr. Esmond, Mr. Esson, Mr. Evans, Mr. Fairfax, Mr. Ferranti, Mr. Ffinch, Mr. Fisher, Mr. Fleetwood, Prof. Forbes, Mr. Ford, Mr. H. B. Forde, Mr. Francis, Mr. Gabbett, Mr. de Calindez, Mr. Garcke, Mr. Gavey, Mr. G. Gibson, Mr. J. Gibson, Mr. A. Gordon-Smith, Mr. J. Reeves, Mr. Reid, Mr. Reynolds, Mr. Roberts, Mr. Robinson, Mr. Rosenthal, Mr. Samuelson, Mr. Seymour, Mr. Shackleford, Sir E. M. Shaw, Mr. Sherrin, Mr. Short, Mr. Dane Sinclair, Mr. F. Smith, Mr. H. W. Smith, Mr. R. A. Smith, Mr. Snell, Mr. Spagnoletti, Mr. C. P. Sparks, Mr. E. L. Sparks, Mr. H. C. Sparks, Mr. Spilsburg, Mr. Stearn, Mr. Stevens, Mr. Stewart, Captain Stiffe, Mr. Still, Mr. Stothert, Mr. Stottner, Mr. Stroh, Captain Stuart, Mr. Stuart, Mr. C. Swan, Mr. J. W. Swan, Mr. Swinburne, Mr. Swinton, Mr. Taylor, Prof. S. P. Thompson, Mr. Tree, Mr. Trezise, Mr. Trotter, Mr. Tufnell, Mr. de Tunzelmann, Mr. Verity, Mr. Vose, Mr. Voysey, Mr. Walby, Mr. Wallace, Mr. Wallis-Jones, Mr. A. F. Ward, Mr. J. Ward, Mr. F. Ward, Mr. Warden-Stevens, Mr. Webb, Mr. R. W. Weekes, Mr. Wilkinson, Mr. J. Wilson, Colonel Wood, Mr. Wood, Mr. A. Wright, Hon. F. G. Wynn, Mr. Young.

The PRESIDENT, after dinner, proposed the usual loyal toast, and referred to the honour of having a member of the Royal family present. He said that the Prince and Princess of Wales had from the commencement showed a great personal interest in electrical development.

Mr. W. H. PREECE, C.B., F.R.S., proposed the toast of "The Learned and Engineering Societies," and in the course of his speech observed that the weapons which scientific and practical men now used were observation and experiment, but the great distinguishing feature that the electricians had introduced into the world had been absolute and accurate measurements. It was by accurate measurement that the last and greatest discovery was produced, principally within the walls of the Royal Institution, where Lord Rayleigh had been able to detect in the atmosphere that which had eluded the observations of thousands of years—the mysterious argon. Science and engineering combined had led to happiness and to rest, and thus it was that the members of the learned societies and of the engineering world were ministers of peace. He coupled with the toast the names of Sir James Crichton Browne, F.R.S. (hon. treasurer of the Royal Institution), and Mr. John Wolfe Barry, C.B. (representing the Institution of Civil Engineers).

Sir J. CRICHTON BROWNE,* in responding, said that the learned societies of all sorts and sizes and denominations regarded the electrical engineers with intense interest and curiosity, with a lively sense of what they had already done for human advancement, and with keen expectancy as to what they were going to do next. The Royal Society, the chief parent of all the learned societies, was of course charged with electricity in every pore, and was indeed one huge transformer. He assured them that the learned societies devoted to the consideration of mental and nervous diseases were compelled to watch them very closely, for it was unquestionable that they were increasing the bulk of the wear-and-tear diseases with which those societies had to deal. There could be no doubt that by their discoveries and their applications electrical engineers had made life more intense and hurried than it formerly was. They had augmented the strain and stress of existence, and so had contributed to the multiplication of wear-and-tear diseases—of those heart diseases, degenerative diseases, nervous diseases that now abounded so copiously around us—and there could be no doubt that they had by the very magic and mystery of their achievements given a definite colour to the wanderings of many disordered minds. He had no hesitation in affirming that the tripod upon which delusional insanity now rests was made up of theology, hypnotism, and electricity, representing respectively the spiritual, the biological, and the physical aspect of man's nature, and not a day passed that he had not in his official capacity to listen to strange tales as to the iniquities of the telephone and the illicit employment of the electric light. But if electricity had swollen the tide of nervous diseases and tipped some of its breakers with foam, it had also brought compensations, for it had given them new and valuable means of treating disease, especially diseases of the spinal cord, and it had given increased facilities for securing the advice of eminent London physicians in cases of nervous disease in any part of the country—facilities of which, he regretted to say, the public still only too sparingly availed themselves.

Mr. J. WOLFE BARRY, replying for the engineering societies, said the future of electric engineering was immeasurable. Civil engineers, whether their business was to deal with the construction of bridges, railways, or docks, were under the deepest obligation to the electrical engineers. They found the use of electricity was more and more necessary and useful in every walk of the profession.

Sir FREDERICK ABEL proposed the toast of "Our Guests," and referred to the pleasure it gave him, as one of the oldest past-presidents, to see such a large and influential gathering. He was glad to see the chairmen of various railway companies present as a mark of the great assistance electrical engineering was to them. Above all, he welcomed the Duke of Cambridge as an illustrious representative of the British Army. In whatever direction progress had been made in the equipment of the army, the Duke had always taken an active lead, and had always been ready to consider carefully proposed improvements in the scientific outfit of both the Royal Engineers and the Royal Artillery.

The DUKE OF CAMBRIDGE, in reply, said that from the position he had had the honour to occupy for such a number of years, he had had the opportunity of judging of the advantages of science in relation to the army. He did not suppose that any profession had gained more by the scientific progress of recent years than the army, and, he might say, the navy. They had now these great services in a condition which certainly when he commenced his career no human being would have thought it possible to

* We are indebted to the *Times* for these verbatim speeches.

Digitized by Google

attain in the period of a man's life. For his own part, he had never thrown any obstacle in the way of valuable and useful improvements which time and science had brought about. Though he had now retired from the army, his reward was that he had gone from it with the affectionate feeling of the army, and, he believed, with the kind and generous feeling of the public at large.

The DUKE OF CAMBRIDGE afterwards proposed "The Institution of Electrical Engineers," and coupled with the toast the name of the President—his old subordinate.

Mr. R. E. CROMPTON, in reply, referred to the tremendous advances made by the electrical industries. He considered that we were on the verge of an electrical age, if not actually in it. The profession was attracting to it the pick of the rising generation. The effects of the advance were difficult to foresee, but the great facilities given by electricity for transport purposes and transmission of power might repopulate country districts. Even if the industries were not more scattered in consequence, electric traction would allow those engaged in the towns to live in the fresh air of the country.

FIRES AND ELECTRIC LIGHTING.

Major S. Flood Page writes to the *Times*, under this head, as follows:

"A considerable time has elapsed since you were good enough to afford me space to demonstrate in your columns that electric lighting properly carried out was the safest of all artificial illuminants. The fact that there have been fires in two central stations and in one electric works in the United Kingdom recently has, to use the words of an insurance writer, created an 'unfavourable impression in the minds of fire managers in regard to this class of risk.' As this impression may be reflected in the minds of some of those who have electric light in their houses, I trust that you will once more have the courtesy to grant me space to say a few words dealing with this important question.

"It will be within your recollection that I based the facts in my previous communication on the annual reports of Captain (Sir Eyre Massey) Shaw. His successor, Captain Simonds, has been kind enough to furnish me with his reports for the years 1892, 1893, 1894, which show that, within the metropolitan area, fires have taken place, caused by candles, gas, lamps, and electricity, as follows:

	1892.	1893.	1894.
Candles	175	235	157
Gas	265	284	284
Lamps	373	456	476
Electricity	1	5	3

So that there have been in three years, from the above causes, 814, 980, and 920 fires, of which only one, five, and three have been connected with electricity, or, taking the total of the three years, there have been 2 714 fires from the above causes, nine of which only have been in places lighted electrically. These facts will surely allay any feeling of anxiety in the minds of users of electric light as to there being any practical danger from electric light properly installed in their houses. They will serve to enforce the argument that by far the safest artificial light ever introduced into common use is the electric light.

"It is, of course, necessary to lay stress upon excellence of work. There is no more shortsighted policy for those who can afford the luxury of electric light than to allow cheapness to weigh, as against quality, when they are having their houses wired and switched ready for the electric light.

"I know nothing whatever about the internal working of the Phœnix Fire Insurance Office. I do not know whether the officials are more careful as to the fire risks they take than other offices, but the experience which we had before has been confirmed, in the past few years, that installations carried out under the stringent and valuable rules of the Phœnix Fire Office are safe and reliable, and I have ascertained within the last few days that the successful record of that company, with regard to electric light, still holds good. Though they were the pioneer company in electric lighting—the first who drafted any rules for our guidance—yet from the commencement up to the present day the Phœnix Fire Office has not had one single sovereign to pay as loss in connection with any fire in any building lighted electrically the installation and wiring of which has been carried out under its rules. Only nine fires for three years, within this vast metropolitan area, is in the highest degree satisfactory.

"I must, however, confess that I view with some alarm the efforts of some electrical engineers who are advocating an increase in, and in some instances actually increasing, the pressure at which they deliver the current of electricity to 220 volts, while the ordinary current has been 100 to 110 volts. It is supposed by some that a difficulty has arisen in the manufacture of incandescent lamps to meet this demand. Permit me to say that the lamp presents the smallest difficulty in connection therewith. A far more serious question, and one which touches very closely upon fire insurance, is whether houses wired with fittings and switches manufactured for 100 volts can safely carry 220 volts. It stands to reason that before this change can be made every house must be inspected, switches, wiring, and fittings thoroughly tested and examined. I have no hesitation in expressing my own opinion that it is far better that we should, for many a day yet, at any rate, be content with the useful safe pressure under which we have obtained the most satisfactory reports which these figures of the Metropolitan Fire Brigade show in connection with fire risks and electric light. I have said, and I repeat, that the lamp is probably the least difficult part of the whole question; but the question itself merits the most serious and earnest attention alike of those who supply and those who are using electric light for domestic purposes.

"Incidentally, I should like to remark that it is very doubtful whether the engineers who are advocating this increased pressure are entitled to do so, for the Electric Lighting Act, under which they are all working, provides that the undertaker shall not exercise any influence whatever as to the lamp which the customer is to use. The words of the Act are as follows: 'Electric Lighting Act, 1882.—The undertakers shall not be entitled to prescribe any special form of lamp or burner to be used by any company or person, or in any way control or interfere with the manner in which electricity supplied by them, under this Act and any license or special Act, is used.'

"The primary sense of these words is probably that the undertakers shall not recommend the lamp of any particular maker; but I think it cannot be denied that they also fairly bear the interpretation that the undertakers may not arbitrarily compel customers to change their lamps, which they must necessarily do if the current is supplied to them at 220 instead of 100 volts In all seriousness, apart altogether from any legal question, this increase of voltage must exercise so important an influence upon that of safety that I trust the most careful consideration will be given by all users of electricity before they will submit to such increase, no matter what inducement may be held out by those who advise them to make the change. If customers in one street are compelled to use lamps of 220 volts, and in another street of 100 volts, it can hardly be denied that the undertaker does prescribe the lamp which is to be used. Even if this increased voltage is intended to be applied to extensions rather than to existing installations, I consider that it is most unwise to raise the question at the very moment when the insurance offices are somewhat uneasy as to the risk involved in central stations and electric works. Rather let us do all that in us lies by excellent workmanship and safe pressure to maintain the satisfactory record of one fire from electricity to every 334 from candles, gas, and lamps within the metropolitan area.

"P.S.—Purchasers of electric fittings should be on their guard; a prosecution is now in progress, a number of men being charged with stamping inferior electric fittings made in Germany with the name of well-known English manufacturers."

INSTITUTION OF ELECTRICAL ENGINEERS, Dec. 12.

The Secretary read the following report of the Council:

Inclusive of the candidates to be balloted for this evening, the total number of additions to the register during the year will have been 216, comprising 12 foreign member, 9 members, 108 associates, and 87 students; and 38 candidates have been approved for election next month; one foreign member and 14 associates have been transferred to the class of members, and 71 students to the class of associates.

The losses which the Institution has sustained by death, although larger than those of last year, are fortunately, below the average; they are as follow: three foreign members, six members, and six associates. Of these we may mention Mr. Aparicio, who was originally in the Spanish Government Telegraph Service, and subsequently the representative of the Direct Spanish Telegraph Company, had been a foreign member for 21 years, and during the whole of that period had kindly acted as our local honorary secretary in Spain, the duties of which office he performed with great assiduity; Colonel Hoskjor, of the Danish Royal Engineers, had been connected with the Institution almost from its formation; Mr. F. L Pope's sad death was specially alluded to at the last meeting; Messrs. Edwards, Greener, and Muirhead, as well as that distinguished officer, Major General Stotherd, R.E., were among the original members of the Institution, and the latter was a member of its first Council Four foreign members, nine members, 21 associates, and 11 students have resigned during the year.

Besides the interesting and highly practical address of the President, papers dealing with nearly every branch of electrical engineering have been read during the year.

In respect to the papers read at the ordinary general meetings during the sessions 1894-95 the Council have made the following awards: the Institution Premium, value £10, to Mr. Mark Robinson (member), for his paper "On the Recent Development of the Single-Acting High-Speed Engine for Central-Station Work"; the Paris Electrical Exhibition Premium, value £5, to Prof. Ewing, F.R.S. (member), for his paper "On a Magnetic Tester for Measuring Hysteresis in Sheet Iron"; The Fahie Premium, value £5, to Mr. J. H. Kingsbury (associate), for his paper "On the Origin and Development of the Telephone Switchboard"; the Students' Premium, value £3. 3s., to Mr. A. C. Eborall, for his paper "On Single-Phase Alternate-Current Motors."

Partly owing to a balance of the scholarship fund remaining

Digitized by Google

unappropriated last year, and partly to the generosity of Sir David Salomons in having this year added £500 to the capital of the fund, the Council are enabled to grant two scholarships of £45 each, and these they have had pleasure in awarding to the following gentlemen: Percy Rhodes Cobb, of King's College, London; Joseph Ernest Petavel, of University College, London.

The general rules for prevention of fire risks from electric lighting drawn up by the Council in 1883, and remodelled in 1888, having by the reason of great advance made in electric lighting become in some respects practically obsolete, a committee of the whole Council have been and are still engaged in their complete revision, and the new rules will, it is hoped, be ready for issue next year.

The recent meeting on the subject of the revised regulations under the Electric Lighting Acts, 1882 and 1888, so admirably presided over by Sir Courtenay Boyle, affords further proof of the desire of the Board of Trade to learn the views of the profession and to meet those views so far as is consistent with their duty to the public. They have consulted the Council of the Institution on important matters on more than one occasion during the past year.

The attendance of members and their friends at the conversazione held at the Royal Institute of Painters in Water Colours on July 3 was, as usual, very large.

Out of the surplus receipts of last year, the Council, as they anticipated, have been able to place the sum of £500 to the credit of the building fund, which now stands at £3,500, and they hope to add a further £500 out of the current year's surplus.

The financial position of the Institution is satisfactory, and the annual accounts, when made up to the end of the year, will in all probability show a surplus equal to that of last year. The following investments have been made during the year—viz, £554. 17s. 8d. on account of life compositions, and £1,099. 19s. 6d. on account of general investment fund.

The roll of the members and associates of the Institution is being continually augmented from the ranks of the large number of engineers who are now employed in the large electricity supply works which are being started in almost every town throughout the United Kingdom. Up to the present time 126 of these works are in operation, employing between 150 to 200 engineers, of whom the large majority are either members or associates of this Institution.

The large number of electro-chemical and electro-metallurgical works which are being opened in those parts of the country where fuel is cheap, and power can consequently be supplied at small cost, are also employing a very large number of our members.

An immense field will doubtless be afforded for the employment of electric engineers by electric traction, which, it is true, is yet in its infancy in this country, but there are signs that during the next few years this Institution will have its ranks largely increased from this source, as in the United States of America. Engineers engaged in electric railway work form a very large percentage of the members of the electrical profession.

The Council believe they are therefore not only justified in congratulating the members on the general position of the Institution, which so largely represents every branch of the profession, but that they are warranted in expressing the opinion that new and important opportunities are about to be afforded both in the United Kingdom and in our Colonies for the exercise of the skill and ingenuity of the electrical engineer.

The Chairman, in moving that the report be adopted and printed in the *Journal of the Proceedings*, thought the Institution might congratulate itself on having been one of the means of bringing the profession into line in reference to the important matters which had been discussed at the recent Board of Trade conference on electric lighting rules with such a satisfactory result.

Dr. John Perry seconded the motion.

Mr. J. S. Raworth wished to say a few words before the report was adopted. He could congratulate the Institution and the Council upon the report, and upon the prosperous position which it showed them to be in. But he thought it was a matter of regret that that report had not asked for greater powers for obtaining the advice and opinions of members upon matters affecting the welfare of the Institution. He was sure, in saying this, that he was representing the feelings of a large part of the members of the Institution, and that being so his sense of responsibility was commensurate with the subject with which he was about to deal. They had at the head of the Institution a Council of which they were all proud, and which was an honour to the Institution and to the profession; but there was a great defect in the mutual relationship between the Council and the body of the Institution. In fact, the Council and the Institution were two separate entities, each of which pursued its own course without knowing the desires of the other. The Council and the Institution resembled a pair of twins which came into the world together, but of which each from that date lived its own life and developed in accordance with its surroundings, so that after 20 years or so, when they were grown up, it might be that nobody would suppose them to have had the same parents. The Institution of Electrical Engineers came into existence 23 years ago, under the presidency of Mr. C. A. Siemens, with a Council and a membership of about a hundred, and in growing up together the want of correspondence between the Council and the members might some day culminate in an actual and tangible danger to the welfare of the Institution. He was sorry to say that if among the body of the members there existed a man who took so great an interest in the progress of the Institution that he not only held opinions, but expressed them, and those opinions did not happen to agree with those of the Council, that man was liable to be called a malcontent. It had happened so. He would call attention to the fact that when there was a question at issue between some of the members and the Council, or at all events some of the Council, it had seemed a proper course to some of those members to call upon the Council in order to represent their views. It would scarcely be believed that they had very great difficulty in even getting the ear of the Council for their representations. And when they did so, the first question put to them was, Whom do you represent? Now, in a case like that, although a man may be certain or nearly certain that he represents the views of almost everyone else in the Institution, he can only formally answer that he represents himself. He (Mr. Raworth) thought that if it was believed that the Institution did run any risk owing to the fact that the Council were not thoroughly in touch with the feelings of the members, then some measures ought to be taken by which, without resorting to the clumsy expedient of a general meeting, the Council could ascertain at any time the feelings of the members and under special conditions could take their advice. For that purpose he intended to propose a committee. Now, it would naturally be urged that the Council was a representative committee. In reality, however, it was not. The Council consisted of 15 movable members, four vice-presidents, and 13 past-presidents, so that in reality there were 17 stuck-fast and only 15 active and lively members who had any communication with the members of the Institution at large, or who had been drawn within a reasonable period from the ranks of those members. In the Institution of Civil Engineers, the owners of the building in which they now met, the past-presidents did not vote on the Council, so that they (the Electrical Engineers), though the younger institution of the two, had actually a more rampant House of Lords than their seniors, with this result that it did not matter what members they put upon the Council to represent them, as the irremovable past-presidents could always outvote them. It followed, therefore, that the Council could not be said to represent the members in the sense that a committee would. Now, they had that evening had placed in their hands a ballot-paper which ought to be a source of congratulation to everyone in the room. In presenting for election Mr. Sydney Morse, the Council had got on to bed-rock. Mr. Morse occupied pretty much the same position between themselves (the Electrical Engineers) and the Board of Trade that the committee he was proposing would occupy between the Council and the members.

The Chairman said Mr. Raworth must confine himself to the subject of the report. In speaking of the composition of the ballot-list he was certainly travelling outside that.

Mr. Raworth said that in that case he would only mention the satisfaction expressed by everyone at the selection of Dr. John Hopkinson as president. In that matter the Council had made a big score, though he could not say they had made it off their own bat. They had borrowed for once the bat of the Institution, and he hoped they would continue to use it. He moved, "That this meeting considers it desirable in the interests of the Institution to form a committee to represent the views of the members in consultation with the Council, and that such committee is hereby constituted with the following members: Messrs. A. A. C. Swinton, R. P. Sellon, W. P. Fawcus, A. B. Holmes, A. W. Heaviside, H. A. Mavor, J. C. Vaudrey, and E. Manville, with power to add to their number."

The Chairman: Is this a resolution or an amendment to the report?

Mr. Raworth said he was quite willing that it should be put as a resolution after the report.

The report was then carried unanimously, and **Mr. Raworth** rose immediately and filled in the names to the resolution as above, when

Mr. G. L. Bristow (the honorary solicitor) said the resolution was not within the power of the meeting. Under the wording of Clause 55 of the articles, the business of the annual general meeting was to receive and deliberate upon the report of the Council upon the state of the Institution, and to elect the officers for the ensuing year. That was the only business that could be brought before the meeting. Mr. Raworth's resolution must be brought forward at an ordinary general meeting after notice given. It was altogether beyond the powers of the meeting to entertain it at present. He would suggest that the resolution might be sent to the Council with a request that they should consider the best way to bring it forward.

Prof. Perry: Our difficulty is this, that you, sir, gave the meeting the idea that it might either be brought forward as a resolution or as an amendment.

The Secretary, who was standing beside Prof. Perry, was understood to say that he asked Mr. Raworth if he preferred to move it as an amendment or a resolution.

Prof. Perry: Sir, I say you did not; it was the President who spoke. In all fairness, Mr. Raworth should have the right to consider this either as a motion or an amendment to the report.

The Chairman said, when there was any doubtful point, the natural course was to refer to the honorary solicitor and ask what was the legal course to pursue. Their solicitor said that the safest way was to bring the resolution forward at a general meeting. What would be the use of himself or anyone unlearned in the law flying in the face of that advice? Mr. Raworth's object would be best obtained by following the course recommended.

Mr. A. A. Campbell Swinton thought the matter could be discussed since it referred to "the state of the Institution."

The Honorary Solicitor said if the members wished to express their opinions he thought they might do so, but it would be out of order to pass the resolution.

The Chairman suggested that if the question were postponed the meeting could proceed to discuss more interesting matter.

Digitized by Google

Mr. Mavor thought no matter could be more interesting to the meeting, and **Mr. Swinton** agreed with this.

Mr. Raworth said he had been caught in a trap. He was naturally indisposed, if his object could be otherwise obtained, to carrying an amendment to the report, since that course had the appearance of a vote of censure. The effect of the action of the chairman had been to prevent that general meeting going on with the question, and had placed him and those that thought with him at a very great disadvantage.

The **Chairman** said, if Mr. Raworth had been trapped, it was accidentally. He (the Chairman), when he spoke, was certainly not aware of the effect that would follow. The advice of the solicitor was not given until after he had spoken. It, however, certainly appeared to him very inconvenient to discuss the question now and finish it some other day. He did not think the present one was a particularly large meeting. They would get quite as large a meeting to discuss it if they postponed the matter to the beginning of next year.

Mr. Raworth thought, if it was not possible to take a vote, it would be no use going on with the discussion. He, however, suggested that members present might give some little indication of their views in the usual manner, and this was followed by considerable applause.

Mr. H. W. Handcock remarked that the matter was one that could scarcely be settled in a single night. If it was to be decided at the next meeting it would be well to discuss it at the present meeting, so that members might have some idea of what was to be said for the proposition and against, and time for consideration. It might be that if they settled upon this committee to advise the Council, the next thing to do would be to appoint a second committee to advise the committee He thought rather they might follow the practice of the Institution of Civil Engineers. It was possible that some of the members moved in different circles to those in which the Council moved, but if it could be arranged that the past-presidents did not vote on the Council, and if the method of electing the council were slightly modified, it would be possible for the members to be properly represented there. They would thus still retain the experience of the past-presidents, and yet the Council would be representative of the ideas of the members of the Institution He thought it would be far better to continue the discussion than simply to spring a resolution upon a meeting to be settled perhaps in half an hour.

The **Chairman** said the best course would be to put it to the meeting whether the discussion should continue or be postponed, and, this being done, the show of hands was in favour of continuing the discussion.

Mr. Raworth proposed to put the meeting in order by moving that the meeting invited the President to call a special meeting to discuss the discussion.

The **Chairman** said that it was only necessary to get 10 members to request a general meeting, and the Council must call one within seven to ten days of the requisition.

Mr. H. Brat Harrison remarked that there was great difficulty at the present time in the way of any member bringing a suggestion before the Council. The knowledge any individual member could have of the general feeling of the Institution was confined to what he learned from his personal friends, who necessarily formed but a small portion of the whole list of members When a member found that among his own friends a certain change was desired, he could only speak in an informal manner to some member of the Council whom he happened to know, and under the circumstances he naturally appeared to represent only a very few members. If a committee were appointed that difficulty would be got over, as each member of the committee would be more or less the representative of a great number of members, and the Council would know that anything they proposed did not represent merely the views of a small clique. He did not, however, think it would be possible that evening, or in any one evening, to bring before the Council all the suggestions which members would now like to make, and that was why they wanted a committee who in the future could bring before the Council the various suggestions as they arose. The deliberations of the Council were private, and it might happen that the committee would have to bring before the Council certain matters which it would be well should not be brought forward in that room at what was practically a public meeting. He therefore supported the proposal.

Mr. Shoolbred suggested that it would be interesting to know how far the practice of the Institution in this matter was in accordance with that of other professional and learned societies He thought there might be a direction to the committee to ascertain the position of things in this respect

Mr. A E. Mavor thought he had perhaps more opportunities than many of them of meeting members of the profession who were scattered over the country or even in London and who never reached that hall. Without wishing to go beyond the subject of the discussion, he did not think that they were entitled to congratulate themselves as they had done in the report on the accession of members to their body. There were many active and energetic members in the profession who did not belong to the Institution, and did not care to belong. The past presidents, by their very eminence, were apart from the body of the members. The desire that the Council should take the younger members more into consideration was one that in his opinion, ought to be acceded to. He had no experience as to what a contested vote on the Council was like, but he did not believe for a moment that the past-presidents would oppose a general wish of the Institution All he asked was that the Council should know better what those wishes were, and that he asked in the name of the younger members of the profession. This was not the first time in the history of the Institution that circumstances had disarmed their action in the matter, and he thought that their articles of association ought to be so altered that they could understand them. Legal advice was doubtless very valuable, but it was much more valuable to know enough of the law to be able to do without your lawyer. He thought the articles should be put in plain English that everyone could understand.

Mr. G. L. Addenbrooke said that he considered that the matter had been sprung upon the meeting without due notice. A committee formed to represent the members might take far too much upon themselves. He had had experience of a somewhat similar experience in connection with the Photographic Society, of which he was a member. A committee was appointed on somewhat similar lines and after a long series of discussions, extending over a whole year, it had drawn up most democratic rules which had been a stumbling block in the way of the progress of the society. By these rules almost every matter had to be referred to the members, and hence a great deal of expense had to be incurred in printing and circulating notices. The continued waste of time caused a feeling of disgust amongst the members, and finally the repeated notices were neglected entirely.

Mr. R. S Erskine, speaking of the present method of electing the Council, complained of the short time allowed between the time the list was issued and the date of the election. He said there was practically no time allowed to organise an opposition after the list was made public. He would suggest that the names of the gentlemen proposed by the Council should be exhibited at the offices of the Institution at least six weeks before the date of the election

Mr. A. A. Campbell Swinton supported the last speaker, and rebuked Mr. Addenbrooke in a most dignified manner. He said they did not wish to follow in the steps of any Photographic Society, but rather to learn from the senior engineering societies, such as the Institution of Civil Engineers or the Institution of Mechanical Engineers Unless the list of proposed new members of the Council was published earlier than at present, it was impossible to take concerted steps to modify the list at the election. while without concerted action the ballot could effect no useful purpose. He understood that in the case of the Institution of Mechanical Engineers the list was made public a month or more previous to the ballot papers being sent out, and he thought that the Electrical Engineers might follow this example with advantage.

Mr. J. Hardie McLean thought that the opposition were taking up a false position. They demanded six weeks' notice for the Council list, but had not given six minutes' notice when springing the resolution on the meeting. The gentlemen who had spoken might have the support they talked of from some of the members, but at least they had not approached him in any way to learn his views, and he was not prepared at a moment's notice to give his vote one way or the other, and demanded proper notice to consider this important question.

The discussion was then closed by the **President**, who said that the matter would need careful consideration.

The usual votes of thanks to retiring officers were then proposed and seconded.

The **President** then announced that the whole of the gentlemen on the balloting lists were elected, and adjourned the meeting till January 16 1896.

THE PHYSICAL SOCIETY.

A special general meeting of this society was held on December 13, Prof Reinold, vice-president, in the chair.

The resolution with reference to the change in the amount of the life-composition fee passed at the special general meeting held on November 22 last was confirmed.

The ordinary meeting was then held.

Dr. John Shield read a paper on "**A Mechanical Device for Performing the Temperature Corrections of Barometers.**"

A paper by **Prof. Rucker** on "**The Existence of Vertical Earth-Air Electric Currents in the United Kingdom**" was, in the absence of the author, read by **Mr. Kay**. In a paper read before the British Association at Oxford, Dr. Schmidt stated that he had expanded the components of the earth's magnetic force in series, and had deduced expressions, two of which give the magnetic potential on the surface of the earth, in so far as it depends on (1) internal and (2) external forces. The third series represents that part of the magnetic forces which cannot be expressed in terms of a potential, but must be due to electric currents traversing the earth's surface. Dr. Schmidt concluded that such currents amount on the average to about 0·1 ampere per square kilometer. The author has tested this conclusion, drawn from the state of the earth as a whole, by means of an examination of the line integral of the magnetic force taken round a re-entrant circuit, taken in the United Kingdom. The necessary data have been obtained from the results of the magnetic surveys for the epochs 1886 and 1891, carried out by the author and Dr. Thorpe. Two circuits, called the α and β circuits, were selected, having their greatest extension N. and S. and E. and W. respectively. The work done by a unit magnetic pole on traversing these circuits was calculated for the epoch 1886 by means of the terrestrial lines found for that date, and also for the epoch 1891 by means (1) of the same lines when due allowance was made for secular change, and (2) of the independent set of lines found by aid of the 1891 survey. The same calculation was made for a third circuit (γ), using instead of the calculated terrestrial lines the true values of

Digitized by Google

the forces and declinations as deduced from the nearest stations. The following table gives the results in amperes per square kilometre:

	α	β	γ
1886	−0·026	−0·004	—
1891 (1)	+0 001	−0·005	—
1891 (2)	--	—	−0·008

From these figures the author concludes that there is not in the United Kingdom at any rate a vertical current amounting on the average to 0·1 ampere per square kilometre.

Mr. Watson said a few words on the difficulty experienced in determining the line integral in South Wales due to the presence of closed curves.

The society then adjourned till January 24, 1896.

LEGAL INTELLIGENCE.

NORTH METROPOLITAN TRAMWAYS COMPANY v. THE LONDON COUNTY COUNCIL.

The Master of the Rolls (with Lord Herschell and Lord Justice Kay) has heard an appeal by the North Metropolitan Tramways Company from the judgment of Mr. Justice Romer, in May last, holding that the London County Council were entitled to compulsorily purchase so much of the plaintiffs' tramways—and, consequently, so much of each separate London tramway scheme—as is within the Council's district, without purchasing the whole of the undertakings as one concern. The separate schemes, it was argued below, had legally been amalgamated into one undertaking, and consequently the time for compulsory purchase would not arrive until the expiration of 21 years from the last constructed of the series, instead of, as the County Council submitted, their being able to purchase each separate undertaking within this period after its becoming an accomplished fact.

Mr. Cripps, Q C., appearing for the company, argued for nearly two hours upon the grounds he enforced before Mr Justice Romer, but which the learned judge rejected—that by the appealing company's special Act of 1890 a parliamentary bargain was made which, in the peculiar circumstances of the case, fixed the time at the expiration of which the local authorities might compel the different companies to sell their tramways at 21 years from the passing of the respective Acts instead of from the passing of the general Act of 1870 dealing with the subject.

At the close of the learned counsel's submissions, without calling on Sir Edward Clarke, Q C., who, with Mr. Fletcher Moulton, Q C , appeared for the London County Council, each of their Lordships, speaking at some length, dismissed the appeal, each, in effect, holding that the rule of construction applying to a private Act was that it could not alter a public Act except by express words, which words were not included in the appealing company's Act in this case, and that a private Act must be held to have the same meaning as the general one unless there was something in the subject repugnant to such construction.

Lord Herschell took the same view as to the rule of construction and the effect of adopting Mr. Cripps's suggestion, and **Lord Justice Kay** concurring, the appeal was dismissed.

COMPANIES' MEETINGS AND REPORTS.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED, IN LIQUIDATION.

The final meeting of the shareholders of this Company was held on Tuesday, the 17th inst., at the offices of the Company, to receive the liquidator's accounts of the winding up of the Com pany, Major S Flood Page, in the absence of the chairman (Mr. James Staats Forbes), presiding.

The **Chairman** said: We meet, not really to bury the pioneer of electric enterprise for it is not quite dead—phœnix-like, again it rises from its ashes in the Edison and Swan United Electric Light Company, Limited. Those of us who can go back to the time of the inauguration of the Swan Company can realise what a very great work in this country was done by it. It must be a gratification to you, as it is to us all. to know what probably not many of you are aware of, that Mr. Swan began his investigations in connection with the electric light in the year 1845, and it is a pleasure to know that he is still among us, giving us invaluable aid and assistance in the work that we have to do now. It is interesting to think that Mr. Swan should have been able to keep working for the Company so many years, and to live to see the marvellous change which has been brought about by the introduction of the electric light. We have some gentlemen here present who took an active part in the formation of the old Swan Electric Lighting Company. That was at the time when lamps cost 17s. 6d. each to make, and were what we should now consider to be of very poor quality. Then we come to the time when the price was reduced to 12s. each, and that was looked upon as an enormous advance, but now we are selling lamps at 1s. 9d. each in the face of great competition.

The **Liquidator** then presented his statement of the distribution of assets, and it was resolved, "That the accounts submitted to this meeting, and showing the manner in which the winding up has been conducted, and the property of the Company disposed of, be received and adopted, and that the books and papers of the Company and of the liquidator be handed over to the Edison and Swan Company."

Mr. Swan seconded the resolution, and said that it was always a melancholy thing to assist at a funeral, but the chairman had been pleased to speak of its resurrection in the Edison and Swan Company. The remarks of the chairman had aroused in his recollection many interesting reminiscences of the vicissitudes of the Company, the old Swan Company—and the Swan United Company—and he was glad that he had been able to assist in giving the people a more wholesome and a better light than before. The changes of the companies which had taken place had not always been agreeable to him, but he had not opposed them, because he had supposed them to be in the interest of the shareholders: in a number of instances he had suppressed his own feelings and his own interests, in order that a better chance of success might be given to the Company. He believed that the Edison and Swan Company had a long and prosperous career before it.

The resolution was then put, and carried unanimously.

FROGGATT'S ELECTRIC LIGHTING COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Monday at Winchester House, Old Broad-street, E.C., Mr. C. de Murrieta presiding, to consider resolutions for winding up the Company and appointing Mr. W. P. Eldrid, chartered accountant, liquidator.

The **Chairman** expressed regret that, in consequence of the failure of their efforts to obtain further capital, it had become impossible to carry on the business. He regretted this the more because everything pointed to a promising future provided that certain modifications in the working and administration of the Company were carried out. He need not trouble them with a recital of the difficulties with which they had had to contend—difficulties which were inherent to every pioneer enterprise. He would only say that they had earnestly laboured without reward in the interests of the Company, and had at least shown that the system adopted by the Company was well conceived, and in happier circumstances might still achieve success. But all the available funds being exhausted, and no response having been made to the proposal for issuing preference shares, the best, and, indeed, the only course to pursue was to wind up the Company, and it was suggested that Mr. Eldrid, their auditor, should be appointed liquidator. That gentleman was acquainted with the working of the Company, and was thus well qualified to judge of the best means of disposing of the assets, or, if possible, the manner by which a reconstruction might be effected.

Mr. Philip Hall said it was a very serious matter for the shareholders that in about 12 months' time a company like theirs should have to be wound up, and he hoped that something might be done either to reconstruct it or to sell its rights to a larger company, which would be more likely to make the enterprise a success

The **Solicitor** (Mr. W. L. Cooper) stated that efforts had been and were still being made with the object mentioned, and it was hoped that the liquidator might be able to carry those efforts to a successful issue. It was, however, necessary to take the steps now proposed, or the assets of the Company would be dispersed by execution creditors.

On the motion of the **Chairman**, seconded by **Mr. Froggatt**, resolutions in accordance with the object of the meeting were unanimously passed.

BRITISH STEAM GENERATOR AND REFUSE UTILISATION COMPANY, LIMITED.

At the Companies' Winding-up Offices, Carey-street, E.C., last Friday, the meeting of the creditors and shareholders of the British Steam Generator and Refuse Utilisation Company, Limited, was held before Mr. Winearls, assistant provisional liquidator. The Company was formed in June 1893, with a nominal capital of £600,000, for the purpose of acquiring patents for furnaces for the destruction of refuse of large towns, the resulting forces produced therefrom being used for the production of cheap electricity or the generation of steam power. The purchase price was to be £470 000 in fully-paid shares and £30,000 in cash. The vendor, the executrix of the patentee, however, alleges that she has only received £286 in cash Some £216,590 of shares have been allotted, in respect of which no cash was received by the Company; and further, one of the patents has lapsed owing to the money paid to satisfy the patent fees being used by the person to whom it was paid for other purposes

The **Chairman** stated that in September, 1892, an installation was set up at Halifax to show the utility of the invention and the wonderful revolution which was going to be worked in the utilisation of refuse It was reported favourably upon in the provincial Press. From statements made by Mr. Glaskin, it appeared that a report he had addressed to the directors had been used by the promoter as a means of obtaining cash advances from various persons, and that those persons had notified the Company that they claimed a charge in respect thereof on part of the share capital Representations had been made to the Official Receiver that in some case the advances were made on the distinct understanding that they would be applied in pushing the invention with a view to the Company being formed. On the other hand, it was stated that those advances had been made to the promoter personally, and not as representing the Company. The only assets

Digitized by Google

of the Company consisted of the three patents, the installation at Halifax, and 100,000 shares in the London Refuse and Steam Generator and Electrical Power Corporation, Limited, already held by creditors for advances. The details of the liabilities had not yet been obtained, but they were roughly estimated at £2,500, in addition to the liability to the vendor.

After a short discussion it was resolved to leave the winding up in the hands of the Board of Trade.

DUBLIN SOUTHERN DISTRICT TRAMWAYS COMPANY, LIMITED.

A special general meeting of the shareholders in this Company was held on December 11 at Clare-street House, Bristol, Mr George White, chairman of the Company, presiding.

The **Chairman** explained the proposed extensions of the Company's system in Dublin, and the necessity for further capital, all of which would be subscribed by the present shareholders, and it was unanimously agreed to increase the capital as recommended by the Board.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brumath.—The Town Council invite tenders for lighting the town by electricity, steam power to be used. Conditions from Bürgermeister A. Bostetter, Brumath-i-Els., Germany.

Orduna.—The municipal authorities invite tenders for the execution of a waterworks and electric lighting scheme. The estimate is 84,729 pesetas. Particulars of El Ayuntamiento de Orduna, Spain.

Betanzos.—Tenders are invited by December 28 for the concession of the electric lighting for 25 years of the town of Betanzos, Spain. Conditions of La Direccion General de las Administraciones Locales, Madrid.

Ploesti.—The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town. Conditions from La Mairie de Ploesti, Roumania.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Langeac.—The municipal authorities invite tenders for lighting the town by electricity during a period of 40 years. Water power is available. Specifications of M Grenier, conducteur des Ponts-et-Chaussées à Langeac (Haute-Loire), France.

Cleator Moor.—Tenders are invited for an electric light installation in the central stores of the Cleator Moor Co-operative Society. For particulars apply to Mr. J. C Teasdale, secretary, General Office, Co-operative Society, Limited, Cleator Moor, Cumberland.

Aussig.—The communal authorities propose to have built a seven-mile single line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Pernambuco.—Tenders for lighting the city of Pernambuco by electricity are invited by the Government of the State of Pernambuco (Brazil). Particulars may be had on application to the Brazilian Consulate-General, Liverpool, or to the Brazilian Consulates in London, Manchester, and Glasgow.

Dublin.—Messrs Arnott and Co., Limited, Dublin, invite tenders from competent firms for electric light and power installation to their new premises, Henry-street and Princes-street, Dublin. A copy of specification can be obtained from Mr. George P. Beater, M.R.I.A.I., architect, 17, Lower Sackville street, Dublin, on payment of £5. 5s., which will be returned on receipt of bona fide tender, which must be delivered at architect's office on or before January 8, 1896, endorsed "Electric Installation, Arnott and Co., Limited.

Chelsea.—The Guardians of St. Luke, Chelsea, invite tenders for fitting up an electrical wiring installation, with fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. Particulars upon application to the Guardians' architects, Messrs. Lansdell and Harrison, 12, Compton-terrace, Highbury, N., on depositing with them £5, which will be returned to those sending bona fide tenders not later than 12 o'clock noon on December 31, 1895 addressed to Mr. Wm. Miller, clerk to the Guardians, Guardians' Offices, 250, King's-road, Chelsea, S.W.

Durban (Natal).—The Corporation desire tenders for the supply, for delivery at Durban, and fixing at Durban, of steam and electrical plant for the lighting of the borough by electricity. The work will be executed under the direction of Mr. Fletcher (borough engineer) and Mr. Hadfield (electrical engineer) at Durban. The plant required includes high-speed engines, dynamos, cables, arc and other lamps, accumulators, etc. Specifications and plans can be obtained from Mr. W. H. Radford, C.E., Angel-row, Nottingham, consulting engineer to the Corporation, on deposit of £5. 5s., which will be returned on receipt of a bona fide tender. Sealed and endorsed tenders, in duplicate, must be delivered at the offices of Messrs. Webster, Steel, and Co., agents to the Durban Corporation, 5, East India-avenue, Leadenhall-street, London, E.C., by 28th inst.

RESULTS OF TENDERS.

Hampstead (London).—The Vestry have accepted the offer of Messrs. Siemens Bros, of Queen Anne's-gate, to take entire charge of the arc lamps in Finchley-road for a period of eight weeks, providing all necessary carbons and labour for trimming, etc, for the sum of £35. 10s.

Bradford.—On the recommendation of the Gas and Electricity Supply Committee, the Corporation have accepted the offer of Messrs George Scott and Son, of Liverpool, to supply and fix at the chemical works, Frizinghall, for the sum of £1,350 a plant required in an extension of the works.

Llandrindod Wells.—The Urban District Council have resolved to accept the offer of Mr S Jevons, of Birmingham, to carry out the work of lighting the town by electricity. The price tendered was 45s. per annum each for 70 incandescent public lamps of 32 c p. for eight months of the year, to burn from dusk to 11 p.m. Mr. Jevons will provide all cables and fittings, utilising the present lamp columns as far as possible, but the ratepayers will have to pay about 3s. 6d. per lamp per annum for new lamps, repairs, etc., and also the cost (about £200) of burying the cables if overhead wires are objected to.

BUSINESS NOTES.

Southwick (Sussex).—The inhabitants of Southwick village have adopted the Lighting Act.

Nantwich (Cheshire).—The Urban District Council have expressed themselves dissatisfied with the present gas-lighting.

Eccles (Manchester).—A meeting of ratepayers has protested against the proposed introduction of the electric light into the borough.

Whitehaven.—The Town Council have requisitioned Dr. Hopkinson to advise them in connection with the existing electric light installation.

Stirling.—The Police Commissioners who have obtained an electric lighting order, are now proposing to approach the gas company with a view to purchase.

Wolverhampton.—The sanction of the Local Government Board has been received for the Corporation to borrow another £5,000 to extend the electric lighting works

Reading.—The Reading Installation Company, of the Arcade, have issued a special illustrated catalogue setting forth the advantages of electricity as an illuminant over gas.

Catalogues.—Messrs. Clarke, Chapman, and Co., Limited, of Victoria Works, Gateshead-on-Tyne, forward us a copy of the 1896 edition of their well got up catalogue of electrical machinery and appliances.

Shrewsbury.—In consequence of support already received and promises given, the directors of the Shropshire Electric Light and Power Company have reduced the retail price of their commodity from 8d. to 7d per unit.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended December 15 amounted to £1,081, as compared with £917 in the corresponding week of last year, being an increase of £164

Devonport.—The corporate seal has been affixed to a memorial in support of the application to the Board of Trade for a provisional order for the supply of electricity within the borough for public and private purposes.

Brush Electrical Engineering Company, Limited.—The transfer books of the 4½ per cent. second debenture stock are, in view of the interest payable on January 1, 1896, closed from December 18, 1895, to January 4, 1896.

Ashbourne (Derby).—Plans and sections of the Derby and Ashbourne Tramway, relating to the part to be constructed within the urban district, have been laid before the Urban District Council, and were referred to the Highways Committee.

St. Austell (Cornwall).—The Urban District Council have instructed the Lighting Committee to prepare a specification on which the electric light and gas companies might be invited to tender for the lighting of the principal streets.

Hornsey (Middlesex).—The Lighting Committee of the District Council have recommended "that the application of an engineer in reference to the lighting the streets and buildings in the district with electricity cannot at present be entertained."

Stonehouse (Plymouth).—The *Western Morning News* says that if the gas company "want to encourage promoters of electric light undertakings they cannot do better than continue to supply poor gas, and little of it, as they have done this week."

Bonsall (Derby).—The Urban District Council have resolved that enquiries of various firms be made as to the cost of the construction of plant for the manufacture of gas and for electric lighting for the requirements of a district with a population of 2,000.

Wakefield.—Alderman Sherwood, in moving the adoption of the Electric Lighting Committee's report, said they were getting on as rapidly as possible, but would not be able to proceed much further until the Sewage Committee had decided as to the site.

Watford.—Councillor Andrews has given notice that he would at the next meeting of the Urban Council move that a committee be appointed to consider the advisability and practicability of applying for a provisional order under the Electric Lighting Act for Watford.

Digitized by Google

Metropolitan Electric Supply Company, Limited.—Payment by warrants will be made on January 1 next of interest for the half-year ending December 31 on the 4½ per cent. first mortgage debenture stock The transfer-books are closed from the 18th to 31st inst., both d ys inclusive.

Electric Insulation Syndicate, Limited.—This Company has been registered. Capital £5 000, in £10 shares. Objects: to enter into an agreement with J. P. Whitaker and F. G. Treharne for the acquisition of certain patents, and to develop and turn to account the same in such manner as the Company shall see fit.

Withington (Lancs.).—In the last minutes of the General Purposes Committee of the Urban District Council it was stated that the surveyor had submitted tenders which he had obtained for the electric lighting of the Town Hall throughout. The Council resolved that the matter should remain in abeyance until Aprli.

Islington (London).—It has been stated at the meeting of the Vestry that the contractor for engines, boilers, and steam plant has definitely promised that the machinery shall be running by the 31st inst., and that the official test will be immediately applied, and the supply of electricity made available on January 1, 1896

City and South London Railway.—The returns for the week ended December 15 were £1 014, compared with £962 for the corresponding period of 1894, being an increase of £52 The total receipts for the half-year 1895 were £21,541, compared with £21,480 for the corresponding period of 1894, being an increase of £61.

Metropolitan Asylums Board.—We learn that the order for the steam-engines for the Brook Hospital has been given to Messrs G. E. Belliss and Co, Limited, of Birmingham. It speaks well for the Belliss double-acting, self-lubricating engine that an exception has been made in its favour to run at a speed specified for single-acting engines.

Bangor (co. Down).—A special meeting of the Town Commissioners has been held for the purpose of considering the advisability of applying to the Local Government Board for a license to have the town lighted with electricity, and it was resolved that the cost of obtaining the license be ascertained before a decision was adopted.

York.—The Streets and Buildings Committee of the Corporation have received a letter from Prof Kennedy accepting the conditions under which the committee desired him to act as adviser to them on the question of electric lighting for the city. Prof. Kennedy further intimated that he would fix an early date to make a survey of the city for the purposes of his report.

Coventry.—The Estates and Finance Committee have reported to the Town Council that the adoption of the electric light for the free library is quite beyond their means, and the only course open is to place the matter before the Estates and Finance Committee and ask their assistance The sum required is £140, and the committee recommend that it be provided out of the borough fund.

Bolton.—The electrical engineer (Mr. J. H. Rider, M I E.E) has been instructed by the Gas and Electricity Committee of the Corporation to prepare a report and estimate of the cost of the extensions necessary to be made in the plant at the electricity works. In his report to the committee the engineer stated that 96 consumers were now connected, and that five others would shortly be ready.

Sheffield.—Since the last Council meeting the future of the Sheffield tramways has been the talk of the town, and the interest manifested in the matter is increasing. Mr. W. Page, the engineer of the syndicate which proposes to establish the extensive system of electric trams to supersede the present inadequate arrangement—should Parliament allow them to do so—has been in Sheffield engaged in the preparation of the estimates.

Fleetwood.—Respecting the proposed electric tramway between Fleetwood and Blackpool the Urban District Council have received a letter from the promoters of the scheme enclosing statutory copies of the notice of the proposed application to next session of Parliament for powers, and asking the Council to signify whether they assented to, dissented from or were neutral to the same; and it was decided to reply that the Council remained neutral.

Cheltenham.—One of the Corporation employés has met with his death whilst engaged in one of the transformer-chambers in the centre of the town. The man, John Pugh, about 28 years of age, and belonging to Wolverhampton, previous to coming to Cheltenham about four months since, was in the employ of Messrs. Callender and Co, and was considered a skilled workman. It is presumed that the unfortunate man had neglected to take the precautions usual under the circumstances.

The Eastern Telegraph Company, Limited.—The directors announce the payment, on January 14 next, of interest of 3s. per share, less income-tax, being at the rate of 6 per cent per annum, on the preference shares for the quarter ending December 31, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits for the quarter ended September 30. The transfer books will be closed from January 7 to January 14, both days inclusive.

City of London Electric Lighting Company, Limited.—The transfer books of the debenture stock will be closed from 23rd to 31st inst., both days inclusive, for the purpose of preparing the warrants for the interest due January 1, 1896. Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to City of London Electric Lighting Company, Limited, provisional certificates of a further issue of £100,000 5 per cent. debenture stock.

Appointments Vacant.—The Salford Corporation have a vacancy for an assistant electrician for a central station. Applicants must have had experience of high-pressure alternating-current system, and be capable of testing cables, house wiring, transformers, and meters. The Lighting Committee of the Dewsbury Corporation have a vacancy for an improver, to act also as dynamo attendant, in their electricity supply station. Particulars will be found in our advertisement columns.

Bexhill (Sussex).—The Urban Council have adopted the following resolution: "That the Urban District Council of Bexhill hereby give their consent to an application by or on behalf of Robert Kersey and the Honourable Gilbert George Reginald Sackville, commonly called Viscount Cantelupe, to the Board of Trade for a license under the Electric Lighting Acts, 1882 and 1888, to supply electricity for public and private purposes within the whole or any part of the urban district of Bexhill, in the county of Sussex"

Ashton-under-Lyne.—The Town Council have resolved: "That the Mayor, Aldermen Andrew, Heginbottom, Hilton, Siddall, and Wilson, and Councillors Andrew, Catlow, Cooke, Hall, Hallam, Kelsall, A E Mellor, Newton, Phillips, and Shaw be appointed a committee to be called the Electric Lighting Committee, and that such committee be authorised to adopt such measures and to make and complete such arrangements as may, in their opinion, be necessary and desirable in order to carry out and give effect to the Ashton-under Lyne (Corporation) Electric Lighting Order of 1892"

Aberdeen—The Lighting Committee of the Aberdeen Town Council have decided to try the experiment of lighting the streets with electric overhead lamps. The lamps will be suspended over the middles of the thoroughfares on wires. The streets selected for the experiment are Broad street and Bridge-street. The Gas and Electric Lighting Committee of Aberdeen Town Council have agreed to place in the depôt, in Union-street, a few electromotors for exhibition. These are to be made to drive small sewing machines, etc., in order that the public might see to what extent electricity can be utilised.

Pupils.—We understand that the London Electric Supply Corporation have decided to take a limited number of pupils at a small premium. The custom of the corporation hitherto has not been to take premium apprentices, but owing probably to the valuable practical training received by the engineering staff, and the important appointments obtained by former employés, applications to be taken on the engineering staff have lately largely increased Doubtless these applications are mainly the result of the success which has followed engineers who have received their training with the corporation.

Queenstown.—The streets of Queenstown were left in a state of darkness on Saturday night and succeeding nights. This state of things is the result of a dispute between the Queenstown Town Commissioners and the local gas company. The latter body served notice on the Town Commissioners on the 11th inst. threatening to extinguish the lamps if the Commissioners did not enter into a contract for public lighting for a term of two years. The town clerk informed the gas company that the Commissioners could not legally deal with the matter until after the 14th inst. In spite of this the gas company have executed their threat.

Torquay.—The Town Council seem at last seriously determined to tackle the electric light question. They have only another six months before their provisional order expires, so that it is time they were up and doing Once again the whole subject is referred back to the Electric Light Committee, of which Alderman Kerswill continues chairman. The instructions to the committee are to make enquiries as to a suitable site for the station, apart from the Bath Saloons, to canvass the town for likely customers for the new light, and to call in another expert. Generally speaking, councillors are in favour of the introduction of electricity, but they fear a possible addition to the rates.

Copper.—Messrs. Henry R Merton and Co.'s fortnightly statistics show that, although the stocks of copper have declined by 170 tons since the end of November, the price of Chili bars has also fallen 5s. a ton. Notwithstanding rather larger supplies from North America, the deliveries exceeded the arrivals by 170 tons during the fortnight—which is satisfactory evidence of the continued growth of consumption At the present time the stocks of copper in England and France and afloat are only 45,561 tons—a smaller amount than has been recorded for many years past; yet there is the remarkable fact that on July 31, when stocks were 10,000 tons larger, the price was £47 a ton, against £42. 17s. 6d. now.

Gravesend.—The Works and Finance Committees of the Town Council conjointly, in reference to the letter of Messrs. Riley and Co, read at the last meeting, had before them a further letter from this firm, in which they stated they proposed to defer supplying the information for the present, as they found they were out of time to make a formal application for a provisional order until the autumn of next year. The Joint Committee were unanimously of opinion that "the application submitted to the Council had evidently been misconceived by Messrs Riley and Co, and that no inducement should be held out to such contractors to make any further application to the Council." The minutes were confirmed.

Linlithgow.—The Police Commission have received the report of the committee appointed to take into consideration the cheapest and most effective method of lighting the town, reported that "the present price of electric light was about three times the price of gas, but that certain improvements were being carried

Digitized by Google

out at the present time which were thought would have a good effect in materially reducing the cost of electric light." The committee were also of opinion that nothing could be done with the taking over of the present gas company's works till the end of next year, and they, therefore, recommended that the matter be held over for future consideration. The Commission agreed to the committee's recommendation.

Buxton.—The Urban District Council have adopted the following report of the Electric Lighting Committee: "After full consideration the committee feel that, having in view the position of Buxton and the various advantages and disadvantages of electric lighting *versus* gas lighting, it is not desirable to take any steps to erect an installation in the town for the present They would suggest that the discussion be adjourned for 12 months, and that an application be made to the Board of Trade for an extension of the time when the powers under the Buxton Electric Lighting Order shall lapse." Councillor Willoughby said that he could only regret that the newly constituted Electric Lighting Committee had come to such an untimely end.

Bradford.—The Gas and Electricity Committee of the Bradford Corporation have had some cause for anxiety in regard to the exceptional demand for the supply of electric light which is expected to come at Christmas. Since the commencement of the Corporation installation there has hardly been a day when the committee could boast that it had satisfied all present applicants for the supply, and latterly it has been badly hampered by various misfortunes in connection with the putting in of additional machinery. Very special efforts, however, are being made to cope with the strain of the Christmas period, and, though new applicants have very little chance of obtaining a connection just now, it is hoped that the committee will be able to satisfy all present users.

The North Staffordshire Tramways.—On Wednesday, a meeting of representatives of Stoke, Hanley, Burslem, Longton, and Fenton, convened by the Stoke Corporation, was held at Stoke-on Trent for the purpose of discussing matters in connection with the North Staffordshire tramways. The meeting eventually passed the following resolution: "That this meeting is of opinion that the various local authorities within the district of the tramways company should combine in opposing the clause proposed to be inserted in the agreement with respect to the purchase of the electrical equipment of the company, and that the clause should be altered so as to read that in the event of the option of purchase being exercised the sum to be paid should be ascertained by arbitration."

Kingswood (Bristol).—A draft of the proposals of the Great Western Electric Light and Power Company, who are about to apply for powers to supply public and private electric light in the Kingswood district, has been brought before the Urban Council. Mr. Wilshire said he did not think they could possibly have a much worse plant than that now used for the electric light. Mr. Newman considered that the negotiations that had been going on as to the lighting of the district had not been over-expeditious. He had intended asking for an extension of the light in Church-road, where it was very much needed. The question was deferred until the next Council meeting, when the proposals of the new company to supply the whole of the area covered by the Council with their system of electric lighting will be considered.

Yarmouth.—The surveyor's monthly report as to electric lighting is again satisfactory. Since the last meeting applications have been received from 15 new customers for 580 lamps, making the total number of customers 135 for 6,369 lamps The income for November amounted to £308. 8s, and the expenditure to £164. 14s. 2d. Thus, the Council had earned £143. 13s. 10d. beyond the cost of the production of the light. From this have to be deducted repayment of capital and interest, rates and taxes, and depreciation—estimated at £90 in all To meet a very general request, the Council have instructed the surveyor to arrange as early as possible for supplying customers continuously. The Council have resolved to increase the salary of Mr. Ranken, who holds the post of chief engineer at the electric lighting station, to £200 a year.

Dynamo Brushes.—We have received from Messrs. F. W. Potter and Co., wire-weavers, wire-workers, etc, of Phipp-street, Great Eastern-street, London, E.C., a price list of their "Dovetail" copper gauze brush for dynamos and motors (Soar's patent) The "Dovetail" brush is made of copper wire gauze, so folded that the part intended to face the commutator consists of plain layers of gauze to the extent of about one half of the thickness of the brush, backed by about an equal quantity of gauze folded or corrugated at or nearly at a right angle to the plain layers, or without the plain layers of gauze; and the degree of stiffness given to the brush can be varied from the great flexibility of an ordinary wire gauze brush to almost the rigidity of metal. As to the advantages of this brush one customer of Messrs. Potter wrote that in his opinion, "It is the 'Dovetail' first, the others nowhere."

Liverpool.—"Regret" writes to the *Courier*: "How much longer will it be before the thoroughfares of Liverpool will be lighted by electricity? The municipal authorities seem inclined to sit down and worship the work of their illustrious predecessors, like the Chinaman. Meantime the 'great sea city' remains with stunted streets, lighted in the most ancient manner possible, and a pierhead graced by minute public-houses." The first experiment in the lighting of the Prince's landing-stage by electricity was made the other evening. Six arc lamps were erected upon temporary posts at equal distances from the office of the river police to the north end. The lights were turned on for a couple of hours, and were inspected by the dock engineer, the general manager, and a few members of the Dock Board. If the Board adopt the electric light—as no doubt they will—the illumination of the stage will then leave nothing to be desired.

Beckermet (Cumberland).—The Lighting Committee have reported to a parish meeting on the lighting of the village. The committee had obtained estimates for lighting by oil, which, with maintenance expenses, would involve a rate of from 3¾d to 2¾d. in the pound. As water power was available, they had also obtained an estimate from an electric light firm, according to which the plant would cost about £39, equivalent to a 2¾d. rate. There would be only 10 lamps of 16 c p. each, instead of 12 oil lamps, and the wires would be placed on posts, and, of course, they could not be at any time used for house lighting. It had been suggested by the committee that a practical man be asked to come to the village and give an estimate of what the electric light would cost with wires underground, and with sufficient power to supply any houses that might require it. The meeting after some discussion, decided not to adopt the Lighting Act.

Taunton.—The Electric Lighting Committee of the Town Council have reported that, in consequence of an additional 120 lamps being installed in South-street, it would be necessary to provide a new transforming station at East Gate in accordance with the estimate adopted by the Council at their meeting held on September 11, 1894. The Local Government Board had sanctioned the borrowing of the money. The committee therefore asked the Council to authorise them to take the necessary steps for carrying out the works and to obtain tenders for two new transformers Dr. Fleming visited Taunton on the 4th inst. for the purpose of inspecting and testing the switchboard supplied by Messrs. Newton, and also the engine and alternator supplied by the British Thomson-Houston, Limited. He met the committee on the 5th, and reported that the result of his testing was satisfactory. He promised a written report in a few days The committee's report was adopted.

Harrogate.—Mr. W. F. B. Clerke, C.E., has held the Local Government Board enquiry into the application of the Town Council for sanction to borrow £33,700 including £20,500 under the Electric Lighting Act for building, plant, etc In answer to the inspector, the Town Clerk said that the cost of obtaining the electric lighting order was £264, and they had spent in deputations and fees £750 The population of the borough was from 16,500 to 17,000, and it had practically doubled itself in 20 years. The ratable value was £109,000, and the total debt was £194,460. The Mayor urged the early and favourable reply of the Local Government Board in reference to the loans, as they were desirous of opening a portion of the new baths next season, and strongly desired the electric lighting installation to be in full working order by that time. The Inspector said that he should submit his report in about 10 days, and he should mention to the Board that the Town Council were anxious for an early decision.

Newington (London).—The report of the General Purposes Committee in respect to electric lighting has been submitted to the Vestry. The report recommends the Vestry to oppose the granting of a provisional order to the County of London and Brush Provincial Company to supply the parish with electricity for public and private purposes In the discussion which ensued Mr Davies reminded the Vestry that the adoption of an electric lighting scheme would involve an expenditure of many thousands of pounds, and said he did not believe in the municipalisation of everything. On the other hand, Mr. Westcott contended that as other parishes smaller than those of Newington had made electric lighting pay he did not see why they should not, and he urged that they should not commit the blunders of Leeds and Liverpool, which had been forced to buy out at a tremendous premium the companies to whom they had surrendered their provisional orders. The recommendation of the committee was then carried, and it was decided to apply to the Board of Trade for a provisional order.

Blackrock (Dublin).—The township engineer has submitted a report in reference to the state in which the roads were left by the contractors for the Main Drainage Board and the contractors for the electric tramway company. He stated that the Drainage Board left the roads at Seaforth-parade, Idrone-terrace, Tobernea-terrace, and Seapoint-terrace in a very rough condition, and although a little improvement had been attempted in some directions much remained to be done. The contractor had repaired the crossings at Alma-road, but not in a workmanlike manner. In reference to the tramway contracts, it was alleged that owing to the alterations of the levels of the roads all the crossings, with the exception of two, had been disturbed. Stones had been taken up and never replaced, the crossings left too high on one side and too low on the other, and in some places altogether too low. The cable trench throughout had never been properly rammed or finished, and was still in several places too high. The tramway officials had from time to time promised to have these matters attended to, but up to the present nothing has been done in reference to the crossings and very little as regards the cable trench.

Brighton.—The Works Committee of the Brighton Town Council have received a fresh application from the General Post Office with reference to the proposal to carry a line of overhead wires across Ship-street. It is pointed out that this is part of a work of national importance, in which such a town as Brighton must be considerably interested, inasmuch as the wires are intended to form a part of the "backbone" system of trunk telephones which the Department is now engaged in establishing in pursuance of the policy sanctioned by Parliament in the Telegraph Act of 1892. It was resolved by the committee "that

Digitized by Google

under the exceptional circumstances of the case, the permission asked for be granted, subject to the conditions mentioned in the application." The General Purposes Committee of the Brighton Town Council have resolved, on an application on behalf of the Brighton and Rottingdean Electric Tramroad Company, that the company shall be released from the requirement that they shall provide sureties to join in the bond for £1,000 to be given by the company for the removal of the poles about to be erected by them for carrying electric cables, and also that security for the removal of the railway in certain contingencies shall not be included in the bond.

Cardiff.—The Lighting Committee have received a letter from Mr. Walter Cook, hon secretary for the coming Cardiff Exhibition, to the effect that the Exhibition Executive Council had decided not to accept the offer of the Lighting Committee for electric light supply, because the total cost would be greater than that of a separate installation. The offer was to supply the exhibition with all the current up to 100 000 units for £1,400. The Chairman said special endeavours had been made to get a supply for the exhibition, and they had made the offer that had been read. But they had to put themselves in the position of guaranteeing the current by the 10th of April. The exhibition would be opened on May 1, but the electric light was wanted before that date, so that the necessary preparations might be made. There were, however, so many extensions and so many orders that he took upon himself to say that owing to the necessities of the ordinary town supply the committee could not guarantee the current by April 10. If there were not the hurry and rush of supplying the exhibition, they would have time to complete the town supply. Major Sloper, Mr. Wentworth Price, and Mr. Williams attended on behalf of the Royal Arcade Company and discussed the question of lighting the arcade by electricity. It was stated that the Arcade Company were prepared to hand over the arcade to be a public thoroughfare on certain conditions, but ultimately the whole question was referred to the Public Works Committee.

Electric Lighting in London.—The Board of Trade have received applications from the Battersea and Newington Vestries asking for provisional orders empowering them to supply electricity within the area of their respective jurisdictions The Board have also received an application from the City of London and Brush Provincial Electric Light Company asking for powers to supply electricity within the district of the St. Saviour's District Board of Works and the parishes of St. Mary (Newington), St. Mary (Lambeth), St. Giles (Camberwell), and St. Mary (Battersea). The time for lodging objections to these applications will expire on January 15, 1896. At a meeting of the City Corporation, Mr. T. H Brooke Hitching asked the chairman of the Commission whether he was aware that the City of London Electric Lighting Company were charging 8d. per Board of Trade unit, while other districts of the Metropolis were supplying light at 6d. ; whether there was any provision made for the purchase of the company's undertaking on an equitable basis, and what notice of purchase was required. Mr H J. Gordon, the chairman of the Commission, said it had granted a concession to the company for public lighting for 21 years, with the option of purchase at the end of seven or fourteen years, the period to date when the contract was completed. As regards private lighting, a similar concession of 21 years had been granted, and the fact was that the Commission had very little control over the company's private lighting.

Hampstead (London) —The Lighting Committee of the Vestry have reported that they had carefully considered the present state and working of the public arc lamps in Finchley-road, and had interviewed Mr. Alexander Siemens on the subject. and were of opinion that a thorough and exhaustive trial should be given to the lamps ; and, further, that, with a view to accomplishing that object, they had asked Messrs. Siemens Bros. to take over the entire charge of the whole of the public arc lamps in Finchley-road for a period of eight weeks and had instructed the engineer to report, on behalf of the Vestry, on the trial at the termination thereof.—Approved. (See "Results of Tenders") The present basis on which meter rents are charged to the private consumers of electric light having been found unsatisfactory, a new scale of charges was decided upon, varying from 2s. 6d. per quarter upwards. It was decided to lay mains for private electric lighting in Lancaster-road and Compayne-gardens. The chief engineer was empowered to obtain materials etc , required immediately, at a cost of £250, and the Lighting Committee were authorised to obtain a further supply, if necessary, before the next Vestry meeting. Mr. Farmer asked a question referring to the proposal to light High-road, Kilburn, by electricity. The Chairman expressed the opinion that it would be very unwise for such a question to be answered whilst the system adopted by the Vestry in the Finchley-road was on trial. The Vestry decided to pay the account of Mr. W. H. Preece, amounting to £150 for preparing plan and detailed estimate of the extension of high and low pressure mains, and arc lighting plant and mains to High road, Kilburn, and West End-lane.

Blackpool.—The *Blackpool Gazette* of December 13 says: "If all we hear be true, Monday's meeting of the Electric Lighting Committee was about the liveliest of all the lively gatherings that have been held from time to time in connection with the Blackpool Town Council. In accordance with the instructions of the committee, Mr. J. Hesketh submitted a report upon the electricity works, in which he recommended that extensions, which would have the effect of doubling the capacity of the works, should be put in hand at once. He pointed out that the works were already overloaded, and he would not be answerable for what might happen unless the plant was increased. In order that any new machinery might be working by Whitsuntide next, it would be necessary to give out orders in the early part of January, and therefore he impressed upon the committee the necessity of urgency. The discussion upon Mr. Hesketh's report was nothing else than a series of scenes. Several members of the Council manifested an astonishing amount of feeling on the question, the Mayor and Councillor Ward being especially antagonistic to the electrical engineer's report. Eventually matters rose to such a pitch that Alderman Bickerstaffe (who was presiding) announced his immediate resignation of the chairmanship of the committee. No decision had been arrived at up to this point, and the meeting forthwith broke up in disorder. We understand that another meeting of the committee is called for this (Friday) afternoon, in order to appoint a chairman. In a matter of so much importance as the future of the electricity works undoubtedly is, we trust that great unanimity will henceforth prevail."

New London Mains.—At Tuesday's meeting of the London County Council the Highways Committee reported that they had (1) considered two notices, dated November 28 and 30, 1895, respectively, from the House-to House Electric Light Supply Company, of intention to lay low-tension mains in (*a*) Earl's Court-square and (*b*) across Earl's Court road They saw no objection to the works proposed. (2) Considered a notice, dated December 3, 1895, from the Westminster Electric Supply Corporation, of intention to lay mains across Rochester-row and Francis-street, and in and across Emery-hill-street. The proposed works were of the usual character. (3) That the Vestry of St Pancras have given three notices, dated November 28, December 3 and 9, 1895, respectively, of intention, under the provisions of the St. Pancras Electric Lighting Order, 1883, to lay mains (*a*) across Pancras-road, (*b*) in Kentish Town-road, and (*c*) in Albert road. The proposed works were unobjectionable (4) They had also considered a notice dated December 5, 1895, from the Charing Cross and Strand Electricity Supply Corporation, of intention to lay mains in and across Whitehall-place. The proposed works were unobjectionable. (5) That a further notice, dated December 6, 1895, had been received from the Charing Cross and Strand Electricity Supply Corporation, of intention to lay mains from the Charing Cross Bridge of the South Eastern Railway Company across and along a part of the Victoria-embankment and along Villiers-street, Duke street, and John-street, across the Strand, and along Bull inn-court to the company's station there. In the opinion of the committee the route proposed is not the best that might have been chosen, and the proposals in the notice are in other respects not quite satisfactory. They have directed the Council's engineer to communicate with the company with a view to the proposal being amended.

Electric Railways in London.—The Vestry of St. Mary Woolnoth have instructed their clerk to take the necessary steps to oppose the new Bill of the electric railway company. The Lord Mayor, as the leading parishioner, will be invited to co-operate with the movement. At the last meeting of the City Commission of Sewers a report was brought up from the Streets Committee relative to the Central London railways and subways, and submitting for approval amended plans of the staircases at the corner of Princes-street (by the Union Bank), Queen Victoria-street (near the Poultry), and by the Mansion House, subject to the works being carried out to the satisfaction of the Commissioners and without prejudice to the rights reserved generally by the Commission in 1893 to alter the position of any staircase or to modify the details in any particular. They recommended that before commencing the works for the purpose of the central station, subways, and approaches, the Central London Railway Company be required to deposit a sum equal to the estimated total cost of the works to ensure their due completion. The effect of the alterations was that there would be separate staircases for the up and down traffic at Princes-street and the Mansion House corners, and that at the Poultry corner the staircase would be partitioned in the middle so that the traffic would be divided. The changes would involve the projection of the present foot pavement at Princes-street by over 6ft., but the refuge in the roadway would be reduced considerably. The roadway itself would still be 26ft wide. Mr. A. J. Hollington said the improvement at the Princes-street corner had only been recently carried out at an enormous cost, and now they proposed to give up 6ft. of the pavement to a railway company. He thought the company should purchase the property, and he moved that the report be referred back for reconsideration. Mr. Ross, the engineer, said the land was estimated at between £30 and £40 per foot. Mr. A. C. Morton said the subways would be of enormous public benefit, and the company were constructing them free of expense. The report was eventually carried.

London County Council.—At Tuesday's meeting the Highways Committee recommended that they be authorised to visit Bristol during the Christmas vacation for the purpose of inspecting the system of electric traction in operation upon the tramways there. They also recommended, "that subject to the condition that at a later stage further plans, giving full particulars of the arrangements for the accommodation of the public, be submitted to the Council, the Council do agree so far only as relates to the positions of the shafts and of the entrance and exits to the plans (submitted by the Central London Railway Company, under the provisions of its Act of 1891) of the proposed stations at Queen's-road, Oxford-circus, and Chancery-lane." The engineers of the company have agreed to the modifications required under the Council's resolution of December 3, in the plans of the stations at Holland-park, Notting Hill-gate, Marble Arch, Tottenham Court road, and Bloomsbury. Further, "that the Parliamentary Committee be requested to approach the Government with a view to the reintroduction, in

Digitized by Google

the session of 1896, of the Bill to amend the law with respect to the use of locomotives on highways." Further, "that the Board of Trade be informed that, having regard to the decision upon the appeal with reference to the construction of transformer chambers in St. Luke's and Clerkenwell, the Council is of opinion that no enquiry is necessary in the matter of the appeal of the County of London and Brush Provincial Electric Lighting Company as to transformer-chambers in the Wandsworth district." The Theatres and Music Halls Committee reported that some time ago they instructed the engineer to inspect the electric lighting installations in all the places of public entertainment in London which are licensed by the Lord Chamberlain and the Council. The engineer asks that he may be authorised to employ an additional assistant in order that the work may be carried out as quickly as possible, and as this inspection is in the opinion of the committee urgently necessary in the public interest, they recommended "that the engineer be authorised to employ an assistant at the wages of £4. 4s. per week to assist in getting particulars of and testing the electric lighting installations in places of public entertainment."

Southport.—The minutes of the Electricity Committee of the Corporation contained the following: "Resolved, that is desirable that the following streets should be lighted with electricity—viz., Lord street, from Coronation-walk to Duke-street, and from Seabank-road to Leicester-street, Eastbank-street, Chapel street, London street, and Neville-street." Councillor Hesford moved the adoption of the minutes of the committee. He called attention to the paragraph with reference to the suggested lighting by electricity of Lord-street from Coronation-walk to Duke-street, etc. The committee had been urged by members of the Council and others to light the part of Lord-street from Coronation-walk to Duke-street. He explained that the Electricity Committee could not work on the same lines with reference to lighting the town as the Gas Committee, who could go on with the work of lighting that they considered desirable without approaching the Council. They had not yet been in a position to present to the Council a report of the full year's working of the electric light, but they would do so at the next meeting, and the reason they were approaching the Council at that meeting was because they wished to ascertain whether they were in favour of any further extension whatever of the public lighting by electricity during the next lighting season. It was not the intention of the committee to increase the lighting during the present lighting season. It was merely a preparatory resolution to enable them to furnish themselves with apparatus and appliances to meet the Council's wish should the Council desire any further extension. There were at present 40 lamps; the Halls Committee had now taken two more for the front of the Municipal Buildings, thus making a total of 42 lamps now in operation. Plant had been laid down for supplying electricity to 100 lamps, so there were 58 lamps still undeveloped. Roughly speaking, it would require £1 500 to £2,000 to completely utilise the power of the cables by increasing the number of lamps to 100. The report to be presented at the next Council meeting would include a full return of the borrowing powers, the amount of the capital expended, the revenue and the expenditure. They did not anticipate a loss, and they did not anticipate a profit on the working of the electric light for the year; either way the balance would be represented by about £50. Councillor T. Jones seconded the minutes. Councillor Ashton pointed out that Councillor Travis had not alluded to the dead capital of the Gas Committee. He thought they ought to wait until they knew what the profits of the electricity would be. He should vote for the paragraph being referred back until they had the financial statement before them. The minutes were adopted with the exception of the clause in question.

Electric Tramcars in the Black Country.—The *Midland Counties Express* says: "Once more the question of the continuation of the electric trams in the Wednesbury, Darlaston, Walsall, and Bloxwich districts has arisen. It seems but a few months since the public were wondering whether they would cease to run or not, and now there is the same anxiety and unsettledness. It will be seen from the report of the Walsall Town Council held on Monday afternoon, that a letter was read from the secretary to the Electric Construction Company, Limited, Bushbury, stating that they had given notice to the South Staffordshire Tramway Company that they could not continue to run the electric portion of the tramway company's lines on the present terms beyond the end of the month. It may be stated that the company provide the motive power, the cars and drivers and own the generating station and machinery. The matter is one of great importance, and the travelling public will hope that satisfactory arrangements will be come to before the expiration of the time stated. Whether this will be so or not is at present a subject for speculation. Upon enquiring at the offices of the Electric Construction Company on Tuesday morning, we were informed that there was nothing new to be obtained. The company wish it to be distinctly understood that they have no desire to stop running the electric cars if arrangements can be come to for their continuation, and that it is not they who are putting obstacles in the way. It will be remembered that on the last occasion the Electric Construction Company undertook to run the electric cars at a certain price per mile, the roads to be kept in a satisfactory state by the tramway company. The Construction Company now state that the roads are not in a satisfactory condition; indeed, they are so bad as to cause unnecessary wear and tear to the cars and machinery, thus increasing to the electric company the cost per mile of running the cars. Moreover, they assert that the tramway company for some time have been charged less than was set down in the agreement. They feel that they cannot continue to work the cars as things are at present, hence the month's notice which has been given to the tramway company. We understand that the Construction Company want the roads put in good working order, so that no unnecessary damage shall be done to their cars and machinery, and the rate of payment per mile in accordance to the agreement to which we have alluded. A considerable time would be required to do the necessary repairs to the roads, but the Construction Company are prepared to come to terms for the cars to be kept running, and to make an arrangement for their continuance afterwards. We are assured that unless a satisfactory arrangement be come to at the end of the month, the electric cars will cease to run. The stoppage of the cars will be an enormous public inconvenience, and the public convenience should be first considered."

Edinburgh—It is understood that the Edinburgh Town Council propose to reduce the cost of electricity for lighting purposes from 6d. to 5d. per unit, to take £2 per annum off the cost of each public lamp, and to relieve consumers of the meter rent. Prof. Kennedy, we believe, has made a calculation that during the year from April 1896, to April, 1897 the city will sell about 1,035,000 units to private consumers, and receive at present rates and discounts about £23,000. The number of units mentioned corresponds to about 1,220,000 generated. Besides this the Corporation will have to generate 480,000 units for arc lighting, for which they will receive about £5,000. The total income will thus be £28 000, and the total number of units generated in the station about 1 700,000. Station costs will be about £6,670. The present standing charges amount to £8,500 a year, and, with charges for wages, material, a percentage on additional capital, etc., a total of £18,000 for standing charges is reached. There is thus a gross estimated profit of £8 000, according to Prof. Kennedy, out of which allowance has to be made for depreciation of plant—say, from £1,000 to £2,000. The proposed reduction in price would reduce the income £4 820, against the balance of £8,000, less depreciation. Prof. Kennedy thinks, after a year's working, that the Corporation would be quite safe in making the reduction According to the best tests, it is considered that the price proposed to be charged will be, light for light, equal to the Edinburgh gas. The Plans and Works Committee of the Town Council have recommended, on the motion of Bailie Gulland, that the Tron Church and Register House clocks should be lighted by electricity. The lighting of the City Chambers and the Royal Exchange by electricity was also considered, and a report is to be submitted to the next meeting of the committee by the city superintendent. The Town Council have considered *seriatim* the clauses of the Edinburgh Improvement, Municipal, Police, and Tramways Bill. Clause 27 gives power to the Corporation to use mechanical and electric power on the tramways. Sir James Russell said they would be sure to have the opposition of the telephone companies to the word "electric." The Lord Provost: Why? Sir James Russell: We won't very soon be able to walk the streets for the telephone monopoly. The Lord Provost: We'll have it in. The Council subsequently passed the Electric Lighting Committee's report recommending an extension of plant at the electric lighting station. Sir James Russell remarked that they had every reason to look forward to the future with hope. Before, however, making the reductions suggested by Mr. Mackenzie he should have to make a very careful enquiry into the figures. Treasurer M'Crae complained that the tearing up of the streets had been unsatisfactorily repaired, and Mr. J. C. Dunlop, convener of the Streets and Buildings Committee, also urged that in future extensions due care should be taken to relieve his committee from responsibility for unsatisfactory work, for which the public blamed them. The Lord Provost promised Mr. Dunlop and his colleagues every possible relief in the future.

Swansea.—Members of the Electric Lighting Committee of the Swansea Corporation state that the work preparatory to lighting the central area of the town will be actively proceeded with next month The gas company are experimenting publicly with incandescent gaslights A special meeting of the Swansea County Council was held on Monday for the purpose of considering the questions of electric lighting, electric tramways, and the erection of a dust destructor. The Mayor (Alderman Bradford) presided. The committee presented their report, which stated that detailed plans of the proposed electrical works had been prepared by the consulting engineer (Mr. Manville), and had been forwarded to the Local Government Board, and that the committee had engaged the services of Mr. William John Rees for the acquisition of the necessary land required for this purpose. As regards the question of supplying electrical power for the tramways, the mayor and the town clerk have had several interviews with the directors of the tramways company. Mr. Waller also attended a meeting of the committee on the 11th inst, on behalf of the tramway company and as a result it is now recommended that the price at which the Corporation would be prepared to supply electrical power to the tramways be as follows: (1) the company to undertake to purchase a minimum of 400 000 units per annum at 2d. per unit; (2) if the minimum taken be 600.000 units per annum, the price to be 1½d. per unit; (3) if the minimum taken be 750,000 units per annum, the price to be 1¼d. per unit. The committee recommend that the agreement be approved, and the draft forwarded to the company for their consideration. Mr. George Hopkins, C.E., has been retained to report upon the proposed terms of purchase of the tramways. Mr. Martin, in moving the adoption, said that was the last link in the threefold scheme by which they expected to let Swansea for once stand in the front of other towns of the United Kingdom. One part of the scheme was that adopted some time ago by the Council of destroying its

Digitized by Google

refuse by burning it, and thus avoid any possibility of its being a nuisance to any part of the town or district. By destroying the refuse by quick combustion they hoped to be able to save the greater part of the heat generated by that combustion. They hoped to utilise that waste to generate steam, that steam they also proposed utilising to drive machinery, by that machinery generating electricity, and to supply the town with electric light and electric power. They had also come to terms with the Swansea Improvements and Tramway Company for the acquisition of their tramways within the borough limits Those terms were subject to a lease being given to the company for 21 years. At the request of Mr. Daniel, Mr. Martin went on to repeat the details of the terms entered into with the tramway company, which have been already published. If the tramway company took the minimum of 400,000 units, it would come to £3,333. 6s. 8d., which would pay all the cost of their station if they barred the interest on the sinking fund. So far as Swansea was concerned, the threefold scheme would fit in such a way that they would be able to offer electricity at a profit for electric lighting to their ratepayers, business men, and residents at a price which gas could not touch, and that was not so at any other town in the kingdom. Other towns had heard of what Swansea was doing, and had already made haste to follow Swansea's example. No sooner did the chairman of the Electric Lighting Committee at Portsmouth hear of it than he took the matter up, with the result that the authorities of that town are now going in for the same scheme. The report was carried.

PROVISIONAL PATENTS, 1895.

DECEMBER 9.

23564. **Improvements in alloys applicable for solders, electrical safety plugs, fire alarms, heat indicators, and the like.** Alexander Schanschieff, 77, Chancery-lane, London.

DECEMBER 10.

23653. **Improvements in or connected with electric tram or railway systems.** Herbert Allen and Oliver Peard, 55, Chancery-lane, London.

23658. **Switches for underground electric railways.** Alfred Rosenholz and Henry Edward Poehlman, 60, Queen Victoria-street, London. (Complete specification.)

23670. **Improvements in methods of lighting by electric arc lamps.** Paul Henri Guérin, 65, Chancery-lane, London.

23692. **Improvements in electrically-operated apparatus for dental purposes.** Oscar Henry Pieper and Alphonse Ferdinand Pieper, 52, Chancery-lane, London. (Complete specification.)

DECEMBER 12.

23811. **Improvements in or connected with dynamo-electric generators.** Willem de Graaff, 15, Water-street, Liverpool.

23841. **An electrical system and apparatus for synchronously indicating at one or more distant points the distance registered by a ship's log.** Howard George Brain, 1, Furnival-street, Holborn, London.

23844. **Improvements in mooring swivels or apparatus for use in connection with lightships, guardships, or other floating bodies that are connected with the shore by electric or telegraphic cables.** Edward Shore, 6, Lord-street, Liverpool.

23852. **Diaphragms or partitions for electrolytic purposes formed of carbonates of alkaline earths.** Samuel Sidney Bromhead, 97, Newgate-street, London. (La Société Anonyme des Anciennes Salines domaniales de l'Est Actien-Gesellschaft, Germany.) (Complete specification.)

23855. **Improvements in electrical switches.** The Edison and Swan United Electric Light Company, Limited, and Charles Faraday Proctor, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23857. **New or improved system of telegraphy and telephony.** Richard Joseph Crowley, *Invention* Office, Mitre-court, Fleet-street, London.

23865. **Improvements in or relating to thermo-electric generators.** Alfred Julius Boult, 323, High Holborn, London. (A. Wunderlich, Belgium.) (Complete specification.)

DECEMBER 13.

23892. **Improved means for conveying current to electric motor cars on streets or roadways.** William John McCaw, 62, St. Vincent-street, Glasgow.

23894. **Improvement in telephones and telephone switches or line selectors.** Charles Leigh Clarke and William Paul Theermann, 7, South-parade, Manchester.

23922. **Improved means for compensating variations of load at electrical stations.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

23943. **Improvements in the lighting of streets and the like by incandescent electric lamps.** Robert Cornelius Quin and Henry Reason, 31, High Holborn, London.

23952. **Improvements in and relating to electric batteries.** Hartley Fewson, *Invention* Office, Mitre-court, Fleet-street, London.

DECEMBER 14.

23976. **Improvements in ball joint fittings to be used for electric lighting.** Joseph John Perkins Barker and James Stephen Blackwell, 19, Bowling Green-street, Leicester.

23994. **Dynamo machines for producing alternating electric currents of low tension.** Arthur George Adams, 35, Ampthill-street, Bedford.

24020. **Improvements in safety-fuse devices for electrical installations.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

24021. **Improvements in switches for connecting two or more electromotors.** Siemens Bros. and Co., Limited, and Albert Thomas Bartlett, 28, Southampton-buildings, Chancery-lane, London.

24037. **Electric programme or bell-ringing clock.** Leonidas Hamline Watters, 89, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1890.

13260. **Distributing electricity.** Dobrowolsky and another. (Second edition.)

NOTES.

The Queen and the Electric Light.—A short time ago we printed a note headed "The Queen *v.* the Electric Light." Her Gracious Majesty was reported to be as much opposed to "the" illuminant as the Empress of Austria or Harry Furniss is. We are glad to be now able to substitute the conjunction for the preposition. Balmoral Castle is to be lighted by electricity, according to a Scotch newspaper. The motive power is to be taken, not from the Dee, but from the Gelder. In the first instance the electric light will be fitted up in the ballroom only, but ultimately, no doubt, all the rooms of the Castle will be supplied with the current. It is stated that the expenditure contemplated is about £1,400.

Light Railways.—Mr. Ritchie, P.M., President of the Board of Trade, has written to Mr. Wallis Davies, the secretary of the Light Railways Association of Great Britain, stating that he will be happy to receive a deputation on behalf of the association on Thursday, February 13, at noon. The committee appointed will sit during the month of January, and consists of the Duke of Sutherland, Lord Winchilsea, Lord Clinton, Lord Sherbourne, Earl Russell, the Earl of Warwick, Sir Albert K. Rollit, M.P., Sir Alfred Hickman, M.P., Sir John T. Hibbert, Sir John Puleston, Sir Douglas Fox, Sir James Szlumper, the Hon. C. H. Strutt, M.P., and other members of Parliament representing various parts of the country, as well as representatives of local authorities throughout Great Britain.

Aluminium.—From *Comptes Rendus* (December 2) it appears that M. Henri Moissan has been investigating the contradictory results which experimenters have arrived at with reference to some of the properties of aluminium. M. Moissan ascribes these to the fact that all commercial samples of this metal contain impurities. The effects of nitrogen and carbon he has already dealt with, and having had occasion to analyse samples of aluminium from the works at La Praz (France), Neuhausen (Switzerland), and Pittsburg (United States), he has now discovered a new impurity—namely, sodium. This may be present to the extent of from ·1 to ·3 per cent., and renders the aluminium liable to be slowly attacked by water. The presence of a small quantity of sodium also completely alters the character of aluminium alloys.

Responsibility for Electric Death.—A short time ago two persons were unfortunately killed by coming in contact with a wire belonging to the Elektrizitäts-Gesellschaft in Limburg (Lahn) which had become detached from its place in a storm. The manager of the company was eventually put upon his trial for manslaughter, negligence being alleged against him. He has, however, now been acquitted. He affirmed himself, and was supported by two experts in his opinion, that it had not hitherto been known that a current of under 1,000 volts could kill a man; and the judges were not in a position to refute this argument. It was shown that the pressure of the current on the day in question did not exceed 800 volts. The said judges would doubtless find the recent Board of Trade discussion on high pressures interesting reading.

Foreign Royalty at the Arsenal.—Prince Nicholas of Greece paid a visit to the Royal Arsenal, Woolwich, the other day, and was received at the office of the Director-General of Ordnance Factories by Dr. Anderson and the heads of departments. Prince Nicholas proceeded on the Arsenal railway to the proof butts, where he witnessed the firing of heavy guns, both with cordite and black powder. He then visited the torpedo factory, where the various operations of manufacturing Whitehead torpedoes were shown, after which he saw the filling of small-arm cartridges and the manufacture of cartridge cases. At the South Boring Mill he witnessed the operations of winding wire of guns, the turning and boring of large forgings, and the working of the 40-ton hammer. In the Royal Carriage Department he saw the new 9·2in. gun mountings, worked by electricity, for the new cruisers "Powerful" and "Terrible."

The Metric System.—A deputation of six members of the British Chamber of Commerce in Paris, accompanied by representatives of several important English newspapers, were present the other morning in Paris at two successive lectures on the metric system. Both lectures were original and were delivered by children under 12 years of age, one in a boys' school and the other in a girls' school. Mr. Pilter, speaking on behalf of the British Chamber of Commerce, thanked the municipality of Paris for having once more given an opportunity for the appreciation of the admirable simplicity of the French metric system. He added: "I hope and I am sure that the British representatives who have heard these lectures will give an account of these meetings, and I am convinced that the account which they will give of them will advance the adoption of the metric system in our country. We hope that, in view of all the facilities which it offers, our country will soon be endowed with the metric system, which the whole world owes to the French nation, and for which it must feel eternally grateful to her."

Gas v. Electric Light.—In continuation of this subject (see p. 699) a correspondent would like us to have his opinion of the incandescent gaslight. We are always willing to open our columns to the ventilation of grievances in which our readers are professionally interested, so we readily give space to this correspondent's wail of complaint. He says: "I had two of these incandescent gas lamps fixed in a sitting-room at the beginning of the year, with the intention, if I liked them, of having them fitted all over my house. I was immensely pleased with the light they gave, but my pleasure was soon turned to dismay when I noticed that a most offensive smell was given off from them when they were turned down to the by-pass. The workman who fitted the lamps from the local representative of the company came repeatedly to endeavour to remedy this defect, but without success. The smell was so offensive that I was compelled to discontinue using the by-pass and to turn the light off every time it was done with. This of course necessitated relighting the burner each time it was required, and, as those using the lamps must be aware, the lighting of them is rather an awkward matter, especially for servants, as the burner lights with an explosion, and this in course of time shatters the mantles." And everyone knows what "shattering the mantle" means to the poor gas consumer.

Personal.—Dr. R. Mullineux Walmsley, lately professor of physics and electrical engineering in the Heriot-Watt College, Edinburgh, and recently appointed principal of the Northampton Institute, London, was, on Friday, the 20th inst., made the recipient of a handsome gift of books from his past and present students of the college. The presentation, which consisted of an edition of Scott's works and Ruskin's "Stones of Venice," was made by Mr. C. A. Henderson, one of the day students. Principal Ogilvie, who presided, remarked that they met under very mixed feelings. They felt very sorry at parting with Dr. Walmsley, but warmly congratulated him upon his new appointment. Many of them had had an acquaintance with him extending over a period of six years, and during that time the progress of the college had steadily extended. When Dr. Walmsley came the institution was at a stage when a strong mind and a master hand were required, and

Digitized by Google

the governors were to be congratulated upon their selection of Dr. Walmsley, because in his hands the department over which he presided had been successfully carried on. The staff were fortunate, because as a fellow-worker he was capable and willing to assist in all the general work of the college, and thus lightened the work of all. The students were also fortunate in having Dr. Walmsley, because he had had the laboratory so well equipped for all those who belonged to the various paths of service in which electricity and physics generally formed an essential feature.

East London Trades, Industries, and Arts Exhibition.—We have received a prospectus and schedule of prizes of an exhibition which is to be held next June at the People's Palace under the honorary presidency of H.R.H. the Prince of Wales, and in which electricity will play a more or less important part. There is a very influential list of vice-presidents, a thoroughly businesslike executive committee, and a very extended general committee of sympathisers. The salient features of the exhibition, in addition to the usual industrial exhibits that may be expected from manufacturing firms, are: (1) a special section for the work of individual craftsmen; (2) a section for the work of apprentices and of students at the various London polytechnics (the most important of these institutions all over London are expected to take part in the exhibition); (3) a women's section. Provision will be made for a continuous series of concerts and other entertainments during the exhibition. Mr. Edmund H. Lloyd, of the Military, Naval, and Chicago Exhibitions, has been engaged as manager of the exhibition. The committee desire to get together a guarantee fund of from £8,000 to £10,000, and their exertions during the last eight months have already brought them in more than £6,000. They have also received donations towards the objects of the exhibition to the amount of £1,000. They hope that by bringing the matter forward publicly the objects of the exhibition will become known to those to whom it is intended to benefit, and that the remaining £2,000 or £3,000 will soon be collected, either in the form of guarantees or subscriptions.

Alternate-Current Transformers.—The following is a synopsis of the Society of Arts Cantor lectures on "Alternate-Current Transformers," which are to be delivered by Dr. J. A. Fleming, F.R.S.: January 20—Lecture I.—The Action of the Transformer: Real and imaginary transformers—Transformer diagrams—Alternate-current curve tracing—Various forms of curve tracers—Discussion of transformer diagrams—The harmonic analysis of diagrams—The curves of induction and hysteresis—Magnetic leakage—Core and copper losses—Effect of variation of form of the E.M.F. curve on core losses—Variation of core losses with temperature—The power factor. January 27—Lecture II—The Construction of the Transformer: The core—Sheet-iron stampings—Building the core—Prevention of core losses—Selection of iron—The coils—Coil winding—Insulation of coils and core—The case—Ventilation and surface radiation—The terminals—Primary and secondary fuses and switches—Sizes and forms of transformers in practice—Open and closed circuit transformers. February 3.—Lecture III.—The Testing of Transformers: The measurement of the power taken up in an inductive circuit—The theory of the wattmeter—The construction and use of the alternate-current wattmeter—Various methods of measuring alternating-current power—The testing of transformers—Testing by curve tracing—Testing by the wattmeter—Differential testing—Practical tests in the sub-station and workshop efficiency curves—Core losses for various sized transformers—Specifications for transformers—Measurement of copper losses and drop—Iron testing. February 10.—Lecture IV.—The Employment of the Transformer: Defects in transformers—Causes of failures—Current rushes into transformers—Variation of core losses, with time and temperature—House transformers—Sub-station transformers—Two and three phase transformers—Transformer distribution—Importance of large power factor—Influence of load factor on annual losses—Capacity—Effects in case of large transformer systems—Designs for alternating-current stations—Conclusion.

"Superseding Electricity."—The latest claimant for journalistic electrical honours in America—the *Electrical Journal* of Chicago—has a formidable editorial staff, comprising, as it does, in addition to the managing editor (Mr. Hornsby), the following gentlemen: Henry S. Carhart, LL.D., Fellow Amer. Assoc. for the Advancement of Science, Foreign Member of the Institution of Electrical Engineers (London), Professor of Physics and Electrical Engineering, University of Michigan, etc.; William A. Anthony, Ph.B., M.A.I.E.E., Fellow of Amer. Assoc. for the Advancement of Science, etc.; Benjamin F. Thomas, Ph.D., Fellow Amer. Assoc. for the Advancement of Science, M.A.I.E.E., Professor of Physics, Ohio State University; William J. Herdman, Ph.B., M.D., ex-president of the American Electro-Therapeutic Association, Professor of Diseases of the Nervous System and Electro-Therapeutics, University of Michigan; Dugald C. Jackson, C.E., Member American Society of Mechanical Engineers, M.A.I.E.E., Professor of Electrical Engineering, University of Wisconsin. Yet, under the heading of this note, we find in a recent issue, without comment of any kind, the annexed paragraph anent what a humourist a long time ago termed "the Keely-Cranky motor": "It is said that John Jacob Astor has acquired the interest of Mrs. Bloomfield Moore in the Keely Motor Company, and will give it financial backing. Mr. Keely has promised the directors of his company that he will be through with his experiments by January 1 next, and that he will then put to a practical and successful test the results of his 20 years' labours. An expert who has investigated Mr. Keely's new force is reported to have said that 'There is no use in our devoting any more time to electricity. This is something far better. When Keely has constructed his railway traction engine, possessing rights over all the world, and using a costless force, and when a patent has been taken out on it the value of the discovery will be found to be incalculable. One of the directors of the company who recently talked with Keely is credited with the statement that the most wonderful use to be made of the new force is in the push-engine, or machine intended to propel street cars or vehicles of any kind on land or in the water. This is described as being a cylinder, 18in. by 8in. approximately, boxed up in portable form. This box is to be fastened to the front platform of the vehicle, and without any gearing or wire connection, or connection of any kind between the box and the wheels, the energy generated in the box is to turn the wheels and push the vehicle along. Some time next year it is expected that people will be able to get light, heat, and power for motor purposes in their homes and factories at trifling cost.'"

The French Method of Treatment for Electric Shock.—The prominent points of the circular which the Minister of Public Works in France has issued to the prefects throughout the republic on the measures to be taken in the event of an apparently fatal contact with live electric wires are the following: "The medical treatment of cases of shock is the same in all instances; but the steps to be taken for the preservation of the patient, or the safety of the helpers, are different according to whether the current

Digitized by Google

is a continuous or an alternating or commutated alternating one. According to the Academy of Medicine, the victim, even though apparently dead, must be at once taken, if no longer in contact with the electric wires, to a well-aired place, the number of persons in which is strictly limited to those whose services are necessary. The clothes are to be loosened (trousers and open shirt) and as promptly as possible you try to re-establish the respiration (as in the case of persons apparently drowned) by rhythmically pulling the tongue or by artificial respiration, and the circulation by rubbing the surface of the body, by whipping the trunk with the hands or with wet napkins, throwing cold water on the body from time to time, and by bringing ammonia or vinegar to the nose. The method for tongue-pulling is to open the mouth, using force by any convenient means, if necessary, as by the handle of a knife or a piece of wood; to grasp the tongue solidly, preferably with the aid of a pocket-handkerchief to prevent slipping; to pull the tongue forward, firmly and rhythmically, letting it slacken after each pull, about 20 times a minute; and keep this up for half-an-hour, an hour, or more. The method for artificial respiration is to lay the victim on his back, shoulders slightly raised, mouth open, tongue free; grasp the arms at the elbows, squeeze them firmly against the chest, then separate them, and bring them above the head, describing an arc of a circle, then bring them back to their former position at the sides of the chest. Repeat this about 20 times a minute, and keep it up until natural respiration is restored. It is better to begin in every case with the tongue-pulling, and, if possible, to carry on the artificial respiration at the same time. If the victim is still in contact with the wires the salvor must, before acting as directed, get him away from these. But in order to do that he must himself take certain precautions. For example, he must avoid touching him with the bare hands, and must wear thick gloves of dry stuff—linen or flannel of sufficient thickness; and he must not lay hold of the person injured by any wet or moist part of his body, as by his feet or under his arms. It may be necessary to cut the wires in order to free the body. But this is entirely inadmissible in the case of continuous currents, on account of the risk to the cutter occasioned by the spark or extra current on breaking circuit. It is not so with alternating or commutated alternating currents. In that case the wire may be cut without danger; but it is necessary to cut the wire on both sides of the victim in order to be sure that the cutting is really of use.

Behaviour of the Carbon Brush on Power Generators.—The *Electrical World* reproduces from the *Sibley Journal* for October a short article by Prof. Ryan, in which he gives an explanation of the action of the carbon brush on power generators. In dynamos for incandescent lighting the self-induction of the armature coils is small, the air gaps are large, and the E.M.F. of the field is easily maintained greater than the maximum of the armature; and under these circumstances it was easy to maintain suitable conditions for the successful commutation of the currents by means of metallic brushes; furthermore, the load fluctuates slowly. But when power generators came into use it was found that such a method of current commutation was utterly unsuited, and it was then that Vanderpole suggested the use of carbon brushes, which were found to be a great success; he thinks that a far greater part of the success of the electric street railway than people have thought has been due to the use of carbon brushes on the generators and motors: the load changes so suddenly that no adjustment is possible, and it is therefore of interest to see in what way the brushes take off the current, making their movement unnecessary, to avoid sparking. The self-induction E.M.F. formed by the sudden reversal of the current in such coils is high, and some sort of E.M.F. must be available to oppose this with a balance sufficient to reverse the current against the ohmic resistance; there is no aid of the E.M.F. generated in the fringe of the leading pole tips. Supposing that the brush completely covers one commutator bar and partially covers the two neighbouring ones, the restraint area of contact of one of the latter presents considerable resistance to the passage of the total current from one side of the armature, and this gives rise to a considerable local fall of potential, which diverts a considerable portion of the current through one of the two coils which are short-circuited, and as the entire surface of the bar connected to the other end of that coil is under the brushes, there is therefore less constant resistance. To explain the tendency to reverse the current he applies a similar argument; there is a restricted area of contact constantly diminishing with increasing resistance, so that just before a bar comes completely under the brush a high local fall of potential occurs, which causes some of the total armature voltage to divert the current by way of the neighbouring coil against the current already in that coil, causing it to reverse quickly in opposition to the E.M.F. of self-induction. In this way the high specific resistance of carbon is used advantageously for effecting commutation without the aid of the pole fringe E.M.F.; it cannot be depended upon for complete commutation, but in most generators with armatures of the iron-clad type fully half of the current may be thus commutated. In street railway generators it is usual to adjust the brush at no load, so that it is in the neighbourhood of the magnetic fringe of the leading pole tip, where the E.M.F.'s mechanically generated are sufficient to reverse one-half of the normal current. These E.M.F.'s are not sufficient to cause serious short-circuiting of the coils under commutation under no load and assist the carbon brushes. It is in this way that generators are now made sparkless under the most trying conditions.

The Comparative Cost of Gas and Electricity.—In the report which has been drawn up by Mr. A. P. Trotter, B.A., A.M.I.C.E., on behalf of the Hastings and St. Leonards Electric Light Company, a comparison is made as to the cost of lighting by gas and by electricity, the figures given being based on a series of photometric tests. The lamps used in the electrical tests consisted of three Edison-Swan 16-c.p. 100 volt lamps, which had been in use for some weeks previously; three "Gabriel" 16-c.p. 100 volt lamps, which were new; and one Edison-Swan "Sunlight" 100-c.p. 100-volt lamp. The comparison was made under fairer conditions than are usual in such tests, as good ordinary burners were used, in place of the Argand, so dear to the heart of the gas engineer when engaged in endeavouring to prove the superior economy of his product. These burners consisted of a "Christiania" burner tested with and without its opal globe, three steatite "Union" burners of the Bray type, two of which were marked No. 5 and the other No. 6, and one slit batswing burner. The results of the tests were as follow:

Lamps.	Volts.	Amperes.	Watts.	Total candles.	Candles.	Watts per candle.
E.S. 16	103	1·82	187·0	61·0	20·3	3·2
E.S. 100	102	2·46	251·0	—	103·0	2·43
Gabriel.	102	1·7	173·4	52·5	17·0	3·03

Burner.	Pressure.	Cubic feet per hour.	Total candle-power.	Candles.	C.P. pr. c. ft. pr. hr.
Christiania	34½	6·2	—	13·4	2·16
Ditto (with globe)	34½	6·2	—	7·9	1·27
Bray	24	34·0	39	13·0	1·15
Batswing	3	16·0	—	38·0	2·38

Mr. Trotter continues in his report: "It is perhaps some-

Digitized by Google

what beyond my province here to call your attention to the fact that the comparative cost of lighting by electric light and by gas must be considered on a wider basis than that of light for light. The saving in the cost of redecoration is very material, and the absence of injury to delicate goods in shops by the products of combustion and vapour of gas is of no little importance. Besides this, the wholesomeness of electric light for domestic lighting, though it cannot be set down in shillings and pence, is none the less valuable. Especially should this be considered in Hastings, where the very high pressure of the gas doubtless forces much unconsumed gas into the air. I assume that the price of electric supply varies from 4d. to 8d., and that incandescent lamps take a mean of three watts per candle, and that gas-burners yield two candles per cubic foot. The equivalent price of gas is :

Price per unit.	Price per 1,000 cubic feet.
4d.	2s. 4d.
6d.	3s. 4d.
8d.	4s. 4d.

Next, I assume that the price of electric supply is kept constant at 6d. per unit, and the efficiency of the lamps is altered. I desire to call your attention to the fact that the effect on the equivalent price of gas is no less marked, and that a knowledge of the efficiency of lamps, which can only be arrived at by careful photometric tests, is as important as a knowledge of the price of electric supply per unit. I have roughly estimated the alteration in life of incandescent lamps when run at a higher pressure, from the results of various life tests :

Mean watts per candle-power.	Renewals per 1,000 c.p.-hours.	Price of gas.
4	1d.	4s. 2d.
3	2d.	3s. 4d.
2½	4d.	3s. 2d."

Proceeding to consider the relative cost of arcs and Welsbachs, he says : "No strict comparison is possible, because the contract for arc lighting includes, I understand, the supply of carbons, trimming, cleaning, all repairs and maintenance of lamps and lanterns, and interest on capital outlay. I have no figures before me as to probable cost of lamp-lighting and cleaning, damage to mantles by gales and sea-water, general repairs and maintenance, nor have I any information as to the possibility of using incandescent gaslights in so exposed a position as that of your arc lamps. . . . . It may be assumed that for 1·11d. worth of gas the total may be put at 1·43d. for a naked light of 500 c.p. for one hour, exclusive of cost of lamplighters, cleaners, damage by wind and water, repairs, and interest on capital outlay. I understand that each arc lamp takes 15 apparent amperes at 50 apparent volts, or 600 true watts, and that for a service of 160,000 lamp-hours per annum, including supply of carbons, trimming, cleaning, repairs to 52 lamps and lanterns, and interest on capital outlay of lamps, post transformers, and mains, the sum of £1,300 is paid. This comes to 3¼d. per unit, or 1·95d. for a light, reduced and diffused by corrugated glass, of a mean of about 500 c.p. for one hour." In conclusion, Mr. Trotter observes that it is clear that the difference of 0·52d. would not cover the incidental expenses, and that, if the two systems of lighting were placed on equal conditions, the cost of gas lighting would largely exceed that of the contract for electric light. By the way, a dinner is to be given to Mr. Trotter at the Whitehall Club prior to his departure to take up his duties under the South African Government.

Direct v. Alternating Currents for Long-Distance Transmission.—Mr. Wm. Baxter, jun., discusses this subject in the New York *Electrical Engineer* of December 4. He says that there is a fascination about alternating-current problems that no doubt has had a great deal to do with making the system a favourite with the foremost electrical engineers. Most of these problems are so abstruse as to be beyond the comprehension of the average electrician ; therefore those who are gifted with a mind able to grasp the subject enjoy a certain amount of exclusiveness not obtainable in the simpler and more commonplace direct-current field. To determine the merits of the system for long-distance work, the best way is to analyse what has been done in that line. The most important work up to date has been the Niagara installation. According to the published descriptions of this plant, the main generators develop an E.M.F. of 2,250 volts. As this E.M.F. is too low for the increased transmission of current over any considerable distance, step-up transformers will be used to develop a current of higher E.M.F. to send over the line. At the receiving end a step-down transformer will induce a tertiary current of whatever E.M.F. the conditions may require. Inasmuch as, in the present state of the art, alternating currents can only be used successfully for incandescent lighting, and with partial success for arc lighting, it follows that for all other purposes a direct current derived from a rotary transformer will be required. Dealing with a direct-current system, in making the comparison Mr. Baxter assumes that the same E.M.F. is used. The method of transmission would be as follows : the generators would deliver a current of sufficiently high E.M.F. to pass direct to the line without any intervening transformation. At the point of distribution this current would operate rotary transformers that would generate a current of the E.M.F. required for distribution. It will at once be seen, the author remarks, that such a system would be more efficient than the alternating, because there would be only four sources of loss—namely, the generator, the line to point of distribution, the rotary transformer, and the local distributing mains. The average efficiency of the generators can be taken at 90 per cent., the same as that of the alternators. The line loss would be less with the same size conductors, but as the frequency in the alternating system here considered is only 25, the difference in the line efficiency would be less than ½ per cent. in favour of the direct current. He, therefore, takes the average line loss at 6 per cent., the same as for the alternating system. The rotary transformer could be made to give an efficiency of 85 per cent., but the present calculation will be based on 80 per cent. With these efficiencies the energy delivered to consumers would be about 64 per cent. of that applied to the generator shaft, against 54 per cent. for the alternating system. From the foregoing it will be seen that so far as efficiency is concerned the direct-current system is considerably ahead of the alternating ; but it may be contended that there are difficulties in the way that would make it, perhaps, impossible to obtain in practice the results above given. If, Mr. Baxter says, we could do away with the step-up and step-down transformers, the efficiency of the alternating system would be largely increased. Under such conditions it could more than hold its own with the direct current ; but whatever may be possible with respect to the step-up transformer, it certainly would not be prudent to drop the step-down transformer, and send the high-potential primary direct to the premises of consumers. Discarding the step-up transformer would not render the system as efficient as the direct, because the loss in the step-down and small transformers would be greater than that in the rotary transformer of the direct-current system. It is hardly worth the trouble, however, as the author remarks, to consider what the efficiency would be if the system of alternating-current transmission were different from what it is. We must consider the subject as it stands.

LECTURE XX.

(Specially Contributed.)

Mirrors and Reading Apparatus.—Prof. Chrystal says: "The glass of the mirror should be very thin, otherwise a greater or less correction for its thickness will be necessary. In the *subjective* method of reading, a scale is fixed before the mirror, which is usually plane (it must be well made to be of any use), and the image of the scale is observed by means of a telescope fixed over or under the scale,

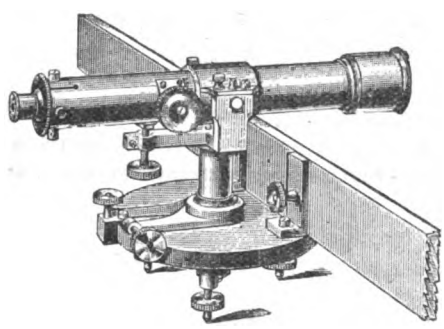

FIG. 1.

Fig. 1. The scale divisions are seen to pass the wires of the telescope, and if a circular scale be used whose centre is in the axis of suspension of the mirror, the difference between the numbers on the cross-wires in any two positions of the magnet is a measure of twice the deflection of the magnet. A correction is necessary when a straight scale is used. In the *objective* method, which is more usually used in this country, the mirror is concave, and reflects the image of a fixed illuminated slit (often furnished with a vertical wire where greater accuracy is required) upon a graduated scale. The readings are proportional to double the deflection of the needle, or to the tangent of the double deflection, according as the scale is circular or straight." The best form of scale probably to use is the transparent scale first introduced by Mr. F. Jacob.

Kelvin's Mirror Galvanometers.—Fig. 2 shows one form out of many in which this instrument is constructed. It is an astatic galvanometer. In it we have two systems

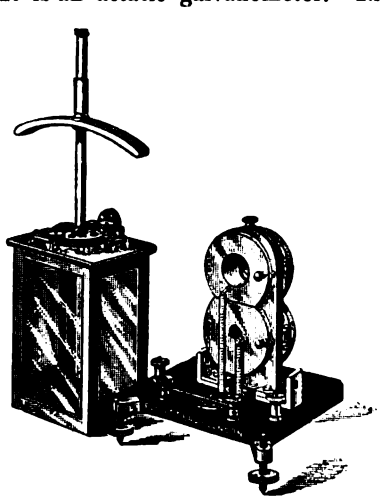

FIG. 2.

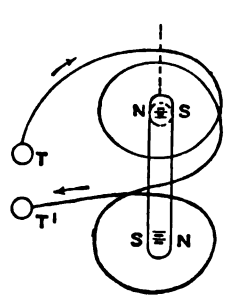

FIG. 3.

of magnets carried by a very light strip of mica, one system of magnets—the upper in this case—carrying also a very light concave mirror. In the diagram (Fig. 3) T T^1 represent the terminals of the coils. The direction of the current in the coils is shown by the arrows. The tendency of the current is to turn each needle in the same direction, as will at once be seen by referring to Ampère's rule. Each coil is really made up of two coils, which can be easily taken apart to allow of the putting in of the magnet system or of its examination. The magnet suspension is by means of a quartz fibre or of unspun silk, and is such that the system can be slightly raised or lowered without putting any torsion on the suspension. The coils are surrounded by a glass case carrying a controlling magnet. This controlling magnet allows the sensitiveness of the instrument to be increased or decreased within certain limits. First, however, if the astatic system be imperfect, the controlling magnet can be so placed that it keeps the spot of light at zero when no current is passing. If it is desirable to have the system controlled by a weak magnetic field, the controlling magnet—which is, of course, a permanent magnet—is raised on the vertical rod as high as it will go. If we want a stronger field, we lower the permanent magnet on the rod. These instruments are usually placed upon an ebonite base to secure good insulation, carried by three levelling screws, and the apparatus must be carefully levelled before use. Duplicate sets of coils are frequently supplied with these instruments. Thus one set of coils may have as small a resistance as half an ohm, and the instrument can be used with large currents, while another set may have a resistance of 10,000 ohms, to be used with small currents. Instruments of this kind have been made with coils of over 350,000 ohms resistance.

Shunts.—Frequently we have to deal with currents that would injure these delicate galvanometers, and to guard against such injury, and to increase the range of the instrument, we add another path for the current parallel to the galvanometer, and this we call a shunt.

There is only one way to reduce the current through a galvanometer, and that is by the reduction of the acting pressure across its terminals. The shunting of a galvanometer thus always means the reduction of the pressure acting across its terminals.

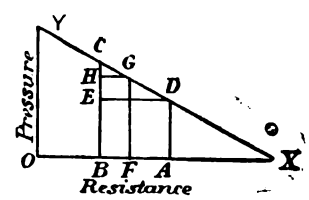

FIG. 4.

In Fig. 4 let O Y represent total pressure of circuit;
let O X represent total resistance of circuit;
let A B represent resistance between terminals of galvanometer.

From A and B draw A D, B C parallel to O Y.

From D draw D E parallel to O X.

Then E C will represent that part of the total pressure which is used in overcoming the resistance A B.

If, now, the galvanometer is shunted, the resistance between its terminals is lessened—it is, in fact, the joint resistance of shunt and galvanometer.

Let this resistance be represented by B F.

Through F draw F G parallel to O Y.

Through G draw G H parallel to O X.

Then H C will represent the pressure used to overcome the resistance of the shunted galvanometer, and the current through galvanometer will be that due of pressure represented by H C.

The insertion of the shunt has also decreased the resistance, O X, but to keep the resistance, O X, constant, and hence the current of the circuit constant, a resistance = F A is inserted as a compensating resistance.

Usually three shunts are made for every galvanometer, so that in one case $\frac{1}{10}$th of the current goes through the galvanometer and $\frac{9}{10}$ths through the shunt. In the second case the currents are respectively $\frac{1}{100}$th and $\frac{99}{100}$ths, and in the third case $\frac{1}{1000}$ths and $\frac{999}{1000}$ths.

Let us consider that in any circuit the current is found by the use of the formula,

$$C = \frac{E}{R}.$$

Now, if we decrease R to R_1, with E constant, we increase current from C to C_1.

By the introduction of a shunt across the terminals of the galvanometer we do decrease the total resistance of the circuit, and E remaining constant the current is increased. As a rule we do not want to measure the new current,

Digitized by Google

but the old, and to do this we must restore the original resistance of the circuit.

Thus, roughly speaking, if we shunt a galvanometer we alter the conditions, which we more or less restore by the adding of a compensating resistance to the circuit.

Assume this all done and that the current in the new circuit is the same as the current in the old.

Now, the number of amperes per second passing through any one section of the circuit is the same as for any other section of the circuit. Let Fig. 5 represent the circuit

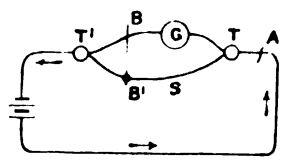

FIG. 5.

with galvanometer and shunt. Imagine sections of conductors at A and B. The current passing through section A will pass through any section, as at B B_1. No more and no fewer amperes will pass B B_1 per second than pass A. In fact, we may look upon the two sections B B_1 as forming one section of a thicker wire, and all that would take place in a circuit wherein the conductor varied in area would be that the density of current flow at the smallest section would be greater than at the larger section.

Let C = current.

C at T divides between T G T_1 and T S T_1 inversely as their resistances.

If the resistance T G T_1 is nine times that of T S T_1, then one part of C will go by T G T_1 and nine parts by T S T_1.

We can arrange the shunt resistance so that any portion we desire of the current shall go by it.

Thus if $\frac{1}{10}$th of current is to go through galvanometer, we must have a shunt that is $\frac{1}{9}$th of the resistance of the galvanometer.

To find the resistance of a shunt so that n times the current going through the galvanometer goes through the shunt, we simply divide G, the resistance of the galvanometer, by n; thus $\frac{G}{n} = S$, the resistance of the shunt.

A galvanometer has a resistance of 9,000 ohms. What is the resistance of a shunt that takes $\frac{9}{10}$ths of the current?

Here the shunt current is nine times greater than the galvanometer current, so the resistance of the shunt must be $\frac{1}{9}$th that of the galvanometer—

$$\frac{9000}{9} = 1{,}000;$$

that is, the shunt will have 1,000 ohms resistance. If nine parts of the current go through the shunt and one part through the galvanometer, then the total current is 9 + 1, or 10. Thus, if $\frac{1}{n}$th part of the current is to go through the galvanometer, the resistance of the shunt $\frac{1}{n-1}$th part the resistance of the galvanometer.

Suppose we want to find the total current—that is, the current flow through any other unshunted section of circuit. We use a multiplier, called the multiplying power of the shunt, and this is merely the sum of the ratios of the resistance of the galvanometer and shunt. In the above case the ratios are

9 : 1 and 9 + 1 = 10, which is the multiplier wanted.

We know the current, C, going through the galvanometer, then $10 \times C$ = total current.

If the ratios were 6 : 1 then 6 + 1 = 7 would be the multiplier.

" " 99 : 1 " 99 + 1 = 100 " " "

or,
$$\frac{\text{R of galvanometer} + \text{R of shunt}}{\text{R of shunt}} = \text{multiplying power of shunt.}$$

Differential Galvanometer.—This is a galvanometer in which the needle is acted upon by two equal coils wound so as to oppose each other. When equal currents go through the coils the needle remains at zero.

Ampere-Meters.—For short, these instruments are generally called ammeters. The delicate instruments hitherto mentioned are not suited for measuring large currents. The ordinary current used in an electric light station would most probably fuse the wire of the coils and destroy the instrument. Hence, with the introduction of the use of larger currents, different instruments were devised. M. Deprez was perhaps the first to devise such an instrument, modifications of which are now to be found in every light and power station.

The principles upon which these instruments are based are very simple. In the first place, it is very desirable to do away with all arithmetical calculations, and to make an instrument which shall read directly in amperes. The divisions of the scale of the instrument used then indicate amperes, and if the pointer point to the division marked "20," or to that marked "30" or "300," we read 20, 30, or 300 amperes, as the case may be, without troublesome calculations about tangents.

An instrument of this kind is simply constructed. Let N S (Fig. 6) represent a strong permanent magnet. If, now, a

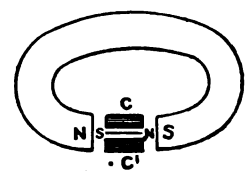

FIG. 6.

small needle, n s, be suspended between the poles, N S, its position at rest may be said to be controlled by the magnet, and the position of the small magnet or the light pointer carried by it may be marked on a scale as the zero position. Let the coils, C C_1, have the current to be measured passed through them. The effect of the current field will be to deflect s n from its zero point. If, now, we make a scale showing by means of a pointer the zero position—that is, the position of s n when no current goes through the coil—and the position when one, two, three, four, etc., amperes go through the coil, we shall have an instrument whose readings show amperes. The current going through the coils may be measured by means of a standard instrument. Various ways have been used to hold the needle in the zero position. As we have seen, it can be done by the aid of a permanent magnet; it can also be done with the aid of an electro-magnet, by means of a spring or by the action of gravity. Thus we get permanent-magnet, electro magnet, spring, and gravity ammeters.

Permanent magnets have the great defect that their magnetism may be temporarily or permanently altered by being brought into strong magnetic fields, such as are found among dynamos. Time also affects permanent magnets, and any of these changes affects the value of the scale readings of the instrument. Hence, if such instruments are used, they should be frequently calibrated or tested to ascertain the continued correctness of the scale reading. It usually suffices for the makers to obtain the scale of the instrument by using a standard ammeter; but if extreme accuracy is desired, or if there is no standard at hand, the electrolytic method must be used. Here is a form of ammeter that has been largely used. A short needle, n s, is fixed on a shaft, P, Fig. 7 (the shaft turns on jewelled

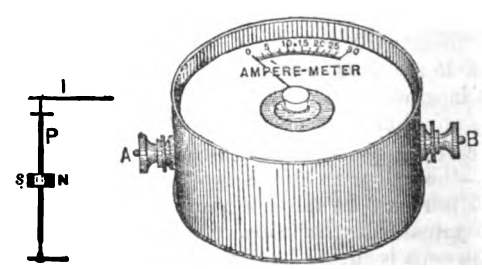

FIG. 7.

pivots), and mounted between the poles of two strong magnets, as shown in plan (Fig. 8). The current to be measured goes through the coils, C C, wound with wire suitable to carry the currents to be measured, for, as Prof. Ayrton puts it, *the test must not alter the thing tested.* If the current

Digitized by Google

increases from zero, the needle moves through an angle increasing with the current, and the pointer moving with the needle, points to the value of the current on the side. It may be well to explain a little more fully how to make this scale in the absence of a standard ammeter.

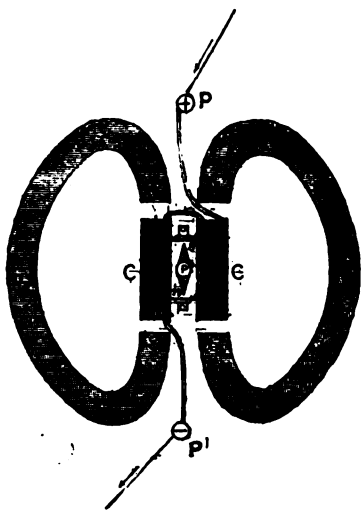

FIG. 8.

Take any scale of equal divisions and put it under the pointer. The zero may be marked when no current goes through the coils. Take an electrolytic cell, say, depositing copper. Carefully weigh the electrodes, which should be movable, for to obtain an accurate scale point the current through the circuit must be kept constant. Connect up ammeter with cell in the circuit, and note deflection of pointer. While the current through the circuit is constant this deflection is constant, and if the cell should become weak and the current drop, the electrodes can be brought a little nearer so as to decrease the internal resistance of the cell, and thus keep constant current. Keep the experiment going, say, 30 minutes, and then find amount of copper deposited, say, 2·958 grammes, or at rate of 5·916 grammes per hour. Now, *one ampere* current deposits 1·183 grammes per hour, so the current used is $\frac{5{\cdot}916}{1{\cdot}183} = 5$, or five amperes. Thus we can mark the point on the scale where the pointer stood during the experiment 5, and in like manner can obtain other points.

Profs. Ayrton and Perry introduced a modification of the Deprez ammeter into England, and have since designed instruments not controlled by permanent magnets. Fig. 9

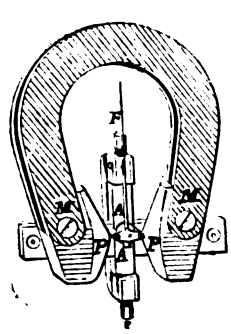

FIG. 9.

shows the form with permanent magnet. The needle is placed in a brass tube between the soft-iron pole-pieces, P P, of the magnet, M M. The spindle carrying the needle also carries an aluminium pointer. The coil through which passes the current to be measured is wound on the brass tube, A A, at the ends of which are soft-iron screws, F F, to assist in adjusting the instrument.

Spring Ammeters.—The introduction of these instruments is also due to Profs. Ayrton and Perry. Here the controlling force is a spring. The important feature of this instrument in the special form of spring employed. The peculiarity of this form of spring, in the words of Prof. Ayrton, is that for a small increase in length along the axis there is large rotation of one end of the spring relatively to the other, the angle of rotation being directly proportional to the axial extension. If, then, one end of the spring is fixed, and the spring be slightly pulled axially towards the other end, a pointer fastened to the movable end will move through a comparatively large angle. This motion of the pointer can be read on a scale.

The spring, S, made of phosphor bronze, is fastened at the bottom of a thin tube of soft iron, B, by the brass cap, D. The cap has a square shank, which fits into a square guide-piece, so that it cannot turn. The spring, C, is suspended by a thin wire, W, carrying a light aluminium pointer, P.

If now, the soft-iron core, B, is put partly into a solenoid,

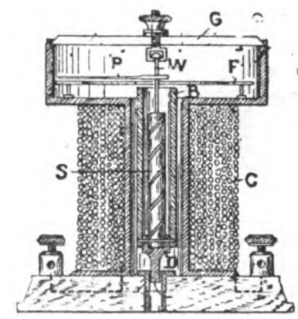

FIG. 10.

a current sent through the coils of the solenoid pulls the soft-iron core, so that a pull axially is exerted upon the spring, C. The lower end of the spring cannot move, but the upper end can rotate, and under the influence of the axial pull does rotate, carrying round the pointer, P, which in the instrument is swinging over a direct reading scale. A section of the complete instrument is shown in Fig. 10, where A C shows the coils of the solenoid, G, the glass top of the instrument, F the scale.

Edison's Ammeter.—In Ayrton and Perry's instrument a soft-iron core is sucked into the solenoid. So, also, in Edison's, but the latter has no spring (Fig. 11). In it we

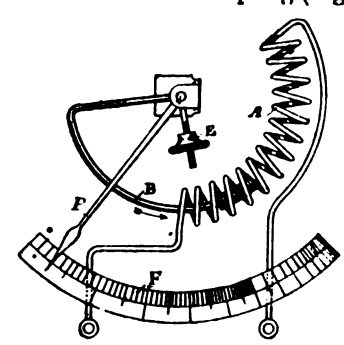

FIG. 11.

have a solenoid, A, with a bent core, B, of soft iron. The core, B, has a counter-weight, E, so fixed, and of such a weight, that the pointer, P, is at zero when there is no current in A.

Weston Ammeter.—A form of instrument largely used in America and becoming a favourite in England is shown in Figs. 12 and 13. Here the coil, C, is placed between the

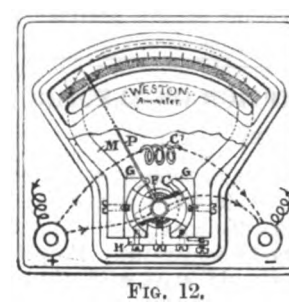

FIG. 12.

poles of the permanent magnet, M. A shunt-coil, C, is placed in parallel with the coil, C. The latter is wound upon an aluminum frame, delicately pivoted, and carrying a pointer, P. A soft-iron cylinder, F, concentric to the pole-pieces, G G, is supported by the brass crossplate, H, which extends across the pole-pieces. The movable coil,

Digitized by Google

C, is held in the zero position by two flat horizontal springs, S S, fastened to the ends of the coil one above and one below. The cross-section of the permanent magnet is in the standard instruments 1·25in. × ·3in. I have said

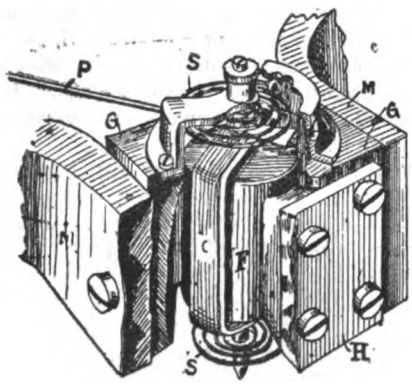

FIG. 13.

that one objection to permanent magnets is their liability to change. After a time, however, this liability to change is small, and the intensity becomes fairly constant. Such a magnet has been called "aged." In the Weston instruments the permanent magnets are carefully artificially "aged." The gap between the pole-pieces and the iron cylinder is ·04in. ; the radial thickness of the coil, including the aluminum frame, is ·015in., leaving a clearance at each side of the coil of ·0125in.

Uppenborn and Schuckert Ammeters.—A very interesting form of ammeter is this, and the construction is simple. Fig. 14 shows the whole principle. The coil, C,

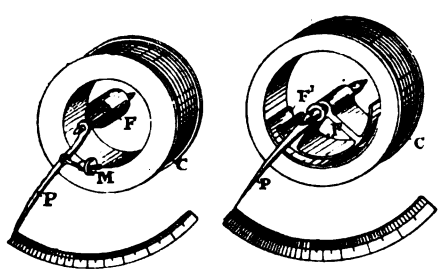

FIG. 14.

carries the current. In the Uppenborn instrument, F and F^1 are two soft-iron cores—F^1 fixed and F pivoted and movable. When a current passes through C, these soft-iron cores are similarly magnetised, and a repellent action takes place between them. The core F^1 is set slightly forward in the direction it is wanted to move. It carries a pointer, which points to zero on the scale when no current is passing. In the Schuckert instrument only one soft-iron core, F, is used, and this is placed eccentrically in the interior of the coil on an axis parallel with the axis of the coil. The core carries a pointer, and is adjusted with the aid of a counterweight, M, so that the pointer is at the zero of the scale when no current passes through the coil. When a current passes, the core gets nearer and nearer to the coil till it touches, when the pointer stands at the extreme position of the scale.

POWER CONSUMPTION ON ELECTRIC RAILWAYS.*

BY A. K. BAYLOR.

The subject of power consumption on electric railways seems to naturally divide itself into two parts: first, the apparatus itself, its efficiency and general construction; second, the handling of apparatus. Properly, a consideration of this subject should start with the coal pile, but it is proposed here to consider it merely in its relation to the electrical apparatus, taking the power as it comes from the engine shaft. One of the first questions bearing on the efficiency of the generating plant that must be considered is whether direct-connected or belt-driven generators are to be used. In a paper recently read before the Pennsylvania Street Railway Association, the writer pointed out that the experience of the last two or three years has shown direct connection to have, in most cases, everything in its favour, and that where land values are high and the units large, these two points alone will dictate the choice of the type of machine. It was at first supposed that the great fluctuation of load inevitable in railway work would introduce a serious menace to the unit—*i.e.*, the engine and generator—when the two were rigidly connected; but this has been shown by repeated experience to be a negligible factor when a properly proportioned flywheel is introduced between engine and armature.

In comparing the two types of machines, the first consideration is apt to be the relative cost. As a direct-coupled generator is usually designed to give a certain output while running at slower speed than a belted generator for equivalent output, it must be large and cost more than the belted machine. From the difference in cost, however, must be deducted the expense of belts, and several other money-saving features must be considered. The direct-connected machine takes less room, saving land and permitting the use of a smaller building. Only one foundation is necessary, instead of two, and although the one foundation must be larger than either of the two necessary for a belted unit of equal power, it will usually cost less than the sum of the two. Furthermore, there are fewer bearings and wearing parts to care for, and last, but not least, a saving in efficiency of from 5 to 6 per cent. according to the proportion of load on the generator. This difference in percentage is due to the fact that the least possible friction loss due to belting is in the vicinity of 4 or 5 per cent., and even if this minimum be preserved at full load it becomes about 8 or 10 per cent. when the generator is running at half load. These considerations will usually effect a decision in favour of direct coupling, unless they are offset by a saving in interest charges due to an unusually low-priced belted generator.

The next point to be considered seems to be the proper division of the plant into units. Generally speaking, perhaps the best investment is made by the installation of three units of equal size, two of which are capable of carrying the full load. This permits efficient running at half load and full load, and leaves one unit always in reserve. It is, of course, desirable for the sake of efficiency and consequent economy of power to run all the working machines as near full load as possible, and to keep "on top" of the efficiency curve, and, with this object in view, some roads have made a division of power into, say, two large units, each equal to one-half the full load, and one small one equal to one-quarter load. This permits full-load running practically all the time, as combinations of these machines will give one-quarter load, one-half, three-quarter, and full load; but in case one of the large units gives out, the remaining one-half and one-quarter unit will have to be considerably overloaded to handle the full load of the station.

It is interesting to note how daily records of current output by readings taken every few minutes will show the separation of the day into distinct load periods which will repeat themselves with astonishing accuracy from day to day when the same general conditions obtain. For this reason, and because it is impossible to keep playing the generator units into combinations to fit all these fluctuations, it is necessary to choose a generator at the outset with a good efficiency curve; in other words, a "flat" curve, one which rises to 90 per cent. or thereabouts, at a comparatively small load, and gradually rises with the load to a high maximum, running then on a practically horizontal line, until the load becomes excessive. As contributing to this result, the machines should run without excessive heating, which means ample capacity in conductors, commutators, and armature, large radiating surfaces, good ventilation, and sufficient bearings. They must run free from sparking up to reasonable overloads, and must have insulation of sufficient resistance to prevent leakages to ground, and after all this they must be kept clean.

Buyers should also remember that the manufacturing companies whose engineers have made these points a matter of special study, and have the experience of scores of plants to guide them, ought to be, and are, in a position

* From *Cassier's Magazine.*

Digitized by Google

to judge intelligently of the general proportions best calculated to give a certain result. The buyers should therefore confine their specifications, in a reasonable degree, to a list of conditions to be fulfilled, naming the heating, sparking, and overload limits required, with other general features, leaving the means for reaching these ends—*i.e.*, the size of conductors, number of commutator bars, thickness of insulation, and the thousand and one details of design which go to make up an efficient machine—to the makers. A great deal would be gained in this direction if consulting engineers fully realised that unless they have given the matter enough study to qualify them as generator designers, they may, through insisting on some peculiarity of detail and receiving a generator fulfilling their specifications, get a machine inferior to what would have been furnished had the manufacturer been held accountable for results only.

As bearing on the general efficiency of the system, the line should be of ample capacity and of insulation sufficient to withstand the potential at all times. The ground return capacity should, of course, be equal to the overhead feeder. An abundance of overhead copper with bad rail bonding, with, perhaps, open circuits, is an absurdity. As affecting the life of the motors, the feeders should be distributed to deliver as nearly as possible an even potential all over the line, and while the voltage should not be allowed to drop too low, it also should not be raised to any considerable degree above the normal point, as this puts the motor insulation under undue stress. On this account, when cars run directly past the power-house, the feeders should not attach directly to the line, but should spread in either direction and feed back to this point. It is evident that when a motor has become dusty or moistened in service, its insulation resistance is reduced, and any excess in potential above its safe limit will result in punctures of the winding and other leakages to ground; whereas, if the pressure be kept inside this limit, if only by a few volts, the bulk of such trouble may be avoided.

Of course, the motor is another factor of prime importance in the economy of power, and what has been said under generators regarding efficiency will apply in a general way here. A motor should be as light as is consistent with strength and power, and should be compact and protected by its frame. The most important consideration in the purchase of motors may be safely said to be cost of maintenance, but this has no direct bearing on the economy of power, much as it has to do with economy of operation. As a power saver, the most important part of the car equipment is the controller. The time has gone by when it was necessary to draw comparisons between rheostatic and series-parallel control in considering equipments; yet a good many lines are operating rheostatic controllers without apparently appreciating the loss they are sustaining. Aside from the out-and-out saving in power by the use of series-parallel control, which amounts to a clean 25 to 40 per cent., according to the series, it should be remembered that the necessary generating plant for operating with such controllers is much less than that required for the same car service under rheostatic control, not only because of the average economy of power, but because the momentary fluctuations of load, which must be taken care of, are much less violent, and this latter condition holds good in any case, even for a high-speed road making few stops, and where the motors are kept in multiple so much of the time that the average power consumed is practically the same for both methods of control.

Another practical advantage is found in the possibility of running all the cars at half speed in case of the disabling of half the power-house capacity. This is an important consideration, for instance, on a stormy day, perhaps during a snowstorm, when the first desire of patrons is to get aboard cars in large numbers, away from the weather and to be carried to their destination. At such a time the number of minutes consumed in getting there is usually a secondary consideration. Tracing up the subject of operation at the power-house, one of the most effective economies is the use of recording wattmeters registering the load continuously. By this means, and in connection with readings on individual cars, load curves may be established, representing fairly (by the division of the day into load periods, as mentioned above, and the current output during those periods) the power which should be consumed to handle a given traffic. In this way a careful and intelligent comparison may be drawn between different days in a season and between days of similar character. Wattmeter readings on separate cars are of especial importance, establishing, as they do, for the unit what the station readings show for the whole system. Repetitions under all conditions will show whether a certain car should consume 800 or 900 or some other number of watt-hours in running a mile, and any sudden or wide variation to-morrow from the standard load readings of to-day and yesterday will indicate a leakage of some sort and attract prompt attention. Without such a system of checks in the delivery of current, there is nothing but the sluggish coal pile to betray any irregularity in power consumption. In addition to these guards, a recording voltmeter should be used at the station, or a voltage record kept at very frequent intervals. With due allowance for over-compounding, the theoretical record would be a circle, and in practice, with a fairly constant load, the record should approach this standard. If the voltage undergo wide fluctuations, comparing different times of the day, the generator is faulty, or the station man is negligent, and in either case the motors suffer, and they not only require a greater average current to do a given work at reduced voltage, but they will consume more watts in doing it.

A very great factor in saving power is the degree of intelligence of the motormen. They are too often put upon cars with scarcely any preparation and are then practically left to their own devices, and naturally handle their cars uneconomically. They will often move the controller handle around the dial without regard to the notches, passing into No. 2 before acceleration of the first position has been felt, and so on to Nos. 3 and 4. It sometimes practically amounts to throwing the handle immediately into the first position. As far as economy of power is concerned, such men might almost as well have rheostatic controllers. The pity of it is, too, that as a rule the men are not to blame, never having received proper instructions. A valuable aid in the education of motormen is the use of an ammeter in the motor circuit, in plain sight, so that during their run the men can see the fluctuations of the instrument and note the results of incorrect handling as compared with the right method. The plan followed by Mr. Know, of the Chicago City Railway, is certainly an excellent one. He has printed curves, laid upon one plot, comparing the current fluctuations with right and wrong methods of starting, posted around the car barns and employés' rooms as a graphic object-lesson which has resulted in an economy of power. Further than this, motormen should be instructed in the car circuits, with diagrams showing the connections at each position of the controller. With this knowledge a conscientious man would involuntarily make an effort in the right direction.

Another great coal consumer is the brake. A great amount of power is wasted by men who throw their controllers into contact before thoroughly releasing brakes, even when there is no danger of backing. They also throw on the brake before throwing off the power. Very few men understand or attempt to use the momentum of their car to advantage. They will run with power on close up to a leading car and then apply brakes, when they might coast many feet, using no current whatever. This momentum may also be used to advantage on curves, switches, or wherever there is unusual resistance. The careful scheduling of cars with respect to grades may be an important economy, and although it is a complicated problem, it is worthy of more attention than it is usually given. Care should be taken to keep bearings and running gear in good condition and to maintain track gauges. The wheels upon any truck should be made of the same diameter (a precaution frequently overlooked) to permit the motors to wear in perfect unison.

A full consideration of this heading leads into every branch of the operation of electric railways, and although the efficiencies of apparatus and the direct handling of it are the first things to consider, every fault in system or operation is directly or indirectly an attack on the coal pile.

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscriber can have their own copies bound for 2s. 6d., or covers or bindin can be obtained, price 2s.

A MERRY CHRISTMAS.

It is almost impossible at Christmas time to write on technical subjects when we know that the words written will in many instances reach readers during the week when only that which is glorious in mundane affairs should be recognised. The most violent partisan, the harshest critic, could not write anything obnoxious at a time which breathes naught but peace and goodwill. There is no technical subject about which we are all agreed, but there are many about which our differences are merely on matters of detail. The goal aimed at is the same; the paths to arrive at that goal are different. To-day, then, let us refer to a subject about which there can be little divergence of opinion—the subject of education. Everyone admits that education is necessary for success in life, but we are not agreed upon the kind of education necessary to fit a man for technical work; and ofttimes wordy warfare takes place between speakers and writers, all of whom are desirous of doing good, but each is speaking or writing of a different thing. Is it not singular that the agitation for technical education is as keen now as it was three-quarters of a century ago, or perhaps it would be better put the other way about—and was as keen then as now? If men knew what they really wanted, would this talkee-talkee go on for so many years without tangible result? Do we really admit that, in the first place, education, in the second place, technical education, is so all important? There is no doubt about such admission. How, then, can we account for the bitter cry still going on for technical education, except on the one hypothesis that no one as yet has satisfactorily defined what is really wanted? Seventy years ago we read of Henry Bell—the real designer of the steamboat—that "he also constructed a steam-carriage to ply upon a common road, but, as the high-pressure engine was indispensable, and as it was suppressed by Act of Parliament, his invention was abandoned." This week we read of an innovator being fined for running a motor-carriage on the highway. What can be said of educational progress in this particular direction? Brougham, at the first annual dinner of the London Mechanics' Institution on December 2, 1824, said, "He could not help thinking that those who should live forty or fifty years hence would witness such a change in the condition of mankind, from the existence of these institutions, as would be really astonishing; and he doubted not that those who were present would, if spared only ten or five years, see great improvement, if the same spirit continued, in the condition of mankind, arising from the diffusion of knowledge; and they would recollect that knowledge was power." Now, we who live later know that the energy which founded "Mechanics' Institutions" expended itself, was revivified in the forties, gathered vigour in 1851, and has continued to expand ever since. Is not much of the energy wasted because of the indefiniteness of the aim? The same publication that tells us of Brougham and Birkbeck quotes a note from Adam Smith to the effect that that little article, a pin, passes through eighteen different hands in the course of its manufacture. The question may well

Digitized by Google

be asked when visiting a machine shop, What is the particular technical education that will make this or that man more effective in the performance of his duties? In the vast majority of cases a man pursues one class of work all his life. From the industrial and economic point of view, then, is it not a waste of energy to ignore his particular work and teach him something else? Are we not trying to fit everybody to become masters, and designers, rather than workers? Do we not neglect almost all the technical education that will assist to make home life happy and the workman's labour more efficient in order to give him notions which he can never use? In doing this, do we not teach a smattering of everything and get thoroughness in nothing? But Christmas is with us, and we only ask these things to know if our aims are really direct, and if not, cannot they be made more direct?

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION.

SIR,—Some years ago I found myself in identically the same position as Mr. Raworth was at the last annual meeting, and although the proposals I wished to make were, I think, calculated to enhance the usefulness of the Institution, I refrained from getting 10 members to ask for an extraordinary meeting. Put it as we will, an extraordinary meeting convened at the request of members has an appearance of hostility to the Council, which none of us want. I venture, however, to express the hope that the Council will themselves appoint a committee for the purpose of considering whether a revision of the rules has not, by reason of the vast increase of members, become desirable. If the committee arrive at the conclusion that the rules may be improved upon, the proposed revision could be circulated amongst the members, and the Council themselves might call an extraordinary meeting.

Having said so much, perhaps one ought to suggest one or two alterations that seem worth consideration. Do we not use up our presidents too quickly? Why should they not keep office for two years? As to qualification, the second rule is, to say the least, vague. Is it not an anomaly that the senior vice-president should be entitled, in the absence of the president, to preside at a Council meeting, and yet may by some not be considered eligible for the office of president?

And last, though not least, surely in a large Institution such as ours has become there ought to be some legitimate and recognised method by which members may at the annual meeting bring forward proposals for the benefit of the Institution without being placed in the invidious position of being obliged to move an amendment on the report of the Council.—Yours, etc., S. FLOOD PAGE.

THE ARC LIGHT.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

LECTURE I.

(Continued from page 660.)

We have in general the same sort of sloping things as previous experimenters have found. But the lines that correspond to different pressures all slope down from right to left. They are not all straight, though straight over a considerable range. The "one atmosphere" line is not quite straight, for it begins to turn down when the length is small. But its straight part points toward 40 or 39 according to the current that is being employed. Now, if my theory is true, that the arc temperature is that at which carbon is vaporised, it follows that if you put on the pressure you ought to have exactly the same sort of effect as happens in boiling liquid when you put on pressure: you raise the temperature of boiling. In the present case you raise the temperature of evaporation, and require more energy to make it boil—that is to say, it will boil, other things being equal, with a bigger back E.M.F. The diagram shows the line for two atmospheres, for four, for six, and for ten. Let us pass at once to the last as being the extreme case. The "ten atmospheres" curve points back to 48 volts instead of 39, proving, in fact, that more work is done by the current in going through the arc when it is made more difficult for the carbon to evaporate from the crater into the arc itself. There are some other things which might be noticed in this figure. For instance, when working in a vacuum, short arcs require less E.M.F., and long arcs a greater than is required in air at the ordinary pressure. The next diagram, Fig. 8, is also one of Duncan's, plotted out in a different way. Here he is employing a constant length of arc, but varying the pressure. As you increase the pressure from vacuum first to one atmosphere, then to two atmospheres, and so on, you notice what happens. With a very short arc there is a continuous increase in the volts required, but if the arc is $\frac{1}{8}$in. long, and you pass from vacuum to one atmosphere, you want fewer volts. It is easier to send an arc through air than through vacuum when it is only $\frac{1}{8}$in. long, but after that the electric pressure required increases. Suppose you begin with a $\frac{1}{2}$in. arc, there is a very distinct lowering of the voltage, but a little over 5 per cent. in amount. Yet, on raising the pressure above one atmosphere, the voltage again increases. All this points to something not yet discovered.

Now, let us try to sum up what is known on this point. Carbon, the most refractory of known substances, has a definite temperature of volatilisation when the pressure is kept constant. Change of pressure will change that temperature. However intense the heating effect of the current, however fiercely we pour in energy by means of the electric circuit, we cannot raise the free surface where the carbon is evaporating above that limiting temperature. Increasing the rate at which heat is poured in will simply increase the rate of evaporation. Further, carbon is found at these elevated temperatures to have chemical properties of the most active kind. No known compound exists that is not dissociated at arc temperatures. Put any of the most refractory substances known—lime, magnesia, alumina, asbestos—into the arc, they are dissipated, reduced, volatilised; mix any of them with the carbon, and one finds that, without exception, the effect of their presence is to reduce the temperature, to lower the degree of luminosity, and—what is most significant—to lower the apparent back E.M.F. Increase of pressure, however, raises the temperature and raises the luminosity. What a glimpse this gives us of the possible state of things going on at the surface of the sun. For some reason—into which I need not enter—the temperature at the sun's surface is very high, higher, to judge by the radiation, than that of the crater of the arc. Also, the pressure of the solar atmosphere, at the level of the sun's surface, must be much higher than the one atmosphere of our air. At such temperatures (and pressures) all known chemical compounds would be dissociated into their elements, and all the known elements would be volatilised. The last element to be volatilised would be carbon. Are we not justified, then, in hazarding the suggestion that the luminous surface of the sun, to which it owes its brightness, is in reality a surface of incandescent carbon? If not, what else can it be?

Remarks since added, October, 1895.—It is only just to add, in view of later researches, that there is some evidence not concordant with the views put forth in this lecture in January. Experiments made in Ireland by Mr. W. E. Wilson go to show that under certain conditions the light given out by an arc lamp is reduced in brilliancy when the lamp is burned under a pressure of several atmospheres. Mr. Wilson considers that he has shown that the intrinsic luminosity is lowered. If this should be established it will, of course, mean that the temperature also is lowered by pressure, and that therefore the temperature of the arc cannot be considered as dependent upon the temperature of volatilisation of carbon. But it remains to be proved whether the temperature of volatilisation of carbon is so lowered by pressure. The matter is complicated by the circumstance alluded to in the lecture, that the melting point of carbon is so close to its boiling point. In the absence of any knowledge as to whether at the fusion point any change of volume occurs, and whether such change be an expansion or a contraction, it is impossible to say whether increase of temperature will raise or lower the melting point. All one can say is that the question raised is still in suspense, and that for the present Mr. Wilson's observations are distinctly against the theory put forward.

Further, in September, 1895, at the meeting of the British Association, Prof. Ayrton and Mr. Mather communicated a paper on the apparent back E.M.F. of the arc, which they had been examining by a new method of electrical measurement. This method cannot be discussed here, but there are grave doubts as to its validity. Using this method, the extraordinary result was obtained that the supposed back E.M.F. is a negative

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

quantity—that is to say, instead of an E.M.F. opposing the current, they found a forward E.M F. helping it. If this were true, it would involve the admission that the arc would be acting as a source of electric power, and it would also involve the admission that the resistance of the column of vapour of the arc is greater than can be accounted for by the fall of potential per unit of length, both of which conclusions would be inadmissible.—S.P.T.

Researches of Prof. Ayrton.

Any account of the physics of the arc would be incomplete which did not include a reference to the researches of Prof. Ayrton. I listened, when at the Electrical Congress at Chicago in 1893, with the utmost delight to a very elaborate paper which cleared up a number of doubtful points, and gave us far more complete details about the phenomena of the arc than anything hitherto available. The same sort of observations had been made by Prof. Ayrton and by Mrs. Ayrton as those which I and other observers had made in time past. They had been carefully comparing the length of the arc, the voltage, the current, size of crater, and so forth, but over very much larger ranges and with more perfect appliances than any previous observer. In particular, they had found that if after adjusting any of the conditions as to length, current, and the like, a sufficiently long time (exceeding half-an-hour, if I remember aright) were allowed to elapse, the crater and peak settled down to a special form corresponding to those conditions. And that to every change of length or of current there corresponded a different form. Only when each separate experiment—and there were hundreds of them—had been carried on for a sufficient length of time could readings of voltage be obtained which were truly normal. Results obtained in this patient way, when plotted out in curves, showed the most surprising regularity. Instead of the broken curves (such as Frölich's, Fig. 2 *supra*) of the earlier observers, curves of smooth outline were obtained. Also the observations had been pushed further. The curves had been carried to extremes—for very large currents and very small currents; to very high voltage and very low voltage; with very short arcs and very long arcs; with very big craters and little craters. Those curves contained by far the most complete account of the natural history of the arc than any other thing attempted by anyone else. I looked forward to the publication of these results with great interest. Sad to relate, the scientific man to whom Prof. Ayrton entrusted the paper before he left America to return home, after keeping them beside him for some months without sending them to press, allowed his negro servant to use them for lighting fires. Only a few fragmentary notes remain. I have urged Prof. Ayrton to renew his labours and repeat investigations of such importance, and I am glad to say that we are likely to have something soon from him to repair the loss. But until that appears I shall feel, at any rate, as though a very large part of the physics of the arc was still wanting.

Note added, October, 1895.—During the course of the current year Mrs. Ayrton has communicated to the *Electrician* a series of papers embodying the fragments of the research of which the records were so shamefully treated, together with the results of renewed experiments. Mrs. Ayrton has further communicated to the British Association, in September, 1895, a paper on the formulæ for expressing the relation between voltage, current, and length of arc. The results of these observations are so important that it would be an injustice to their merits to attempt to summarise them here. Mrs. Ayrton's formula has been added to those exhibited in the table.—S.P.T.

Arc Furnaces.

From the time of De la Rive and of Despretz, experiments have been made on the use of the arc for electrometallurgical

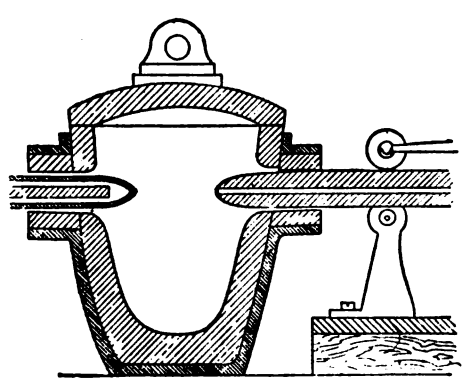

Fig. 9.

processes, owing to its very high temperature and the reducing action of carbon. Napier, in 1845, presented to the Society of Arts an electric furnace intended for the reduction of metals, consisting of a lined plumbago crucible, into which a carbon electrode was introduced. Sir W. Siemens was amongst the first to revive the construction (Fig. 9) of an arc furnace. He introduced, through the sides of a crucible refractory and non-conducting material, two pencils of carbon, between which the arc was formed. Since then great progress has been made by Cowles in the production of aluminium alloys, and by Moissan and others in the reduction of metals. A wide field for commercial development has thereby been opened.

Another thing has to be done—the chemists must go to work. The chemistry of carbon at high temperatures is one of those things that ought really, now that the supply of electricity is so common, to be easy to experiment upon. The electrician provides what the chemist wants: the means of making a high temperature with an arc. What the chemist has not yet worked out is the chemistry of carbon at high temperatures. Thus we know that chemists have not found a compound yet that cannot be decomposed into its elements at the temperature of the arc in the presence of carbon, so that carbon appears to be the nearest approach yet to the universal solvent. When I deal next week with the optics of the arc I shall recur to this matter of the behaviour of carbon itself; but from this point onwards—that is to say, in my next lecture and in the one afterwards—I do not propose to return to any of the other materials that have been proposed. It simply is waste of time at present to deal with arcs made with any other material than carbon; in fact, I will take this one of the 70 known elements, and confine myself to it. And I will deal with that element in a particular way—viz., as used in the making of an arc at about 40 to 50 volts, leaving aside all high-voltage phenomena, all vacuum phenomena, all the abnormal phenomena of the arc, confining myself to the arc as we know it for industrial purposes.

LECTURE II.

Optics of the Arc.

The optical phenomena of the arc are nearly as complicated as are those electrical phenomena which occupied us a week ago. They vary with every different kind of carbon that one may employ, with every different value of current that one may use with a given carbon, and with every different kind of adjustment that one may have in the lamp that regulates the carbon. In a lecture such as this one can only deal with a few salient facts in a few typical cases.

Distribution of Light of the Arc.

The first and most important case to consider is that of the normal arc produced by the continuous current. There are two possible general cases of this also. The first case is that in which the current descends from the upper carbon to the lower, and is generally adopted for the lamps used for outdoor work. The second case, which is rather exceptional, and is only adopted in certain cases of indoor illumination, is that of the inverted arc, where the current ascends from the lower carbon to the upper. As the former is the more usual, we will deal with it. In this lantern we have now an arc formed, the particular regulator employed here being a Serrin lamp of the old-fashioned sort. I use it rather than any more modern mechanism simply because it is convenient as a table lamp. In front of the arc, which is formed here between these carbons, we have a lens in order to project the view of the arc upon the screen, and we can, if need be, introduce in front of the lens an erecting prism to rectify the position of the image on the screen You now see upon the screen the image of the arc formed between the carbons. The positive carbon, with its luminous crater, is at the top; the negative, with its characteristic peak, is at the bottom; and in between them is a violet-coloured flame or arc, consisting of the column of carbon vapour through which the current descends. By a very small adjustment of the upper carbon I arrange the position of the points so as to enable you to get a better view of the crater. Here is the first

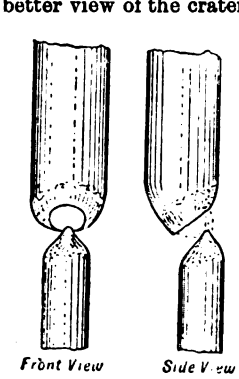

Fig. 10.

and most obvious optical fact, that the light comes from the white-hot surface from which the carbon is evaporating. About 90 per cent. of the light comes from the crater and about 4 or 5 per cent. from the negative peak, while comparatively little light comes from any other part. Around the rim of the crater there is, however, a region that is less luminous, not so

Digitized by Google

hot, and of a redder colour, and there is a certain small percentage of light—not more than 3 or 4 per cent. of the total light at most—emitted from the intermediate flame. Now, of course, there results from this a peculiar distribution of light in the space all round; the light is, in fact, thrown mainly downwards.

When it is desired to throw the light, not symmetrically downwards, but to project more of it in a horizontal direction, we resort to the device, introduced first by Duboscq, of displacing the line of the carbons so that the negative peak instead of being exactly under the centre of the upper carbon is brought a little forward (as in Fig. 10). The crater then forms obliquely, with the negative peak in front of it. This effect I will now produce by simply shifting the upper carbon backwards. As I gradually displace the upper carbon to one side the form of the crater will change; the positive carbon will burn away more on one side than the other. It takes a few minutes to change its shape, during which time the light will be unsteady, and when the new form has been assumed we shall find that the light is thrown mainly on one side, as is desired for projector purposes and for use in the optical lantern. We may have to let the arc burn untouched for something like half an hour in order that the final shape of the surfaces may be properly assumed. As the maximum emission of the light is at right angles from the luminous surface we shall now have obviously a different distribution in the illumination.

Distribution Curves.

For a period of 15 years or more back it has been customary in the laboratory to measure and plot out the amount of light given by arcs in different directions and to study the curves of distribution produced in that way. Two examples of these are shown in Fig. 11. Curve A relates to an arc produced at a

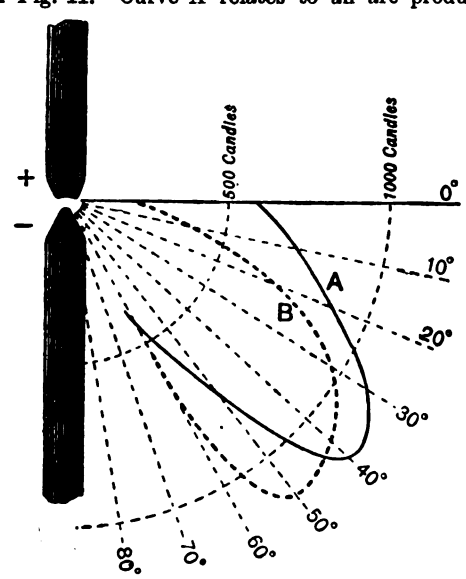

Fig. 11.

constant voltage on a low-pressure system of supply; Curve B to an arc produced with an unvarying current on a high-pressure system of supply, other arcs being in series with the one measured. The mean current for both was about the same. The data of the measurements (which are taken from an American source) are given in the table below.

(A) Low-pressure.		(B) High-pressure.	
Angle, deg.	Candle-power.	Angle, deg.	Candle-power.
0	593·7	0	210·5
10	712·1	10	407·4
20	866·3	20	687·4
30	1,094·0	30	977·1
40	1,183·0	40	1,179·0
50	682·2	50	1,140·0
60	495·4	60	595·7

If we select some photometric arrangement which will enable us to measure the amounts of light given out in different directions horizontally and at different angles downwards, we can then plot out along these angular directions the amount of light so measured. The distribution curve, marked B in Fig. 11, shows that a little light is given out in an absolutely horizontal direction, that is because in that direction the lower rim of the crater throws a little light sideways. At an angle of 10deg. downwards there is a little more light, and at 20, 30, 40, and 50 degrees one finds that there is an increasing amount until you come to the maximum in one particular direction, which, in this case, is about 50deg. from the horizontal. As you go further along you find that the light suddenly diminishes, not absolutely abruptly, but very rapidly, while absolutely straight down there is no light thrown at all. Obviously, in that case, there is no light because the bottom carbon and its holder throw a shadow. The Curve A in Fig. 11 is another plot taken from a different lamp under different circumstances. Let us now compare the curves so plotted with Fig. 12, which shows a plot relating to an alternating-current lamp. In such lamps the two tips do not materially differ in form from one another provided the quality of carbon is alike and the pencils of equal thickness.

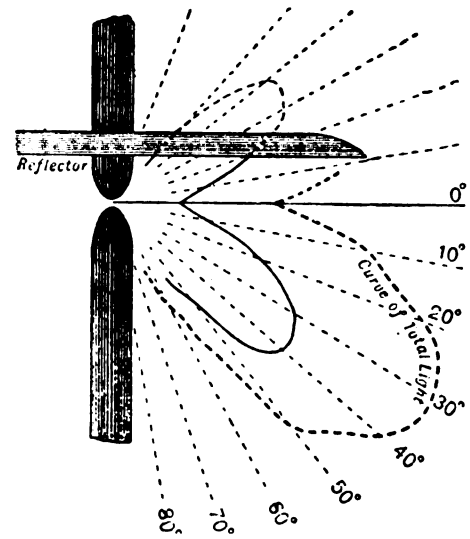

Fig. 12.

Both tips take the form of a blunt peak. This form would be exactly alike were it not for the fact that the hot air ascending at the sides heats the upper carbon more so that it becomes slightly more coned than the lower one. In this case the black curve represents the amount of light in various directions. Some is thrown downwards at an angle and almost an equal amount is thrown upwards at an equal angle with intermediate values in intermediate directions. But if a reflector is interposed to catch the light that is going upwards and throw it also downwards, one obtains the distribution plotted out in the dotted curve.

(To be continued.)

INSULATION OF HIGH-PRESSURE CIRCUITS.

The New York *Electrical Age* of December 7 has published an abstract of a paper read by Captain W. Brophy before the Boston Electric Potential on the insulation of circuits having a difference of potential of over 2,000 volts. After maintaining that all such circuits should be placed underground, Captain Brophy makes some strong remarks on the way in which overhead lines are erected in America. "The so-called insulating covering," he says, "in use at the present time for high-potential overhead circuits is worse than a delusion and a snare. I believe it would be better to hang out the danger signal at once, by using bare copper wire, than to continue the use of this flimsy fraud that affords no protection to human life or property, but lures innocent people on to injury and death. Knowing the worthlessness of the material, it becomes necessary to use the best form of insulating supports." Iron poles Captain Brophy condemns altogether. "They are a relic of barbarism that should be relegated to the scrap heap, and any attempt to patch them up only serves as a thin disguise to the danger that lurks within them. Twenty-five to forty feet of wood between the iron and the ground means that much insulation, while 100ft. of iron only means what the glass insulator, wooden pin, and cross-arm afford. The waste of energy due to the iron poles on the long circuits is simply enormous. Where such circuits are placed on the modern iron and steel structures they become a source of danger to persons who have occasion to handle these or other wires on the same or other fixtures."

DISTRIBUTION OF POWER IN COLLIERIES.*

BY LLEWELYN B ATKINSON AMICE.

The present position of the coal-mining industry in the United Kingdom is one deserving of the most thoughtful consideration by all who are interested in the future commerce of the country, and the object of the present paper is to point out how some of the difficulties under which this industry at present labours may possibly be met. The difficulty to be contended with at present may be briefly stated. The possible output, indeed the output at which a reasonable profit can be earned, is greater than the demand at present prices; and even this demand is threatened by the decreasing price of foreign coal.

* Paper read before the South Wales Institute of Engineers.

Digitized by Google

From whatever point of view it is looked at, the question resolves itself into stimulating demand, and this can only be effectually done by lowering the selling price, which cannot at present be done without extinguishing the profit.

To decrease the cost at the collieries there are, broadly, three courses: (1) to decrease the payment per ton to the mineral owner; (2) to decrease the wages cost per ton raised; (3) to decrease the fuel expenditure per ton raised.

The first of these is a matter outside the scope of this paper, the second will be briefly touched upon, and the third will be dealt with in some detail. In the course of the last eight or nine years the author has been in close contact with mining operations in various parts of England and Wales, and the opinion has gradually been forced upon him that there is a very large margin of economy in wages and fuel to be effected. This arises from the fact that economies in labour and fuel which are studied and insisted on in engineering and manufacturing industries are hardly considered in coal-mining, at all events in the majority of instances. This broad fact must appeal to every mind that, whereas in almost every manufacturing process or industrial operation the product per man has nearly doubled and the consumption of fuel been halved within the last 15 years, in coal-mining the product per man has been practically stationary, and the cost of fuel per ton raised probably nearly so. This is frequently attributed to the stringency of mining legislation, but legislation has largely affected other industries also, and the result cannot be altogether attributed to this cause.

It would be a long task to enumerate the causes which, in the author's opinion, contribute to this result; but, broadly, it appears to him that what is required is to do in mining what has been done in every other department of industry, and to lower the cost of wages and material per ton by increasing the product per man and per pound of fuel by the following means: (1) improved organisation, both in the working, and more especially in the original laying out of the scheme of working a colliery; (2) more superintendence and supervision underground by thoroughly well-informed mining and mechanical engineers; (3) the greater use of mechanical power instead of human and horse labour, and a more economical production of that power. In short, substitute brains and mechanical power for human labour.

It has been already stated that the immediate object of this paper is to deal with the question of the economical production of power, but a few remarks on the subject of mechanical power in collieries may be useful. The getting of coal resolves itself into cutting and filling and hauling to the pit bottom. In the great majority of collieries both cutting and filling are done without using any mechanical power whatever, and the progress made in introducing mechanical coal-cutters is slow, at all events in this country. A considerable experience extending over some years with coal-cutting machines in various collieries and various parts of the country justifies the author in saying that there are hardly any seams under 3ft. 6in. in thickness that could not be more cheaply worked by mechanical coal-cutters than by hand labour, and with a better product of round coal, but that in probably not 5 per cent. of the collieries of the country is the existing organisation of the filling and haulage sufficiently good to enable machines to be worked with that regularity which will make them pay. This is the secret of the otherwise unexplained fact that some few collieries have been and are worked by machinery with marked success, whilst the reverse holds good of the majority of cases in which it has been tried. Organisation and superintendence, those are the only secrets of success in cutting coal by machinery; till they are forthcoming, mechanical assistance in this direction must be postponed. In thin seams much might no doubt be done to apply mechanical power to reduce labour and breakage in filling the coal, but the same remark applies as to coal-cutting. The use of machinery in the coal face would so much reduce the length of face under work for a given output that the roads on to the face being less in total length, could without increased cost be kept in a condition enabling mechanical haulage to be used right up to the face, doing away with horses and ponies altogether. These are some of the directions in which mechanical power may be looked for to profitably enable the output per man to be increased. But before this can be done much will have to be done to improve the general organisation both above and below ground. And this may well be commenced by the economical laying out and conduct of the arrangements for the generation of power above ground.

Consider the conditions under which this is at present carried out. Generally speaking, when sinking operations are completed, a winding-engine is put down. Subsequently, as the workings extend, haulage is considered, and some plant, either steam, compressed air, or electrical, is provided for this. Later, perhaps pumping becomes necessary, and again a plant (perhaps on another system) is put in. There are various engines at the surface for the screening, repairing-shop, and other purposes. All these are of uneconomical types, so there ensues at every point waste of heat, waste of steam, particularly when, as in some cases, separate boilers are put down for each plant. And the answer to any criticism generally takes the form: "Oh, fuel is so cheap at a colliery that it does not matter." Why is the fuel so cheap—that is, of such low value? Because it is so small—smashed in hewing, smashed in filling, smashed on the screens, due to imperfect methods and appliances at every point. But at any rate it is worth at least 2s. 6d. per ton, and it is generally estimated that from 5 per cent. up to even 10 per cent. of the total output by weight of the collieries is consumed at the surface, and this means, even taking the lower figure, about 9½ million tons, worth about £1,190,000 per annum.

In has been stated by Mr. Foster Brown that the probable consumption of coal in colliery engines, taking an average, would be not less than 6lb. per horse-power hour. Taking this to refer to indicated horse-power, it is possible to produce the same power with 1½lb. of coal, or even less, hence it may be fairly said that there is a possible saving to be effected of 75 per cent., worth annually nearly £900,000. It would probably be well within the mark to say that the saving to be effected in labour of handling, and in the maintenance of boilers and appliances for consuming this, would be worth, in addition, say, 65 per cent. of the above sum, showing a possible economy of, say, 1½ millions sterling per annum, a sum equal to over 2 per cent. on the total value of the coal raised, or about 3¾ per cent. of the whole wages annually paid in the mining industries; and if the coal were raised unbroken, so that its value was equal to the average value of the coal sold, these figures would rise to 3 per cent. of the value of the total coal raised, or 6 per cent. of the wages paid.

It may be stated at once that to realise these economies the power required must be produced by compound or triple expansion condensing engines, appliances almost unknown in colliery work, and to do this there is no doubt that the whole power required at the colliery must be produced in one or at most two engines, and distributed with as little loss as possible to the points where power is required. There are various methods of distributing power, but some of them are only applicable to particular cases, or in particular circumstances; the only two of general applicability are compressed air and electricity. Of these, whilst under favourable circumstances compressed air can be made to give a favourable efficiency, its application in mining is discounted by two important considerations of economy. To utilise compressed air with efficiency (1) the pipes must be free from leakage, (2) the air must be heated before being used. These two conditions are practically unrealisable, and hence the efficiency of air transmission in collieries is and must necessarily be low. The cost of plant and extended air-mains is also high. The advantage, therefore, in point of view of first cost and efficiency as a means of distributing power rests with electricity, the economy of the cables compared with the air-mains, and the facility for extension and alterations to the position of the machinery make electricity an ideal means of distributing power.

There is, however, a question to which I must refer—viz., that of safety. This question of safety is one which has from the first introduction of electricity in mining been prominently before engineers; though it may be noted that among those who have had practical experience of its use in mines the objection is rarely raised. In a paper read in 1891 before the Institution of Civil Engineers by the author, in conjunction with Mr. C. W. Atkinson, this question was somewhat fully dealt with, and certain conclusions were arrived at which time and experience have gone to confirm, but, as this question is to some minds still an open one, and as additional experience has added to the knowledge of the subject, it may be well to deal with it again at some length.

There are two distinct questions: (1) the safety of an electric motor, which may spark at the commutator; (2) the safety of a system of cables, which may be ruptured whilst carrying an electric current.

Dealing with the first of these, it has been shown from theoretical considerations and by practical tests that the amount of sparking which exists with electric motors of good construction is unable to ignite firedamp, owing to the fact that the temperature is never sufficiently high, and it is only, therefore, in exceptionally abnormal circumstances, such as a brush falling out of its holder or becoming displaced absolutely on the commutator, that the inflammation of firedamp can be effected; and it has also been shown conclusively by experiment that there are in the market methods of enclosing either the whole machine or the armature and commutator, or the commutator alone, which, even under these abnormal circumstances, entirely prevent either the access of firedamp or the ignition of firedamp outside the machine.

Practical experience is in accord with experiment and with the principles named, and the author knows of no recorded instance where there has been an accident from the use of an electric motor in a coal mine. In connection with this, reference may be made to the question of "commutatorless" motors worked by multiphase alternate currents. As the principles on which these motors work are little understood, the author has appended to this paper some notes on the subject,

Digitized by Google

but a few points are especially worthy of consideration. The first is that although such a motor may have no commutator, if it has to be regulated as to speed, or to start with the load on, it must have brushes and current-collecting rings, in which case the displacement of the brushes under abnormal circumstances may have in a modified proportion the same result as in an ordinary motor. Another circumstance in connection with such motors as at present constructed is that the maximum turning moment they will give has a limiting value, beyond which it decreases as the load increases, even although the current increases, and that at any other than the normal speed the efficiency rapidly falls. Curves are given showing the maximum turning moments given at different speeds, and the efficiencies are shown. For comparison, similar curves are given for a motor in which the speed is controlled by varying the strength of the magnetic field, using continuous current. A further point is that with such motors the losses in the cables and the dynamos, which with continuous currents are proportional to the power transmitted, are not proportional in the case of alternate currents, whilst, in addition, as 250 volts alternating will give the same "shock" as 500 volts continuous, which is generally treated as the maximum advisable in a colliery, the cables have to be of about twice the area of section for the same power; hence these various considerations contribute to this, that the advantage of such motors at full load and full speed are to be balanced against their disadvantages at less than full load and at other speeds, and in the particular case of colliery transmission these points are large factor.

Returning now to the second point in the question of safety—viz., the possible breakage of a cable. This may be at once overcome if the cables are buried below the surface, but as this method has the disadvantage of expense, and frequently of deterioration of the cable, we may consider the case of a cable hung from the walls or timbers. In this case, if the cable does break, the ends are quickly parted, the spark may continue for the fraction of a second, but it has been shown by the experiments of Messrs. Wüllner and Lehmann at Aix-la-Chapelle, which experiments were accepted as conclusive by the Prussian Firedamp Commission, "that even violent sparks from rupture of the current, accompanied with the explosion of fragments of iron in a state of combustion, had no effect on the inflammation of firedamp." Considerable light has, in the author's opinion, been thrown on this question by the facts recently stated by Prof. Vivian B. Lewis. It appears that the ignition of firedamp arises in most cases, not from the raising of the temperature to the ignition point of firedamp, which is very high, but by the raising of it to the point of its decomposition with evolution of hydrogen, which, becoming ignited, eventually ignites the firedamp. This requires two things: (1) time (and Prof. V. Lewis states that 10 seconds is in some cases necessary); (2) the maintaining of a particular mass of gas in contact with the point where the heat is developed long enough to effect the operation quoted. Neither at the commutator of a motor, nor at the point of rupture of a cable, are these conditions fulfilled. In the face of the facts and experiments and experience now at disposal, those who raise the objection to electricity in mining on the ground of safety ought, in the author's opinion, to bring some proofs of that danger if it is to receive consideration. Notwithstanding the extended use of electricity, these causes of accidents do not occur, and, in the opinion of many well qualified to give it, the danger arising from electricity is less than that arising from safety lamps, and enormously less than that arising from almost any explosive agent now in daily use.

Having dealt with this question, it remains to be asked, Is the present position of power distribution by electricity such that we may use it with confidence for the whole of the power required at a colliery? The author's answer to this is, Yes. In support of this may be given the following facts: The largest engine at a colliery is the winding-engine; and suppose this to require to be capable of developing power at full speed of 1,000 h.p., which is an outside figure, this could be well replaced by two motors of 500 h.p., one at each end of the shaft of the drum, without gearing. There are numerous cases of dynamos and motors of this power working with ease and satisfaction, and giving no difficulty whatever, and operated by ordinary mechanics with no more trouble than an ordinary steam-engine. Motors of smaller sizes are in use all over the world, with universal satisfaction as to ease of manipulation and low cost of maintenance.

Are the claims made for efficiency of electric distribution of power realised? On this point the author has examined carefully tests made by himself and by others on electric power plants, and has arrived at this conclusion—whilst the efficiency of distributing electric power and its utilisation in the motors does come up to that claimed, the efficiency of the production of electricity is not as a rule as high as is claimed or as high as may be realised, and the reason is this: sufficient account is not taken of the fact that the average load is considerably less than the maximum requirement, and the curve given—which is taken from an actual test of a direct-coupled engine and dynamo—will show how this operates. Whilst the efficiency of electric generation—that is, the proportion between the electric power delivered to the cables and the indicated horse-power of the engine—is as high as 86 per cent. at full load, it falls to 74 per cent. at half-load and to about 58 per cent. at one-quarter load. The reason for this is to be found in the power the engine takes to drive itself. The engine is generally arranged to work with an economical cut-off at the full load or maximum power, and consequently is larger than necessary for all smaller loads. It should be arranged to work with an economical cut-off at the average power, then at a larger power; although the consumption of steam per indicated horse-power would be somewhat greater, the mechanical efficiency would be so much better at the average load that considerable economy and, indeed, the best possible result would be obtained. The moral is to use engines with automatic expansion valves, permitting the engine to work with a cut-off as $\frac{1}{2}$ or $\frac{5}{8}$ of the total cylinder volume when developing the maximum power, and working with a more economical grade of expansion at the average load.

To apply the principles advocated in this paper, the method to be adopted should be as follows: When a colliery is opened an estimate must be made of the power which will ultimately be required for the whole colliery. It need not be all provided for at once, but the arrangements must be such that what is provided will be worked at an economical load, and that by simple duplication it may be increased. An example is given below which may be considered to represent an average case where there is no very heavy pumping.

TABLE OF POWER REQUIRED AT A COLLIERY.

	Maximum power. H.P.	Average power. H.P.	Minimum power. H.P.
Winding	700	225	0
Fan engine	60	60	60
Pumps	50	50	50
Haulage	200	100	0
Lighting	20	10	10
Screens	20	20	20
Shops at surface	20	5	5
Capstans for wagon handling	20	10	10
Total	1,090	480	155

The power required by the winding and haulage engines are what would probably be required in a colliery drawing about 1,500 tons per day, and the maximum power required by the winding-engine is reckoned on the assumption that the weight of the ropes is unbalanced, and the average on the assumption that the winding takes 40 seconds and the unloading and loading 25 seconds. Variations will correspondingly affect these points, and must be made to suit each case. These powers set down are those required at the separate machines, and if we take it that the loss in the cables at full load is 5 per cent., which will be ample, as the bulk of the power is not far from the source, and that at the average load and upwards the indicated power is as shown on the curve (steam dynamo efficiency)—that is, 100/86 of the power delivered to the cables, we get the following as the indicated power required at each load, which, assuming that the electric motor will transform only as much electric power into mechanical power as a steam-engine would convert of indicated power into mechanical power, gives a direct comparison between the actual indicated power required if all the engines were worked direct from the boiler, or by the distribution thus to be effected.

INDICATED HORSE-POWER OF GENERATING ENGINES.

Maximum.	Average.	Minimum.
$\frac{100}{86} \times \frac{100}{95} \times 1{,}090$	$\frac{100}{86} \times \frac{100}{97{\cdot}5} \times 480$	$\frac{100}{64} \times \frac{100}{95} \times 155$
1,330	572	265

Now it will be observed that the average power is 572 i.h.p. as compared with 480 i.h.p. actually required at the engines. But taking for the former Mr. Foster Brown's figure of 6lb., and for the latter 1½lb., the economy resulting is found from the fraction:

$$\frac{6}{1{\cdot}5 \times \frac{5}{4}\frac{1}{6}\frac{2}{0}} \text{ or } \frac{6}{1{\cdot}78} \text{ or } \frac{100}{29{\cdot}6},$$

not far differing from the possible economy spoken of early in the paper.

That such figures are realisable in practice is shown by the figures given in a paper read before the North of England Institute of Mining Engineers by Mr. Alexander Siemens, and published in Vol. 8, Part 2, of the *Transactions* of the Federated Institute of Mining Engineers. Tests are there recorded where, with a plant considerably smaller than that here considered, a consumption of 2·62lb. per electrical horse-power hour, equivalent to 2·25lb. per indicated horse-power hour, were obtained; and in the discussion on the same paper reference was made by Mr. D. B. Morrison to a plant using 2lb. coal per electrical horse-power hour, equivalent to 1·72 per indicated horse-power.

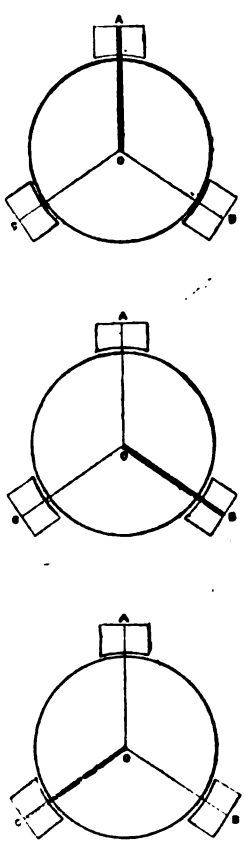
The writer is aware that in thus advocating the generation of the whole of the power in one engine or pair of engines he is advising a very radical departure from existing and well-tried

Digitized by Google

methods ; but the advantage in economy is so great that in his view a revision of method must take place, and in any case the subject is well worthy of consideration and discussion.

Notes on the Fundamental Principles of Multiphase Electric Motors.

The principles on which the action of these motors depend may be explained in general terms as follows—the explanation referring in particular to a three-phase system. Suppose in Figs. 1, 2, 3, there are three electromagnets radially fixed in positions O A, O B, O C. Suppose, by means which need not be gone into, they are magnetised in rotation—that is, first, as in Fig. 1, O A. There will then be a magnetic axis, O A. As O A is demagnetised, let O B be magnetised, the magnetic axis has reached O B. Repeat this with O C, and finally again with O A. The magnetic axis has been in each of the positions O A, O B, O C, and now is at O A. This result is the same as if O A only existed and had been mechanically rotated round the point O one revolution.



Figs. 1, 2, and 3.

cylinder. For instance, a turning moment of 1,820lb.-feet is given at about 88 per cent. of the full speed with no resistance in circuit. The same turning moment is given at 68 per cent. with some resistance added, and at 10 to 15 per cent. with a maximum of resistance. Taking the working load of this motor to correspond to 1,300lb.-feet turning moment, the efficiency curve of such a motor is shown at the right-hand side of the same plate. This curve is only an approximation, but will not differ much from the actual curve. The curve of current used is taken from tests of a three-phase motor made by the Allgemeine Elektricitäts-Gesellschaft (Berlin), and shows that when the power falls from 100 to 0 the current falls from 100 to 40, the speed being the normal speed of the motor. Fig. 4 shows comparative curves for a continuous-current motor, with field-magnet regulation, the supply being at constant pressure. It is assumed that the magnet strength may be doubled, taking that required to give the full output of the armature at normal speed as unity. The curve of turning moment of such a motor (Fig. 5) may be made a straight line at any speed between 100

Fig. 5.

It was shown by Arago as long ago as 1826 that if a magnet is rotated round a conducting body, such as a copper plate or cylinder, electric currents are produced in the conducting body, which currents attract the rotating magnet, and thus the conducting body is dragged by the rotating magnet. If, therefore, there is a cylinder of copper or of iron covered with copper conductors surrounded by such magnets, through which the current is in turn passed, producing a rotating magnetic axis, the cylinder will rotate. In practical working the currents are made to rise and fall in each magnet by using alternate currents—that is, currents rising and falling in the circuit—and arranging them so that the maxima in each of the circuits follow one another in the order described, and hence the name multiphase, for the phase of the current in each circuit differs.

Curves showing the turning moment (torque) exerted by a three-phase motor, copied from an article on "Electric Traction" by Philip Dawson, are given. The ordinates show the speed of the motor expressed as percentages of the full speed taken as 100. The abscissæ show the turning moment in pounds at 1ft. radius. The three curves show the effect of adding resistance to the circuits of the conductors on the rotating

per cent. and 50 per cent. of the normal speed, and, by inserting resistance in the armature circuit at any speed below this, it may be regulated to have any value at any speed, only defined by the ultimate current the armature will carry without burning up or mechanical breakdown. The efficiency at full turning moment by regulating the field will remain about 92 per cent. at all speeds down to 50 per cent. of the normal speed, after which it will fall with the speed. The current will at full speed be proportional almost exactly to the work done. The curves given are typical, to allow of comparison with the three-phase motor, and do not refer to a particular motor.

Almanacs, Diaries, etc.—The Brush Electrical Engineering Company, Limited, forward us a neatly-bound "Walker's No. 1 Diary" for 1896 ; John Heywood sends us "Calvert's Mechanics Almanack," which has now reached its twenty-third year of publication ; while from the offices of the *Indian and Eastern Engineer* we have received the useful quarto "Diary" for 1896 affiliated to that journal—a new feature of which is the table of conversion of English and metric weights and measures.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Orduna.—The municipal authorities invite tenders for the execution of a waterworks and electric lighting scheme. The estimate is 84,729 pesetas. Particulars of El Ayuntamiento de Orduna, Spain.

Betanzos.—Tenders are invited by December 28 for the concession of the electric lighting for 25 years of the town of Betanzos, Spain. Conditions of La Direccion General de las Administraciones Locales, Madrid.

Ploesti.—The Municipality of Ploesti invites tenders by January 15 for the lighting by electricity of the 46 principal streets in the centre of the town. Conditions from La Mairie de Ploesti, Roumania.

Brussels.—The Ministère de la Guerre invites tenders by January 15 for (1) a heating installation, (2) electric lighting in the new military school to be constructed in the Avenue de la Renaissance, Brussels.

Langeac.—The municipal authorities invite tenders for lighting the town by electricity during a period of 40 years. Water power is available. Specifications of M. Grenier, conducteur des Ponts-et-Chaussées à Langeac (Haute-Loire), France.

Aussig.—The communal authorities propose to have built a seven-mile single-line tramway. The choice of system is left open. Contractors are invited to place themselves in communication with the Stadtrath, Aussig-a.-d.-Elbe, Prussia. Tenders are to be in by January 31.

Pernambuco.—Tenders for lighting the city of Pernambuco by electricity are invited by the Government of the State of Pernambuco (Brazil). Particulars may be had on application to the Brazilian Consulate-General, Liverpool, or to the Brazilian Consulates in London, Manchester, and Glasgow.

Dublin.—Messrs. Arnott and Co., Limited, Dublin, invite tenders from competent firms for electric light and power installation to their new premises, Henry-street and Princes-street, Dublin. A copy of specification can be obtained from Mr. George P. Beater, M.R.I.A.I., architect, 17, Lower Sackville street, Dublin, on payment of £5. 5s., which will be returned on receipt of bona fide tender, which must be delivered at architect's office on or before January 8, 1896, endorsed "Electric Installation, Arnott and Co., Limited.

Chelsea.—The Guardians of St. Luke, Chelsea, invite tenders for fitting up an electrical wiring installation, with fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. Particulars upon application to the Guardians' architects, Messrs. Lansdell and Harrison, 12, Compton-terrace, Highbury, N., on depositing with them £5, which will be returned to those sending bona fide tenders not later than 12 o'clock noon on December 31, 1895. addressed to Mr. Wm. Miller, clerk to the Guardians, Guardians' Offices, 250, King's-road, Chelsea, S W.

Durban (Natal).—The Corporation desire tenders for the supply, for delivery at Durban. and fixing at Durban, of steam and electrical plant for the lighting of the borough by electricity. The work will be executed under the direction of Mr. Fletcher (borough engineer) and Mr. Hadfield (electrical engineer) at Durban. The plant required includes high-speed engines, dynamos, cables, arc and other lamps, accumulators, etc. Specifications and plans can be obtained from Mr. W. H. Radford, C.E., Angel-row, Nottingham, consulting engineer to the Corporation, on deposit of £5. 5s., which will be returned on receipt of a bona fide tender. Sealed and endorsed tenders, in duplicate, must be delivered at the offices of Messrs. Webster, Steel, and Co., agents to the Durban Corporation, 5, East India-avenue, Leadenhall-street, London, E.C , by 28th inst.

RESULTS OF TENDERS.

Newport.—The Free Library Committee have accepted the tender for an electric installation in the free library submitted by Messrs. Alger, of Newport, at £147, less £10 for old material.

Kingston-on-Thames.—The Corporation have accepted the tender of Mr. Mark Bell, at £19. 10s., for fixing guards round the machinery at the electric lighting works, as required by the Board of Trade inspector.

Leyton (Essex).—The Urban District Council have received the following tenders in connection with the projected electric lighting installation:

Buildings, machinery, foundations, water-tank, piping, drains, etc.

J. Holland	£2,976 0 0
H. J. Carter	2 586 18 3
H R. Rous (accepted)	2,394 14 7

Dynamos, switchboards, balancing transformers, wiring buildings, etc.

Holmes and Co.	1,726 10 0
Johnson and Phillips	1 602 6 0
Thames Ironworks Company	1,502 7 6
Brush Electrical Engineering Company	1,492 0 6
India Rubber, etc., Telegraph Works Company	1,479 8 2
Siemens Bros. and Co.	1,478 7 0
Laurence, Scott, and Co , Limited	1,411 5 0
Wigston Electrical Engineering Company	1,371 6 0
Crompton and Co., Limited	1,339 12 0
Electric Construction Company (accepted)	1,330 7 2
Nalder and Harrison Construction Syndicate	1,163 0 6

Gas producing plant.

Dowson Economic Gas and Power Company, Limited (accepted)	854 15 0

Gas-engines, piping, etc.

Crossley Bros.	1,342 14 0
Bilbie, Hobson, and Co.	1,523 0 0
Wells Bros.	1,144 6 0
C. L. Ritchie (part contract)	174 0 0

Storage batteries and cable connections.

Hedland Electric Storage Battery Company	1,113 0 0
Johnson and Phillips	1,082 10 0
Epstein Electric Accumulator Company	844 16 1
Conze and Simon	818 16 0
Electrical Storage Company, Limited	754 5 10
Pescatore (accepted)	748 4 6
Pritchett and Gould	632 16 6

Mains, including all trench work, cables, and conduits.

India Rubber, etc., Telegraph Works Company	11.354 15 10
Henley's Telegraph Works Company, Limited	10,286 11 10
Wigston Electrical Engineering Company, Limited	9,920 13 4
Glover and Co.	9 646 5 1
British Insulated Wire Company, Limited	9,380 15 5
Fowler-Waring Cables Company, Limited	9,295 16 2
Callender's Bitumen Telegraph and Waterproof Company	9,240 14 1
Siemens Bros. and Co (accepted)	8 996 1 6

BUSINESS NOTES.

Burnham (Essex).—The Lighting Act has been adopted for the whole parish.

Kingstown.—The Town Commissioners have sealed the application to the Board of Trade for a provisional order for electric lighting.

Folkestone.—The Town Council have approved the draft of the provisional order for electric lighting. The maximum expenditure is fixed at £50,000.

Leeds.—The Varley Mills at Stanningley, which are now leased by the Leigh Mills Company, of Coventry and Bradford, have been lighted throughout with electricity

Anglo-Portuguese Telephone Company, Limited.—Coupons No. 16 of the first mortgage and No 11 of the second mortgage debentures will be paid, less income tax, by Parr's Alliance Bank on and after January 1.

Lynn.—The Town Council have sealed the memorial to the Board of Trade asking for an electric lighting provisional order, and the proposed compulsory area for lighting has been enlarged to include Norfolk street.

National Telephone Company, Limited.—The transfer books of the 3½ per cent. debenture stock are closed from Monday to 31st inst. inclusive, for the preparation of the warrants for the half-year's interest due to January 1.

Coventry.—The Town Council have decided to instal the electric light in the free public library and to provide the cost out of the borough fund, it being reported that irreparable damage had already been done to valuable books by gas.

West Coast of America Telegraph Company.—The coupons due the 31st inst. on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street, London, E.C., and should be left three clear days for examination.

Newmarket.—The Urban District Council have received a letter from the Newmarket Electric Lighting Company asking the consent of the Council to their provisional order. It was decided to let the matter stand over until the next meeting.

Hobart Electric Tramway Company Limited.—Mr. G. Carnaby Harrower, College-hill-chambers, E C., has resigned his position as manager in London of this Company, and the offices have been removed to Mansion House-chambers, E.C.

Brighton.—The Watch Committee have resolved that the electric light be installed in the Level Police Station and the police offices at the Town Hall, and Mr. Wright was instructed to obtain tenders from local electrical engineers for carrying out the work.

Barnsley.—The Houghton Main Colliery Company, Barnsley, Yorks., have just had put down by Messrs Crompton and Co., of Mansion House-buildings, London, an electrical plant for lighting the whole of the surface, including the head offices weigh-houses, workshops, engine houses, screens, and the pit yard.

Bridgwater.—In the course of a discussion on the lighting of the cattle market, it was stated that the Corporation had adopted a suggestion made by the Lighting Committee to appoint a small committee to consider the whole question of the lighting of the town as regards electricity or the taking over the gasworks.

City and South London Railway.—The returns for the week ended December 22 were £1 013, compared with £968 for the corresponding period of 1894, being an increase of £45. The total receipts for the half-year 1895 were £22,553, compared with £22,447 for the corresponding period of 1894, being an increase of £106.

Dewsbury.—The directors of the Heckmondwike Collieries, Limited, have placed an order with Messrs A. Hirst and Son, electrical engineers, Crescent Works, Dewsbury, for an electric

Digitized by Google

pumping plant for their Park Farm Colliery. The order comprises engine, dynamo, two motors, and two sets of triple-ram pumps, and about 1¼ miles of cable.

Dunfermline. — The Dunfermline Town Council recently adopted the Gas Supply (Scotland) Act, with a view to negotiating with the Dunfermline Gaslight Company for the purchase of the Dunfermline gasworks, but a remonstrance against the adoption of the Act has been lodged with the town clerk by a section of ratepayers, and this will necessitate a *plébiscite*.

Electric and General Exploring Syndicate, Limited —This Company has been registered with a capital of £5,000 in £1 shares. Object: to acquire any lands, buildings, hereditaments, stocks, shares, etc., to develop and turn to account the same in such manner as the Company shall see fit, and to carry on all kinds of agency business. No names of directors are given.

Dover.—The Electricity Supply Company announce that from the commencement of the New Year their charges will be reduced to an average of 6d. per Board of Trade unit, which means that an 8-c.p. light will cost for one hour per day throughout the month 6d. only. It is stated that the company have obtained an order to light the Lord Warden Hotel and other large buildings.

Disley (Cheshire).—The Rural District Council have discussed the adoption of the Lighting and Watching Act without the sanction of the parish meeting. Nothing beyond getting the information about the cost of the lamps required, etc , could be done, and this it was decided to obtain from a number of local authorities. The chairman expressed himself strongly in favour of electricity being used.

New Electric Light Syndicate, Limited.—This Company has been registered with a capital of £2,000 in £1 shares. Object: to enter into an agreement, made December 3, with B. F. de Margenstein, and to carry on, in the United Kingdon or elsewhere, the business of dealers in electric batteries, lamps, switches, etc. The directors are A. C. Miles and the Hon. C. Bingham. Registered office: 268, Strand.

Salt Lake and Ogden Gas and Electric Light Company, Limited.—The Gas, Water, and General Investment Trust, Limited, give notice that the coupons of the 6 per cent. first mortgage gold bonds of the Salt Lake and Ogden Gas and Electric Light Company due on January 1 next will be paid at the National Provincial Bank of England, Limited, 112, Bishopsgate-street, E.C., or at the Farmers' Loan and Trust Company of New York.

Portsmouth.—There is talk of lighting the Portsmouth hospital with electricity. The value of the light in the operating-room would be considerable, and its use in the sick wards would tend to keep the atmosphere purer. Specifications for carrying out an experimental installation in the accident and casualty wards and in the new building in course of erection for the accommodation of the nurses will be submitted and fully discussed at the next meeting of the committee.

Bradford.—From the abstract of the Corporation accounts issued by the borough accountant, Mr. G. A. Thorpe, it appears that the electricity works revenue account for the past year shows a gross income of £11 737, and expenditure £5,773, leaving a trade profit of £5,964. Against this, interest and sinking fund, £4,095, leave £1,869 to be carried to net revenue account This is further charged for depreciation of plant and machinery £1,063, and the net profit is shown at £146 for the year.

Mile End (London).—The Guardians are contemplating lighting their institutions by electricity, and a committee has been making enquiries of other Guardians as to its advantages or otherwise in point of cost and convenience over gas. The Guardians have decided to appoint a consulting electrician, and a committee appointed for the purpose brought up at the last meeting five candidates which they had selected for the post. These having been interviewed by the Board, Mr. Jenkinson was elected.

Grimsby.—The Public Lighting Committee having met to elect a new chairman, Mr. Shephard asked what had been done by the Electric Lighting Sub-Committee. Mr. Curry replied that they had not yet concluded their enquiries, but they would be able to save £50 per year from the lamps they intended doing away with. The outlay for providing light for the lamps suggested, accumulators, etc., he thought would be about £400, and other members referred to the present dynamo not being expected to stand for a much longer time.

Electric Cranes.—Mr. Thomas Smith, of the Old Foundry, Rodley, has constructed an electric overhead traveller capable of lifting, lowering, and travelling with loads of 10 tons on a span of 42ft. The hoisting motion is double-purchase spur gearing, controlled by double friction cones. The drum having spiral grooves, the pulley in the block is grooved to suit the chain. The block has an iron swivel hook. A powerful friction brake is provided and controlled by a screw lever with a handwheel. The crane is driven by an electric motor.

Calne (Wilts.).—On a discussion occurring in the Town Council on the lighting of the public hall, Mr. Bownas said that the electric light question should be taken up, seeing that they had a stream of water close to the hall. Mr. Maundrell remarked that an experienced electrician would be in the town in a few days, and perhaps the Council would like his opinion as to the feasibility of taking up the electric light question. This the Council decided would be the best thing to do, and they voted the sum of £1. 1s. as a fee for the information.

Bournemouth.—The Town Council have referred back to committee an application from Messrs. Tyrell and Sons to put up electric light columns in the front of their premises. The Lighting Committee recommended six columns, the design to be approved, the lights to be kept in all the time the public lights are lit, and with the right of the Council to withdraw at any time. At a meeting of the Lighting Committee the surveyor reported verbally that there had been an accident at a transformer-box in Poole-road, and it was recommended that the surveyor be instructed to ascertain further particulars and communicate with the Board of Trade.

New Appointments —Messrs. P. R. Jackson and Co , Limited, of the Salford Rolling Mills, Manchester, have just made the following additions to their staff: Mr. W. H. Ravenshaw, A.M.I.C.E. (of Booth and Ravenshaw, 110 Cannon-street, London, E C.), as consulting electrical engineer; Mr. E. J. Blandy, A.M.I.C E, as representative in South Wales and the Midland Counties; Mr. A. M. Shepherd, of 32, Albany-road, Ealing, W., as representative in London and Southern Counties; Mr. W. F. Jones (late of Easton, Anderson, and Goolden) as assistant engineer; and Mr. Felix J. Howitt (late of the Norwich Electricity Supply Company), as assistant electrical engineer.

Worthing —Considerable alarm was created in Worthing on Monday night, when, at about eight o'clock, the whole of the gas-lights were suddenly extinguished and the streets remained in darkness through the night. Shopkeepers hastily put up their shutters, hundreds of persons hurried as fast as the condition of the thoroughfares would permit to the gasworks, the news spreading in all directions that they were on fire. A great flare of light immediately over the works intensified the public alarm. The hasty despatch of the fire-engine confirmed the truth of the rumour. Fortunately, however, the fire, which had been caused by an explosion in the governor-house, was soon subdued and the gas was turned off.

Cardiff.—The Lighting Committee of the Town Council have passed the following resolution expressing their appreciation of the services of Mr. W. H. Massey, consulting electrical engineer: "This committee desire to place on record their appreciation of the valuable and important services rendered to the town of Cardiff by Mr. W. H. Massey, M.I C.E., as consulting engineer in connection with the laying down of the system of electric lighting within the borough under the Cardiff Electric Lighting Order, 1891, and also to convey to Mr. Massey their sincere thanks for the conspicuous ability displayed by him in the carrying out of this great work, and of the many intricate and important details in connection therewith."

Swadlincote (Derbyshire) —It was announced at the Urban Council meeting, with regard to electric lighting at Stanton, that Mr. Johnson, on behalf of Lord Carnarvon, had consented to light from 16 to 50 lamps of 32 c.p. each at £1. 5s. per lamp, the lamps to be kept lighted from half-an hour after sunset to 11 p.m from September 1 in each year to April 30 following, the arrangement to continue for 10 years if the Council require it so long. The committee therefore recommended that Stanton be lighted by electricity, and that Lord Carnarvon's offer be accepted, the lamps to be fixed from the colliery to the Board schools and past Mr. Wright's house, and that tenders be invited for carrying out the works. The report was adopted.

Newcastle-on-Tyne.—The Newcastle City Council have again had the tramways question before them, when a resolution was moved to the effect that a petition be presented to Parliament for leave to bring in a Bill for the extension of the system, with power to work the new sections by cables, electricity, or other motive power. Some of the members complained that the petition said nothing as to the working of the trams by the municipality. The Town Clerk said the Council had already decided against that course, The only municipality that had obtained that power was Glasgow, and Newcastle could not ask for the power in the present position, although it might do so afterwards. The resolution was carried.

Glasgow.—The Town Council have discussed a recommendation by the Committee on Electric Lighting to appoint a sub-committee to co-operate and take such action as they might deem expedient, in conjunction with the special sub-committee of the Watching and Lighting Committee, to consider the question of electric lighting, and particularly what kind of lamp should be used. Mr. W. F. Anderson said he had marked that part of the minutes, not knowing but that it might mean a deputation of six members of Council, and probably three officials, to go anywhere or everywhere gathering information about electric lighting. This deputation business was becoming a scandal. After further discussion the matter was sent back to the committee.

Tottenham (Middlesex).—The General Purposes Committee have reported to the Urban District Council that they had a preliminary interview with Mr. Hastings Medhurst, M I.E E, of Victoria-street, S.W., with whom they had generally discussed the question of electric lighting in connection with the provision of a dust destructor. The committee unanimously recommended the Council to employ Mr. Medhurst to prepare reports upon the question of electric lighting and the provision of a refuse destructor for the district separately and combined at an inclusive fee of 50 guineas, this fee merging into his commission providing the Council decided to employ him to superintend the works. After a long discussion the report was agreed to.

Chiswick (Middlesex).—The District Council have received a letter from the Bourne-Grant Electric Lighting Company, stating that they had expected to commence the erection of the electric light station at the beginning of the year. They were prepared to commence the shaft forthwith and understood that the difficulty as to the destructor had been obviated. The clerk stated, in reference to this matter, that he had called at the office of Messrs. Currey and Co., the agents to the Duke of Devonshire, and they

Digitized by Google

were not at present able to return the agreement as to the erection of the electric lighting works and dust destructor. The letter was referred to the Works Committee, and it was decided to write to the Duke of Devonshire calling his attention to the delay complained of.

Tunbridge Wells.—A local paper says: "Several additions are daily being made to the list of customers for the electric light, and it is now to be installed in the Kentish Hotel. This will be a great benefit to the town, as we have had several instances of visitors who have gone to Eastbourne and other resorts because being used to the convenience of the electric light they could not do without it and therefore would not stop at Tunbridge Wells. We hope that other hotels will follow the example of the Kentish, as this will have an important effect in attracting visitors to the town. During the present week Shandon, the residence of the Mayor, and Dunorlan, the residence of B. H. Collins, Esq., have had the light installed. Mr. Gallard is also installing the light in all new houses that he is building."

Telescopic Ladders.—Messrs. J. H Heathman and Co., of Endell-street, London, W.C., seem to keep *au fait* with electric lighting requirements. They are always endeavouring to improve the details of their patent telescopic ladders, trestles, steps, tower ladders and scaffolds, so that they may be economically employed for installing and maintaining electric lamps Five of their tower ladders are, we are informed, used in the streets of Edinburgh, while at Tunbridge Wells Mr. Boot says Heathman's improved Brighton-pattern carriage ladder admirably suits their hilly roads, and Messrs. Frank Suter and Co. wrote this firm that a telescopic tower ladder purchased for the contract of installing electric lighting in the Nottingham art galleries saved more than its cost on the contract.

Liverpool.—The Lighting Committee of the City Council have discussed the estimates for the ensuing year, and it is believed that the new Council will entirely approve of the decisions arrived at, although they will involve extra expense. The committee determined to provide sufficient light, not only in the courts and alleys of Liverpool, but in the main arteries of the city, thus affording the necessary protection to the public throughout the night. Moreover, arrangements have been made in the estimates for the better lighting of the extended areas, though it should, in justice to the Toxteth authority, be said that the lighting in that township needs no improvement, the requirements being more than fulfilled. A considerable addition to the number of hours will be made in each of the other district.

Electric Lighting in West Australia.—The eighth annual dinner of the workmen of Messrs. J. H Holmes and Co., electrical engineers, Newcastle, has been held. Replying to the toast of the firm, Mr. Ellwood Holmes regretted that his brother had been unable to join them that night, having been called away to Manchester, but they would be interested in knowing that he had gone to see a gentleman from the Perth Gas Company of Western Australia, with whom the firm had just completed a contract of about £5,000 for the supply of dynamos, engines, and boilers This showed what a very go-ahead class of men they had in the Colonies, when such a company as the Perth Gas Company had begun to undertake electric lighting as well as the supply of gas. They sold gas he believed, at 12s. 6d or 15s per 1,000ft, about 10 times the price it was in Newcastle, and now had undertaken the supply of electricity. It was a very good sign to see the Colonies taking up electricity in the manner they were doing.

British Electrozone Corporation, Limited —This Company has been registered with a capital of £250,000 in shares of £5 each. Object: to adopt and carry into effect an agreement, made December 9, between John A. Barham and W. Digby of the one part and F. W. Manley, on behalf of this Company, of the other part; to acquire any letters patent, patent rights, concessions, protective trade marks, designs, and copyrights in connection with Woolf's electrolysing, bleaching, and disinfecting process in the United Kingdom, and in any colony and dependency of the United Kingdom, and in any foreign country other than the United States of America and the Hawaiian Islands, and generally to carry on business as manufacturers, merchants contractors, and engineers, etc. The signatories to the memorandum of association are: A. C. C. Todd, Trafalgar-buildings, Charing Cross; J. D. Jehu, Holly Lodge, Keston, Kent; G. Hazelgrove, Chesterton, Clifton-road, Wellington, Surrey; A. J. Lusty, Goldhurst-mansions, Goldhurst-terrace, Finchley-road, N.W.; A. Riding, Wesleyan Training College, Westminster; A E. Griesbach, 17, Gloster-road, Kew; E. H. Selby, 8, Buckingham-street, W.C.

Preston.—At the monthly meeting of the Preston Town Council Councillor M. B. Copland moved the adoption of a recommendation from the Markets and Town Hall Committee, "that the Town Hall and Public Hall be lighted by electricity, at the estimated cost of £2,024." Councillor Healey supported the motion, and Alderman Edelston said that, although he would have liked to see the electric light, he must, under the circumstances, oppose the motion Preston was not a poor town; it was, apart from the Ribble scheme, a rich town. But they had the Ribble scheme, and they had to make the best of it, and provide for it at any cost. An amendment that the matter be referred back was carried by 21 votes to 9. In connection with the electric lighting scheme, the National Electric Supply Company, Limited, have written to a local paper: "Dr. Hopkinson, who has been retained by the Corporation to advise them on the subject, has given them his unbiassed opinion as to the cost of current, which verifies and substantiates what we claim to be the correct comparison between the cost of electric light and gas in Preston. He advises 'that, given a supply of electricity at the normal cost per unit (6d.), and no more light provided than at present, the cost of the supply of electricity will be the same as the present supply of gas.' We would, however, point out that at 4½d. per unit (the price offered to the Corporation) they would find the cost to be 25 per cent. less than they now pay for gas for an equivalent amount of light."

Swansea.—The Streets Committee have considered an application from the National Telephone Company, Limited, for permission to lay three 3in. iron pipes, with manholes, etc, for carrying telephone wires under the pavements from the Central Exchange, Wind-street, to a pole in the grounds of the Royal Institution, and the borough surveyor was instructed to communicate with Mr. Manville, the electrical engineer, as to whether the proposal would in any way affect the intended system of electric lighting and traction. In accordance with notice of motion, Alderman Leeder has moved in the Town Council "That nothing further be done with the scheme of electric lighting until a public meeting has been held." Alderman Leeder said his object was if possible, to have a meeting at which the gentlemen who believed in the scheme would have an opportunity of thoroughly explaining it to the ratepayers, who could then form their opinions and make up their minds before they were asked to pass the statutory resolutions The Mayor remarked there was little or no expense likely to be incurred within the next couple of weeks, and in view of the Christmas season it was his intention to have a meeting called in the middle of January, when the ratepayers would have an opportunity of expressing their views on the matter. Although they had received tenders for the erection of the electric light station and dust destructor, they had not yet been opened, and it was not their intention to open them until the final vote had been taken on the purchase of the tramways, because one thing must stand or fall by the other. It was ultimately agreed that there should be a preliminary meeting of the ratepayers before the formal meeting to pass the statutory resolution.

Eccles (Lancs.).—The Town Council in committee have received a deputation from the Property Owners' Association to make a representation in opposition to the adoption of the electric system of lighting. Subsequently the town clerk laid before the Council the information he had obtained from those boroughs in the kingdom which had adopted the electric lighting system Of these there were 115, and 69 of these were in the hands of the municipal corporations. There were, in addition, 13 or 14 works projected or in course of construction, and Alderman Kendall moved the adoption of the deferred proceedings of the Town Hall and Electric Lighting Committee of November 26 last, and that the corporate seal should be attached to a contract in respect of electric lighting works, and that the committee be authorised to apply to the Local Government Board for powers to borrow money for the purpose. The Council had already spent over £1,000 in enquiries and preparations, and in order to prevent any private company coming in to take advantage of the provisional order which the Board of Trade had granted to the Corporation, he thought they would be unwise not to proceed. Alderman Spary moved as an amendment: "That no further proceedings be taken or expense incurred by the committee with regard to the introduction of electric lighting into the borough until the question has been referred to a poll of the ratepayers by ballot or voting papers," but this proposition was ruled out of order, and Mr. Nuttall moved a further amendment deferring the question, and it was eventually decided that the matter should be left to the Town Hall and Electric Lighting Committee, who had hitherto had the management of the whole affair, and the question will therefore come up for rediscussion on February 2.

South Staffordshire Tramways.—Speaking at the tenth annual supper to the employés of the company at Darlaston Town Hall, Mr. S R. Bludstone (vice chairman of the company) said it was well known that the license to work the steam trams would expire with the close of the year, and there was a widespread expectation that the service would be discontinued from that date, but that was not his opinion. The West Bromwich and Handsworth authorities desired the substitution of a cable system for the steam traction; but that was impracticable, because the cost would be too great, and there was not sufficient traffic to warrant the directors in incurring such a great expenditure. The whole of the authorities—those of West Bromwich in particular—he had no hesitation in saying would be consulting the interests of the inhabitants of their districts if they accepted the overhead electric system. As to the difficulties connected with the continuance of the contract for the running of that system between Walsall, Wednesbury, and Darlaston, he hoped and believed that they would be overcome, although the Electric Construction Company were trying to screw another penny per mile—viz., 9d instead of 8d.—out of the company. As a matter of fact, there were portions of that branch of the system which did not pay the tramway company even at 8d per mile They had spent during the last six months twice as much upon the permanent way as during the six previous months, and now the permanent way was in a perfectly satisfactory condition. In fact, the plea that the condition of the road bed and rails was causing damage to the cars was nonsense; and if the cars were not in a good condition, it was because the electrical company were now doing their own repairs, instead of having them done, as previously, in the South Staffordshire Company's shops.

Dublin.—A deputation from the Dublin Southern District Tramway Company have waited on the Pembroke Town Commissioners with reference to an extension of their tramway line. Dr. Carte, chairman of the tramway company, said it was proposed to extend their system through parts of the Pembroke township. The first line that they wished to construct was from the head

Digitized by Google

of the Appian Way along Clyde road to Ball's Bridge. The second was along Eglinton road, joining the Clonskeagh and Donnybrook road and the Anglesea road to the show grounds at Ball's Bridge There would be a small junction between the Donnybrook and Stillorgan roads Then they were going to Ringsend and Irishtown to join the existing line. They proposed to run through Brunswick street to Ringsend The last bit asked for was from Baggot-street Church along Pembroke road to the corner opposite Lansdowne-road. They proposed to use electricity as the motive power on the new lines, and were going now for an Order in Council, which they as an existing company had to do. The electric cars would run so smoothly that no nuisance would be constituted by them in the way of noise. In America, tramcar accidents had diminished since the introduction of electricity. This arose chiefly from the fact that there was so much more control over an electric car. A horse car could not be stopped in less than a length and a half, while an electric car could be stopped in 6ft. or 7ft The Chairman said that they did not yet know the wishes of the majority of the Board on this subject; and Mr. Murphy suggested that the Board should give a general assent to the proposal to introduce electric lines, reserving power subsequently to insist on any reform of electric traction that they wished He thought it probable that the Corporation and the Rathmines Commissioners would assent to this course The deputation then withdrew, and the matter was referred to the Parliamentary Committee.

Audits.—The following correspondence has been sent to the *Times* for publication: "Sir,—The attention of the council of this institute was directed to an advertisement which appeared in the *Times* of November 29 last giving notice that at a general meeting of an electric light supply corporation a proposal would be made: 'That in order to save the trouble and expense of a double yearly audit it be and is hereby resolved that the auditor appointed by the Board of Trade for the official audit should also act as the shareholders' auditor.' I was instructed to write to the Board of Trade, and to ask whether in their opinion an official auditor of that Board is at liberty to accept the appointment of shareholders' auditor in an electric light company, and to point out that the functions of an official auditor and a shareholders' auditor are not only different, but to some extent conflicting. In reply, I have received a letter from the Board, a copy of which I enclose, and which I shall be glad if you will publish in your next issue—I am, sir, your obedient servant, W. G. HOWGRAVE secretary, Institute of Chartered Accountants in England and Wales" "Board of Trade (Railway Department), 7, Whitehall-gardens, London S W., 18th December. 1895. Electric Lighting Acts, 1882 to 1890. Sir,—With reference to your letter of the 5th inst, calling the attention of this Department to a resolution dealing with the question of the audit of the accounts of the . . . which it is proposed to submit to the next general meeting of the shareholders of the . . . . I am directed by the Board of Trade to state that they hold it to be outside the province of the auditor appointed by them under the terms of the provisional order granted to the company to act as auditor on behalf of the shareholders I am further to state that the audit conducted by this auditor is of a different character to that of a shareholders' audit, and has in view different objects, and it appears to the Board of Trade that it rests with the company to determine whether they are acting legally if they entirely dispense with the audit contemplated by the Companies Acts.—I am, Sir, your obedient servant, FRANCIS J. S. HOPWOOD. The secretary to the Institute of Chartered Accountants, Moorgate-place, E.C."

Bath.—On the motion of Alderman Sturges, it was agreed at the last meeting of the Urban Sanitary Authority that the seal of the Authority should be fixed to the memorial to the Board of Trade for the grant of the provisional order. Alderman Sturges referred to the issue of the report of Mr. Hammond on the electric lighting question. It was a "very exhaustive and masterly production, requiring a great deal of thought" The Lighting Committee had not yet met to consider it, but when they did so it would be their duty to send up a recommendation This would be the work of the near future The substance of Mr. R. Hammond's report to the Lighting Committee of the Urban Sanitary Authority on the value to the city of the property (or any portion thereof) of the City of Bath Electric Lighting and Engineering Company, Limited, is as follows. It deals with the subject under three heads: (1) The desirability of electricity works being laid down by the Corporation; (2) the system of generation and distribution best suited to the city, and (3) the advisability of the acquisition of the existing electric light works. Mr. Hammond thinks it must be conceded (*a*) it is the universal experience that even in places where gas is supplied at a very low rate there is a sufficient number of enlightened private consumers to make electricity supply a paying business; (*b*) electricity supply works dealing with both public and private lighting are becoming general; (*c*) where works have been laid down on sound lines they are proving a financial success; (*d*) the tendency is for local authorities to lay down their own works, and in all cases to obtain powers to deal with both public and private lighting; (*e*) there is great probability of decreased costs as the business extends; (*f*) electricity supply works for private lighting laid down by a corporation are likely to be more economically carried on than works laid down by a company, and therefore afford a cheaper supply to the ratepayers; (*g*) statutory powers for the establishment of works for private lighting may become of great value to the community, and should be vested in the Corporation. On the question of the system to be adopted, Mr. Hammond discusses various systems at length. Judging Bath to be a progressive city, he points out that it is imperative that the pioneer system should be one of great elasticity, and capable of almost indefinite extension. An inspection of the area of Bath shows that the demand for electrical energy will probably eventually come from widely-scattered points, which can only be economically coped with by high-tension feeders. The system which he considers best for the city is the one that is at present used by the local company. On the question of the advisability of the acquisition of the existing electric light works, Mr. Hammond considers it safe to prognosticate from the decisions of the Board of Trade, in similar cases, that they will refuse their consent to the application of the company and grant that of the Corporation. He goes on to point out the desirability of a friendly settlement on lines equitable to the conflicting interests It would have the warm approval of the Board of Trade. The generating plant of the company, Mr. Hammond states, is not of the latest type nor of the highest efficiency. Some of the remaining apparatus is, however, of excellent quality and quite suitable for the work which it has to do It is evident that if on the expiry of the company's license the plant were sold off it could only be realised at a disastrous sacrifice. Whereas, on the other hand, if the Corporation were laying down their own works, there are some portions of the company's plant which could not be procured at a lower figure than that at which they stand on the company's books. After adverting to the fact that the space for extension at the present works is limited he remarks that he does not consider that the idea of two separate works should be dismissed as impracticable, but obviously they could not be worked as economically as central works together. In the matter of distribution, however, advantage would accrue from feeding from two distant points, and if the present works could be obtained at a fair price, it might suit the Corporation very well to begin their operations there. Mr. Hammond then goes into a careful consideration of the company's buildings and plant, incidentally mentioning that everything bears the impress of careful and painstaking management The total of his valuation (excluding the land which he thinks should be valued by the surveyor) amounts to £29,285. Considering alternatives to purchase, he remarks that if the Corporation fail to come to terms with the company they can, of course, lay down their own works, whether at the Bathwick Mills, where the waste gases would prove a useful adjunct for working the day load, or at the destructor, where the water power would prove of service. On the question of profits, he states that the improvements which he suggests in the works would tend to very much cheaper working, and he thinks that with 10,000 lights already connected, and a revenue of over £5,000 a year, a profit sufficient to cover the interest and sinking fund might be relied upon from the very start
